Recently, Hedrick *et al.*[8] isolated a cDNA clone (TM86) which is T cell-specific, localized on membrane-bound polysomes and systematically rearranged in a variety of T-cell lines and hybridomas. Sequence analysis of this and related cDNA clones (86T1, 86T3 and 86T5) indicates significant similarity to immunoglobulin variable and constant regions and an independently assorting 16-amino acid element homologous to both heavy- and light-chain J regions[9]. Antisera raised against synthetic peptide fragments of this molecule significantly inhibit the *in vitro* response of certain T-helper (T_H) hybridomas (J. Rothbard *et al.*, in preparation). Thus, it seems probable that these cDNAs encode one chain of the murine T-cell antigen receptor. Other workers[10] recently isolated a cDNA clone from a human T-cell lymphoma line which appears to encode a closely related molecule. To investigate the structure of the genes encoding these molecules and the rearrangements that occur at the genomic level during T-cell differentiation, we examined the pigeon cytochrome *c*-specific, H-2E-restricted T_H hybridoma, 2B4 (ref. 11). A monoclonal antibody specific to this particular line has been isolated and shown to precipitate a 43,000 (43K)-molecular weight disulphide-linked heterodimer[11] characteristic of the murine receptor for antigen[12,13].

Sequence of a 2B4 cDNA clone

A library of cDNA clones from 2B4 mRNA was constructed as described elsewhere[14] in the vector λgt-10 (ref. 15). Phage were screened with 86T5, a cDNA clone largely containing constant region sequences of the putative receptor molecule[9]. Approximately 0.02% of the clones were positive, of which two distinct types were evident: one of these derives from the fusion partner BW5147 and will be described elsewhere—the other type appears to be specific to the 2B4 hybridoma and the structure and sequence of a representative clone, p2B4.71, is shown in Fig. 1. The amino acid numbering system is that of the mature protein, assuming a signal peptide cleavage 19 amino acids from the initiation condon[9] (by analogy to immunoglobulin). Unlike the previously described murine cDNAs[9], p2B4.71 possesses a complete 3′ end with a stop codon after amino acid 287 and a 3′-untranslated region of 174 nucleotides, ending with a poly(A) addition signal 17 nucleotides 5′ to the poly(A) tail. The 5′ end is not complete as shown, but we were subsequently able to deduce the remaining variable region–leader polypeptide sequence from the genomic clones (see below).

The amino-terminal portion of the constant region (amino acids 115–241) has only one nucleotide change (silent) at amino acid 201. However, after position 241, the nucleotide sequences diverge significantly (15%) (Fig. 1). Interestingly, the amino acid sequence is relatively unchanged (only four amino acid changes result from 22 nucleotide changes). Although these differences could have been due to divergence between strains of mice in a single gene (86T1 is from BALB/c and p2B4.71 is from B10.A), our recent data indicate that the constant regions of these cDNAs are derived from two different genes and that the regions of similarity and divergence are encoded in separate exons[42].

Also interesting is the fact that the same *J* region used in TM86 (ref. 9) appears again in the 2B4.71 sequence but joined to a different variable region, further confirming the ability of these elements to assort independently of the variable regions. TM86 derives from a T_H hybridoma, 3.3T (ref. 4), which responds to a cytochrome *c* fragment different from that of 2B4, but using the same MHC backgrounds (B10.A (2R) for 3.3T and B10.A for 2B4). While the 5′ regions do not appear to be similar, it may be significant that they share the same *J* region. In contrast to the TM86 fragment, the p2B4.71 variable region shows significant similarity to that of 86T1, which was obtained randomly from a thymocyte library[9]. Homologous residues are indicated by asterisks in Fig. 1. In all, 31/90 (34%) residues in the portion of variable region shown are identical; most of these are located in the same regions that are relatively invariant (framework residues) in both heavy- and light-chain immunoglobulins[16]. Although it will be necessary to sequence many more T-cell variable regions to be certain, this comparison indicates that the structure of the receptor binding site may be very similar to

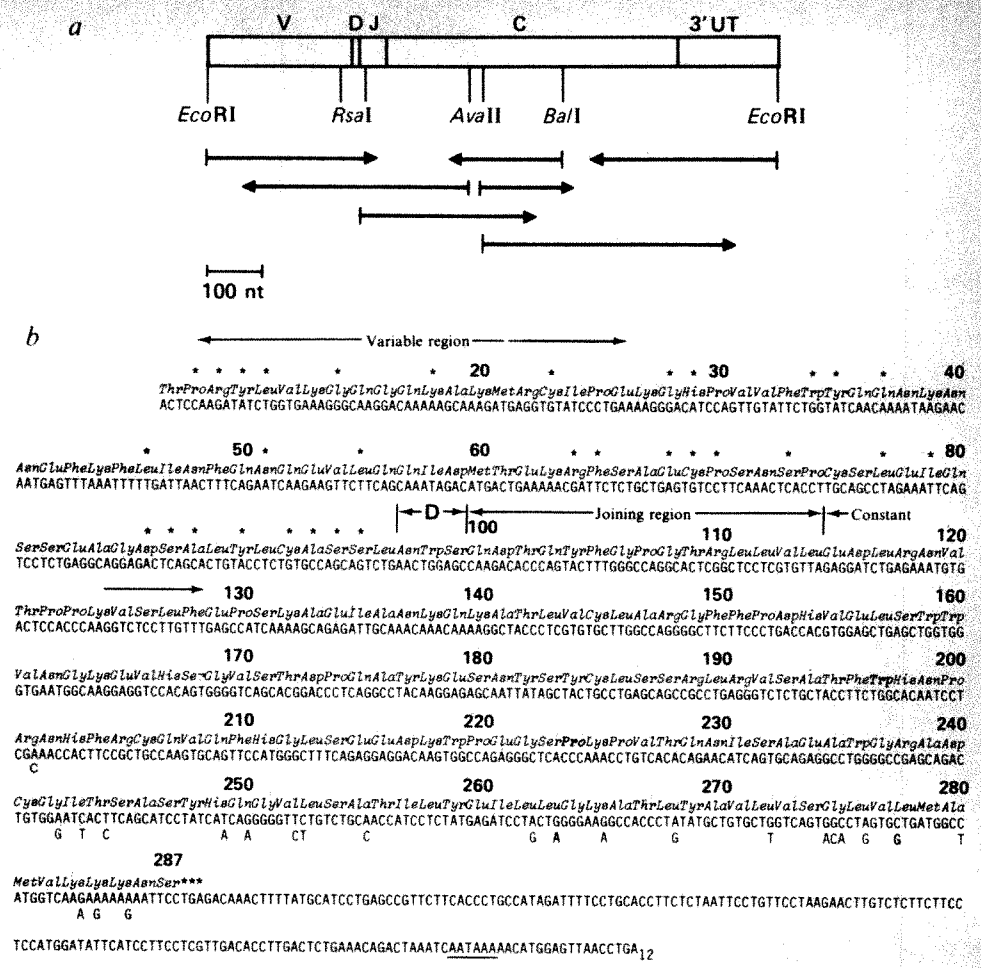

Fig. 1 Sequence of 2B4.71.A cDNA library of ~200,000 recombinants was constructed as described[14] using poly(A)$^+$ cytoplasmic RNA from the T-helper hybridoma, 2B4. The library was screened by standard procedures and positive clones subcloned into pUC9 (ref. 18) for further characterization. One such clone, p2B4.71, was sequenced using the procedures of Maxam and Gilbert[19]. The sequencing strategy is shown in *a*. The sequence starts after the *Eco*RI linker site. Residues marked by asterisks are those homologous to the variable region of 86T1. Nucleotides beneath the constant-region sequence represent differences compared with the constant-region sequence of 86T1.

that of immunoglobulins with respect to framework and complementarity determining residues.

Corresponding genomic clones

To characterize the gene which gave rise to the p2B4.71 cDNA clone, as well as to reconstruct the recombinational events which must have occurred in its formation, we prepared λ genomic libraries[17] of both 2B4 tumour DNA and B10.A liver DNA. The 2B4 library was screened with constant-region probes and the liver libraries were screened with separate variable- and constant-region probes. Figure 2 shows the restriction maps of the resulting clones. The B.6 clone contains an unrearranged (presumably germ-line) variable region from the B10.A genomic library. Three overlapping clones (B.21, B.22 and B.3) containing constant-region genes were isolated from the liver DNA library. Southern blotting analysis showed that all the constant-region genes in the mouse genome are contained within this 25-kilobase (kb) region. Further analysis showed that these consist of two constant-region genes, each with a distinct *J*-region cluster[42]. Two sets of genomic clones were isolated from the 2B4 hybridoma library. One set represents the result of an apparent rearrangement and will be described elsewhere. The other set, represented by 2B4.1 and 2B4.9, encode all of the gene segments of p2B4.71. As with the case of immunoglobulins, the rearranged genes appear to result from the recombination of a variable region and its 5′ flanking sequences with a *J*–*C* locus and its 3′ flanking sequences, as indicated by the shading in Fig. 2. The homologies indicated were determined by heteroduplex analysis (data not shown), restriction mapping and sequence analysis.

Variable region formation

In order to analyse the assembly of the variable-region exon, we subcloned the relevant restriction fragments from λ clones 2B4.9, B.21, B.22 and B.6 into the plasmid vector pUC9 (ref. 18) and sequenced them by the procedure of Maxam and Gilbert[19]. Figure 3*a*, *b* indicates the sequencing strategy for the rearranged variable-region fragment and the corresponding liver segments. The strategy used to sequence the *J* region is shown in Fig. 4 as part of the larger region (see below). The sequences themselves are shown in Fig. 3*c*, together with the predicted amino acid residues. The indicated leader polypeptide exon is deduced from the very close similarity that the 2B4 sequence

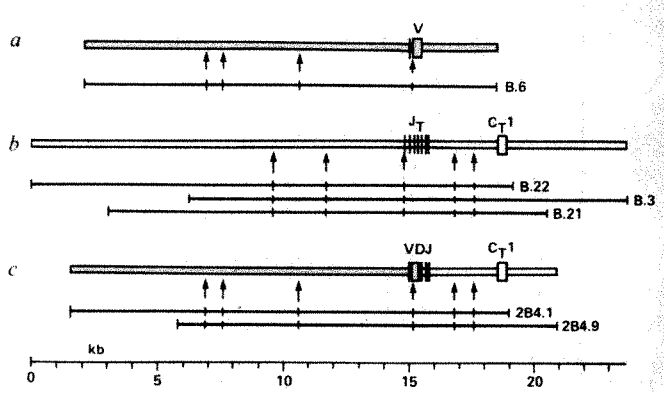

Fig. 2 Genomic clones from liver and hybridoma libraries. Shading indicates similarities between clones as determined by restriction mapping and heteroduplex analysis. ↑, *Eco*RI sites. Assignment of variable (*V*) and joining (*J*) elements is based on the sequence analysis and that of the first constant-region exon[42]. All clones are shown 5′ to 3′ with respect to the coding regions. B10.A liver and 2B4 T-helper hybridoma DNAs were partially digested with *Mbo*I, size-selected on sucrose gradients and ligated to *Bam*HI-digested arms of the λ vector J1 (a derivative of L47.1) (ref. 39) and packaged *in vitro* as described elsewhere[17]. The T_H hybridoma library was screened with a predominantly constant-region probe (86T5)[9]. The liver DNA libraries were screened with both constant-(86T5) and variable-region probes from p2B4.71.

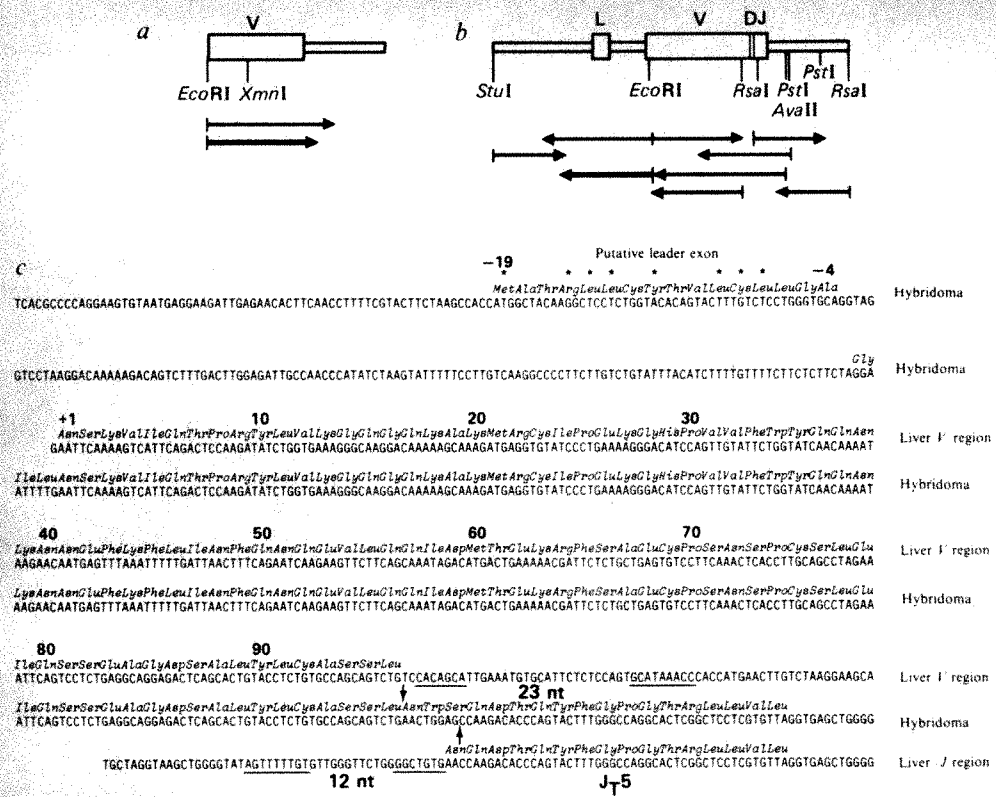

Fig. 3 Assembly of the 2B4 variable region. The sequencing strategy for the liver (*a*) and 2B4 (*b*) derived variable-region fragments. The *J*-region sequence is taken from the data presented in Fig. 4. Thin lines indicate 5′-end labelling with polynucleotide kinase and thick lines indicate 3′-end labelling with the large (Klenow) fragment of DNA polymerase I[19]. The sequences are shown in *c*, with the apparent leader exon (residues homologous to the 86T1 leader are marked with asterisks) and the variable, diversity and joining region components as indicated. Putative signal sequences for DNA rearrangement, separated by 23 and 12 nucleotides (nt) respectively, are underlined. Arrows indicate the apparent points of rearrangement.

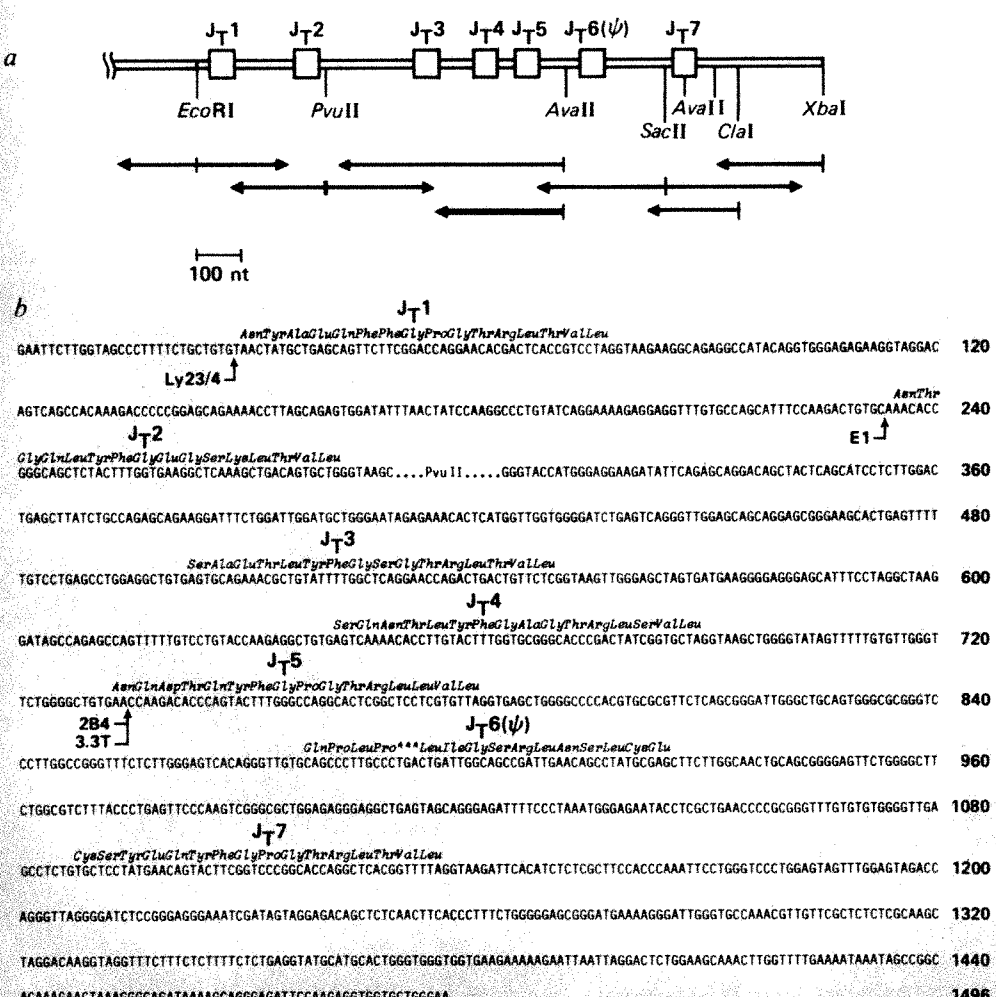

Fig. 4 *J*-region cluster. The fragment indicated from the genomic clone B.22 was sequenced by the strategy shown in *a*. Thin lines indicate 5′-end labelling and thick lines represent 3′-end labelling. Apparent J_T elements were identified based on amino acid and flanking sequence homologies to expressed J_T regions[9]. The stop codon in the J_T6 pseudogene is indicated by ***. The apparent points of rearrangement of p2B4.71(2B4) and of TM86[9] (3.3T) as well as those of cDNA clones derived from E1 (ref. 40) and Ly 23/4 (ref. 41 and P. Patten *et al.*, unpublished results) are indicated by arrows.

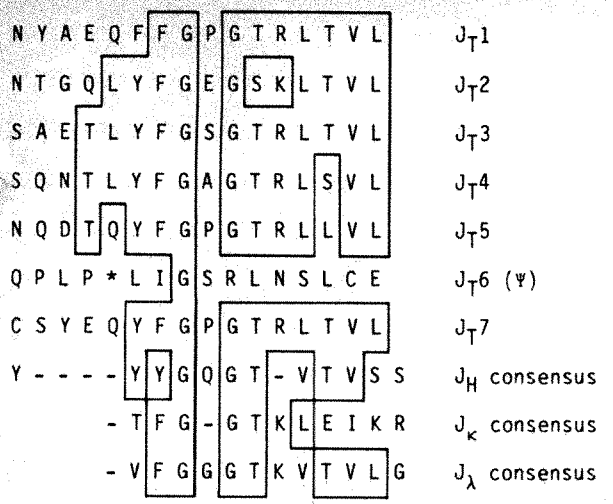

Fig. 5 Amino acid homologies between the seven *J*-region elements. Comparison of the coding sequence homologies between the *J* regions and the consensus sequences from the three different types of immunoglobulin[16].

as to that of 86T1 (ref. 9) (8/15) residues at identical positions). This assignment is probably correct because of the virtual identity that these presumptive intron–exon boundaries have with immunoglobulins[20].

Figure 3*c* also shows that an 8-nucleotide sequence at the 3′ portion of the rearranged variable region is not derived from either of the two liver DNA sequences. This sequence is at a position similar to the *D* or diversity region in immunoglobulin heavy chains and codes for a similar number of residues[21–25]. Although we cannot exclude the possibility that this extra sequence is not encoded in the germ line[26], it does bear an intriguing resemblance to that of an immunoglobulin *D* element, Q52 (CAACTGGAC)[22]. As recent data show that this gene is not located on the same chromosome as the mouse heavy-chain locus[43], this homology might derive from some functional constraints on the *D* region common to both the T-cell receptor and immunoglobulins. The existence of a family of such elements for the T-cell molecule could greatly increase the number of possible variable regions by at least three mechanisms known from the example of immunoglobulin genes: combinatorial association of a third genetic element[21], variability in the junction points at the DNA level[21,23], and the possibility of reading in different frames[27].

It is important to compare the unrearranged *V* region with the corresponding 294 nucleotides of the hybridoma gene. Within this region there is complete homology between the hybridoma and liver-derived gene sequences. This indicates that no somatic mutation has occurred between the putative germline and the active gene, and while this does not rule out a role for such mutation in other contexts, it does make some of the more extreme models of receptor adaptation to self-MHC and antigen less likely[28].

Also significant is the fact that by combining the complete, processed *V(DJ)* region sequence shown in Fig. 3*c* with the complete constant region of Fig. 1*b*, we can deduce a molecular weight of 32.1K. This is in very close agreement with the value of 31K obtained in tunicamycin studies of the unglycosylated murine receptor peptides[29].

Directly 3′ to the *V* region of the germ-line DNA in Fig. 3*c* is the sequence CACAGCA-[23 nucleotides]-GCATAAACC which is similar to the putative signal sequences for gene segment fusion 3′ to the immunoglobulin *V* regions[30,31]. In immunoglobulins, the sequence is typically CACAGTG-[11 or 22 nucleotides]-ACAAAAACC 3′ to the *V*[22,27]; the inverse of the putative *J*-region signal sequences (see below). Although the analysis of one *V* region is insufficient to establish exact sequence requirements, it seems significant that the last two nucleotides of the putative *V*-region heptamer (CA) and the first nucleotide of the nonamer (G) have never appeared in those positions of the relevant immunoglobulin sequences. These similarities and differences compared with immunoglobulin flanking sequences are discussed more extensively with the *J*-region data below.

J-region cluster

Sequence analysis of the liver DNA-derived clones in the region immediately surrounding the point of rearrangement (Fig. 1) indicates the presence of a cluster of seven *J* regions. Three of these *J* regions (J_T1, J_T2 and J_T5) have been found expressed in different cDNA clones (see Fig. 4 legend), and as many as six may be functional. J_T6 is clearly not functional because of the in-frame stop codon. Figure 4 shows the sequencing strategy of the 1.8-kb fragment containing the *J* regions. The J_T cluster begins ~3.6 kb 5′ to the first constant-region domain[42]. The J_T elements are very closely spaced at 40–220 nucleotides apart, whereas immunoglobulin *J* regions are typically 300–500 nucleotides apart[22,30,31]. The *J* region used by p2B4.71 and TM86 (ref. 9) is the fifth in the cluster (J_T5) and, as indicated in Fig. 4, joining occurs at the same position for each. Of particular interest are the putative signal sequences for gene segment fusion 5′ to each *J* region. In immunoglobulins, these sequences, spaced either 10–12 or 21–23 nucleotides apart, are highly conserved between all functional *J* regions in a variety of species[21,22,30,31]. The sequence is typically GGTTTTTGT-[11 or 22 nucleotides]-CACTGTG 5′ to *J* or *D* elements and the inverse: CACAGTG-[11 or 22 nucleotides]-ACAAAAACC 3′ to *V*. The sequence 5′ to three of the *J* regions in Fig. 4 is AGTTTTTGT-[12 nucleotides]-GGCTGTG. The other sequences diverge slightly from this consensus. Although these sequences are very similar to those of the immunoglobulin genes in all cases, the heptamer is not palindromic and the sequence 'GG' has not been found in any of the many immunoglobulin sequences in this position in either mouse, human or rat[16]. The region immediately 3′ to the apparent functional *J* regions also contains conserved sequences, as indicated in Fig. 4, but these may have more to do with RNA splicing than recombination. We conclude that the gene segments examined here have sequences which are analogous to those used by immunoglobulins for variable-region assembly but that they differ slightly in the conserved sequence,

Fig. 6 Flanking sequence homologies among *J* regions both 5′ and 3′ (see text); homologies are underlined.

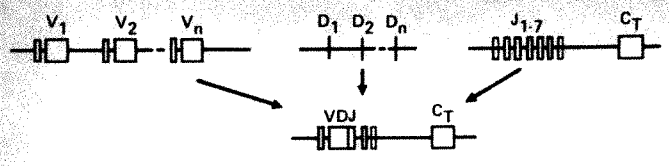

Fig. 7 Model of 2B4 T-cell receptor gene rearrangement. Variable (*V*), diversity (*D*) and joining (*J*) region elements all appear to contribute to the formation of the 2B4 gene examined here.

perhaps to allow independent regulation of rearrangement in T and B cells. Another possibility is that there is no functional difference between the flanking sequences of the T-cell *J* regions and those of immunoglobulins; this would account for the non-functional *D–J* joining found in some T-cell clones[25] and would suggest that the usual B cell/T cell specificity of rearrangement is dependent on other signals. No immunoglobulin light-chain rearrangement has been observed in T cells and we have not seen any rearrangement of the T-cell locus discussed here in three different B-cell lymphoma lines, nor in a macrophage line.

Figure 5 illustrates the homology between *J* regions of the cluster described here in the potential coding residues. As with *J* regions in any specific immunoglobulin family, all except the pseudo-*J* are highly homologous. Note also that the previously identified (from cDNA clones) 86T1/86T5 *J* region[9] is not within this cluster, nor is another *J* region found in a cDNA clones from a concanavalin A-stimulated spleen cell library (unpublished results). These and other J_T regions appear to reside in a second cluster 5′ to the one examined here[42].

Implications for antigen recognition

The T-cell gene studied here bears a remarkable resemblance to those of immunoglobulins in amino acid sequence, patterns of rearrangement and the sizes and positions of the different gene segments. Even the flanking sequences relevant to rearrangement differ only slightly. These similarities must reflect the common origin of these genes in evolution as well as the strength of the selective pressures involved. Also interesting is the complexity of the rearrangements (see Fig. 7); the formation of the variable-region exon requires as many gene segments (*V*, *D* and *J*) as the most complex of the immunoglobulins. This is in contrast to the expectation that the T-cell receptor should represent a simpler type of gene (perhaps like light-chain immunoglobulins) because cell-mediated immunity may have arisen earlier in evolution than humoral (antibody-mediated) immunity. Instead, it seems that the T-cell gene is at least as complex as the most elaborate of the immunoglobulin genes and that T-cell recognition of antigen and MHC may involve a range of specificities equivalent to that of immunoglobulins. It is also interesting to note that the '11-22' rule[21] which in B-cell heavy chains may only permit *V* and *J* segments to join to *D* (and not to each other) does not exclude direct *V–J* joining in the example seen here. If such direct joining is possible, it would provide additional flexibility in the formation of the variable region of this molecule.

The similarities to immunoglobulins noted above seem to place considerable constraints on the structure of the second chain of the receptor heterodimer. The intertwining of the heavy- and light-chain polypeptides with each other in immunoglobulins as defined by X-ray crystallography[32,33] makes it unlikely that one chain could be so similar to immunoglobulin and the other chain very different. This idea is reinforced by the peptide mapping data indicating variable and constant portions of both chains[34–36]. Therefore, one would expect the second chain to be very similar to the one described here and that the combining site formed must resemble that of immunoglobulin. Indeed, even the possible hypervariable and framework residues seen in the comparison with 86T1 and p2B4.71 (Fig. 1) fall into almost the same positions as those of immunoglobulin. This favours the one-receptor model of antigen–MHC recognition, but introduces the unexpected paradox of how to account for all the additional requirements of T-cell recognition and thymic learning in a molecule that is as yet indistinguishable from immunoglobulins. One possibility is that a low-affinity interaction with self-MHC occurs in the thymus which eliminates T cells which either cannot bind to self-MHC at all, or bind too tightly. Evidence has been obtained for the existence of highly self-MHC-reactive cells being present in, but never leaving the thymus (B. Benaceraf, personal communication). Perhaps only those cells with a low affinity for self-MHC can emerge from the thymus and are available to recognize antigen–MHC complexes, which they presumably do at some higher affinity. Alternatively, the receptor molecule could be largely used in binding antigen while the MHC interaction depends more on accessory molecules such as L3T4 in helper T cells[37] and Lyt 2,3 in cytotoxic T cells[38]. The availability of cloned probes and detailed structural data should considerably aid experiments designed to test this and other models.

We thank T. Huynh for the λgt-10 and J. Mullins for the λJ1 vectors; R. W. Davis for the use of the electron microscope; L. Herzenberg for critical reading; and K. Redman for preparation of the manuscript. N.R.J.G. is a fellow of the Cancer Research Institute of New York. This work was supported by grants to M.M.D. from the NIH (AI19512 and AI20320) and the American Cancer Society (IM00364).

The 3 Å electron density map of a co-crystalline recognition complex between Eco*RI endonuclease and the oligonucleotide TCGCGAATTCGCG reveals that a tight, complementary interface between the enzyme and the major groove of the DNA is the major determinant of sequence specificity. The DNA contains a torsional kink and other departures from the B conformation which unwind the DNA and thereby widen the major groove in the recognition site.*

THE interactions between proteins and specific DNA sequences are key regulatory events in the control of many biological processes. A full understanding of the recognition mechanisms which determine these interactions requires detailed knowledge of the structure of representative DNA–protein interfaces. This knowledge may also reveal general recognition rules which could govern a broad range of DNA–protein interactions. Recently, the crystal structures of several proteins which recognize specific sites on DNA have been solved[1–5]. In the absence of DNA–protein co-crystals of high quality, these protein structures alone have provided the basis for extensive model building and speculation concerning the appearance of the recognition complexes[1–8]. However, these studies are limited by the necessary assumption that significant conformational changes do not occur in either the protein or the DNA. Similarly, crystallographic studies on B-DNA have revealed detailed information on the structure of DNA in the absence of protein[9–14]. We report here our preliminary observations of the first sequence-specific DNA–protein complex to be visualized by X-ray diffraction methods: *Eco*RI endonuclease complexed with the synthetic oligonucleotide TCGCGAATTCGCG (*Eco*RI site underlined).

Solution of the structure

*Eco*RI endonuclease and TCGCGAATTCGCG co-crystallize in space group P321 with one 32,000-molecular weight enzyme subunit and one strand of DNA in the asymmetric unit, as reported previously[15]. The crystals were grown in the absence of Mg^{2+}, which is required for cleavage of the DNA. Data were collected by oscillation film photography as described previously[15] on the native crystal and on platinum and mercury derivatives. The platinum derivative was obtained by soaking crystals in 10 mM *cis*-$(NH_3)_2PtCl_2$, dissolved in 40 mM bis-tris-propane (BTP), *p*H 7.0, plus a mixture of 11% w/v polyethylene glycol (PEG) 6000 and 5% w/v PEG 400 for 7 days at 25 °C. The Hg derivative was similarly obtained by soaking crystals in 5 mM $Hg(SCH_2CH_2NH_3^+)_2$, dissolved in 40 mM BTP, *p*H 7.0, plus 16% w/v PEG 6000 for 3.5 days at 25 °C. The heavy atom locations were independently determined by difference Patterson methods for both derivatives. (Even though the platinum compound is a chemotherapeutic agent which appears to act at the DNA level, the location of the major and minor sites are found on the surface of the protein, well away from the DNA.) The Cullis *R* factors for the Pt and Hg derivatives to 3.5 Å are 49.2% and 52.2%, respectively.

A multiple isomorphous replacement (MIR) electron density map was calculated from these two derivatives to 5 Å resolution. In addition, Wang's iterative single isomorphous replacement (ISIR) method (B.-C.W., in preparation) was independently applied to the Pt and Hg data. This procedure identifies protein and solvent regions in a SIR electron density map and uses this information to resolve the SIR phase ambiguity. The general features, such as the solvent regions and the molecular outline, were similar in all three electron density maps; however, the MIR and Hg-ISIR maps contained significant amounts of noise, while the Pt-ISIR map was very clear. We suspect that the noise is associated with non-isomorphism in the Hg derivative (even the Pt derivative was not strictly isomorphic beyond 3.5 Å). We therefore used the ISIR method to resolve the phase ambiguity in the 3.5 Å Pt SIR phases. The ISIR method was also used to extend the phase information in successive stages to 3.2 and 3.0 Å resolution. The mean figures of merit for the 3.5 and 3.0 Å phases are 0.78 and 0.79, respectively. Electron density maps calculated with the 3.5 and 3.0 Å Pt-ISIR phases were very similar apart from the expected greater detail in the higher resolution map. Both maps showed clearly recognizable features, including the α-helix seen in Fig. 1. The enantiomorph was chosen so that α-helices were right handed.

The DNA was easily located in the 3.0 Å map and coordinates were obtained for the centroids of all 12 phosphate moieties, the 13 sugars and 12 of the bases. These coordinates enabled us to calculate the general DNA conformational parameters via the helix determination procedures developed in conjunction with the ApU and GpC structures[16] as well as to construct Figs 2 and 3.

Structural features

Inspection of the Pt-ISIR electron density map revealed several striking features which were clear before a complete tracing of the polypeptide chain and fitting of molecular models. These broad features are discussed below.

The DNA–*Eco*RI endonuclease complex is a symmetrical globular structure ~50 Å across (Fig. 2). The molecular boun-

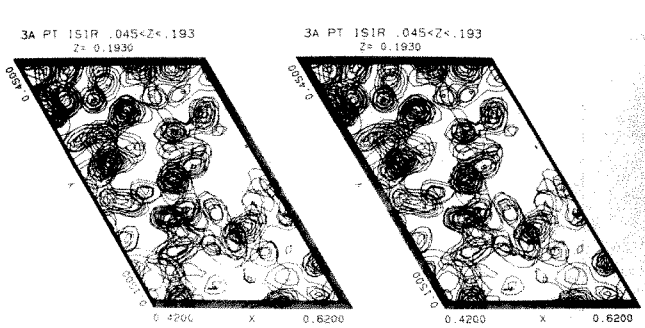

Fig. 1 A representative α-helix. A stereo pair showing a portion of the 3.0 Å ISIR electron density map illustrating the general quality of the map. An α-helix runs vertically up the page (this is not the α-helix discussed in the text which interacts with the DNA).

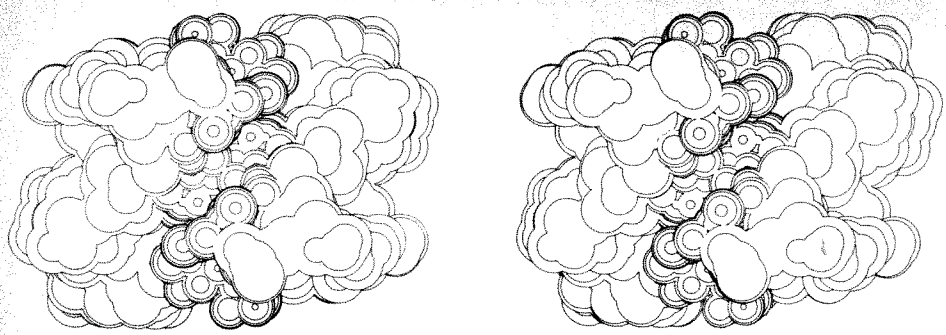

Fig. 2 The DNA–*Eco*RI endonuclease complex. This schematic representation of the surface of the DNA–protein complex was constructed by superimposing spheres on the electron density map so that their surfaces followed the molecular boundary. The DNA is shaded more darkly than the protein. The complex is viewed from the solvent region, looking down the crystallographic 2-fold symmetry axis. The DNA is clearly embedded in the protein and the active sites for recognition and hydrolysis are underneath the DNA.

dary clearly encloses a well defined complex consisting of two enzyme subunits and one double helix. The two protein subunits and the two strands of DNA are related by a common crystallographic axis of 2-fold symmetry, as expected from the contents of the asymmetric unit[15].

The packing of these complexes within the crystalline lattice is typical of that generally seen in macromolecular crystals, that is, a limited number of fortuitous interactions between symmetry-related complexes. One of these is a DNA–DNA interaction in which symmetry-related double helices are packed end to end, forming a continuous rod of DNA parallel to the *c*-axis. This is one of the common modes of packing found in crystals containing only DNA and probably contributes to the relatively strong diffraction pattern of this particular crystalline form of *Eco*RI endonuclease. The unpaired thymine moieties at each end of a double helix appear to be in contact with thymine residues from symmetry-related double helices.

The DNA conformation departs from the classical B-motif (Fig. 3). The 'distortions' are not uniformly distributed over the entire DNA molecule; rather they are concentrated in three abrupt transitions termed kinks. These kinks create four blocks of three base pairs each:

TCGC-GAA-TTC-GCG
GCG-CTT-AAG-CGCT

where the kinks are indicated by dashes. These features arise from systematic shifts in the coordinates of all the phosphate, sugar and base moieties in each intervening 3-base pair (bp) segment, that is, they represent local adjustments to net displacements of entire blocks of double helical DNA. These kinks are conceptually related to the model structures originally predicted by Crick and Klug[17], although they differ significantly in detail. Additional kinked models were proposed by Sobell *et al.*[18,19] and by Zhurkin *et al.*[20].

We suggest a flexible nomenclature for the DNA conformation because subsequent DNA–protein structures will probably reveal additional kinks and other novel DNA features. We refer to the overall DNA conformation as 'neo RI-DNA'. The specific context of neo relates to a DNA conformation which is stabilized by the binding of a recognition protein.

The left-most block will be referred to as the terminal or CGC block and the next block as the central or GAA block. The two blocks on the right (TTC and GCG) are identical to the respective left blocks because of the 2-fold symmetry axis.

We designate the transition between the symmetry-related central blocks (GAA–TTC) as the neo-1 kink and that between the terminal and central blocks (CGC–GAA) as the neo-2 kink. Neo-2 kinks appear twice within the structure (CGC–GAA and TTC–GCG) and both are identical by virtue of the crystallographic axis of 2-fold symmetry.

When the helical symmetry within each block was determined by analysing the geometrical relationships of the centroids of the phosphate and internal deoxyribose moieties according to the procedure of Rosenberg *et al.*[16], B-type parameters were found for the central block: 10.3 residues per turn with a helical displacement of 3.2 Å. The values for the terminal block appear more like those usually associated with A-DNA: 11.3 residues per turn and 2.7 Å per residue. The location of the helix axes and the apparent tilt of the bases with respect to these axes are also suggestive of B- and A-DNA in the two respective blocks.

We emphasize that we are not claiming that the blocks between kinks are identical to either 'classical' A- or B-DNA. Indeed, these designations must be considered tentative until our analysis has reached the point that sugar pucker and other detailed conformational parameters can be determined unambiguously. We also suspect that relatively smaller structural departures from exact helical symmetry will be noted within the blocks once the structure is carefully refined.

Comparison with other DNA structures

The DNA in our co-crystal is basically the dodecamer studied extensively by Dickerson and colleagues[9–14,21] with the addition of a 5'-thymidylate residue. The kinks described here differ significantly from the features reported by Dickerson *et al.*, suggesting that the neo RI-DNA structure is not stable in the absence of the enzyme. This does not exclude the possibility that the neo RI conformation exists transiently due to thermal fluctuations nor does it exclude the possibility that these transient states are kinetic intermediates of complex formation.

Dickerson's dodecamer structure also possesses A-like features in the region we have described as the CGC block[10]. This led Dickerson and Drew to suggest that *Eco*RI sites are B-like within the canonical hexanucleotide flanked by A-like regions[10]. Our structure appears to confirm this suggestion and to indicate that this trend is amplified in the protein–DNA complex.

The 10.3 bp per turn helical repeat of the central blocks is within the values of 10.0 to 10.6 bp per turn reported for DNA in solution[22,23], bound on crystalline surfaces[24,25] and in nucleosomes[26,27].

Nature of the kinks

The neo-1 kink, at the centre of Fig. 2, enlarges the grooves, thereby facilitating access by the protein to the bases. This kink is a prominent feature of Fig. 3*b*, where the backbone can be seen to 'jog' upward in the centre of the figure. The displacement increases the distance between those segments of DNA backbone which straddle the kink by ~4 Å. This is achieved by a systematic unwinding of the entire DNA molecule by ~25°, that is, the neo-1 kink is primarily a torsional dislocation of the double helix.

The neo-1 kink introduces a small bend in the DNA such that the helices of the symmetry-related central blocks are inclined at an angle of ~12° to each other. (This value is preliminary and it is anticipated that model fitting and refinement will result in adjustments to its value.) The bend is towards the minor groove, as suggested by Crick and Klug[17].

The neo-2 kink is different in several respects from neo-1. The neo-1 possesses 2-fold symmetry while the neo-2 kink is asymmetrical. The neo-2 kink does not involve a dramatic unwinding of the DNA; however, it introduces a larger bend of ~23° between the helix axes. This bend includes rolling motion towards the minor groove. The neo-2 kink may also represent an A–B junction.

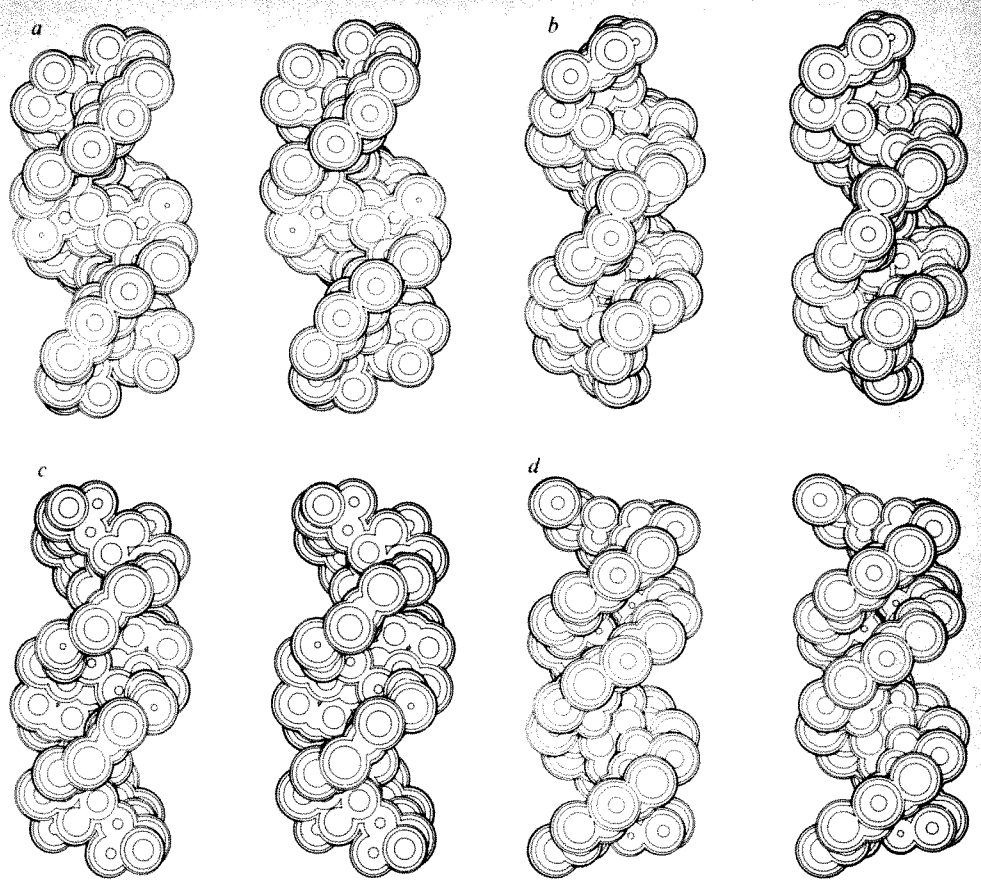

Fig. 3 The neo RI-DNA conformation. *a*, A stereo representation of the portion of the electron density corresponding to the DNA produced by placing spheres at the approximate positions of the phosphate, deoxyribose and base moieties (radii of 4, 3.5 and 3.5 Å, respectively). The view is from within the protein, towards the major groove where the sequence-specific recognition contacts are concentrated. The two parallel segments of DNA backbone running across the front of the figure are buried in clefts in the enzyme and include the phosphodiester linkages which would be cleaved in the presence of Mg^{2+}. *b*, The DNA rotated by 90° about the average helix axis. The neo-1 kink, which is between the two central blocks, can be seen in the centre. Note also the expansion of the major groove (which opens towards the left in the upper portion of the figure). *c*, The DNA rotated by 180° from that shown in *a*, that is, viewed from the solvent region as in Fig. 2. Kinks between the terminal blocks of 3 bp and the middle blocks can be noted in the backbone segments closest to the viewer. They are of the type described as neo-2 in the text. *d*, A similar representation of the B-DNA model which Arnott and co-workers[50] derived from fibre diffraction data.

Recent crystallographic observations of DNA structural variability *in vitro* have led to suggestions that DNA *in vivo* is structurally heterogeneous, and that structural variations may be associated with sequence-specific DNA–protein recognition[10,28]. The structural results include major departures from B-DNA, such as Z-DNA[28–31] as well as relatively smaller local variations within the B-motif[10,14,32,33]. The association between protein recognition and altered DNA conformation has been enhanced by the observation that DNA sequences which have the potential to form Z-DNA can be found within certain eukaryotic regulatory elements[34,35].

The kinks described here represent additional experimentally observed elements of DNA structural heterogeneity which are clearly associated with the binding of a recognition protein. The neo-1 kink is an essential element of the recognition event itself because the symmetry-paired α-helices (see below) cannot fit into the major groove unless that groove has been expanded via the neo-1 kink. This does not exclude an additional involvement of the kinks, especially the neo-2 kink, in the strand scission event also. This raises the expectation that DNA–protein recognition in general will turn out to be associated with specific deviations from the average B-double helix. The neo-1 and neo-2 kinks are probably general structural features that will be found in other DNA recognition systems. However, these generalizations cannot yet be established since this is the first X-ray structure of DNA in intimate association with a sequence-specific recognition protein.

DNA–protein interaction

The major groove of the recognition hexanucleotide (GAATTC) appears to be filled with protein, forming a large, complementary interface. All the base–amino acid interactions appear to be located in the major groove of the DNA, while the edges of the bases which are exposed in the minor groove are open to the solvent. Thus, the primary determinant of the recognition specificity is the direct interaction of complementary surfaces in the major groove. However, additional features of this structure raise the possibility of a second, indirect mechanism whereby sequences flanking the canonical hexanucleotide modulate the binding (see below).

A major component of the DNA–protein interaction is an α-helix which makes an angle of ~60° with the average DNA helix axis. There are two such α-helical structures, side by side, related by the crystallographic 2-fold symmetry axis. The polypeptide chain turns sharply at the end of each α-helix, leaving the amino acid residues at the end of the helix, in the bend and those in the adjacent stretch of chain in close proximity to the DNA.

Two symmetry-related pairs of amino acid side chains appear to be in contact with symmetry-related pairs of sequential adenine residues. These amino acid side chains are located in the α-helix-bend motifs described above, although each of the two physically adjacent side chains originates from a different protein subunit.

Flanking the recognition interface are two symmetry-related DNA backbone segments, those nearest the viewer in Fig. 3*a*, which are deeply buried in symmetrical clefts in the enzyme. These clefts extend from the bottom of the wide semi-cylindrical depression which contains the DNA, giving the protein a 'threaded' appearance. The buried backbone segments include the scissile phosphodiester bonds.

While the two 'arms' of protein enveloping the DNA from the upper left and lower right of Fig. 2 appear to originate in the underlying subunits, they might alternatively originate from symmetry-related molecules which are nearby due to crystal packing. We favour the interpretation that they are part of the underlying subunits because the electron density maps show extensive continuity with the underlying electron density and very limited continuity with the nearby, symmetry-related electron density. Furthermore, we have a provisional tracing of the polypeptide chain in this region in which each arm is a loop of protein which emerges from the underlying region. However, we emphasize that we cannot entirely exclude the alternative until we have an unambiguous tracing of the entire polypeptide chain.

If these arms do extend from the underlying protein, this would necessitate a conformational change in the enzyme during the complete catalytic cycle because the DNA could not get past the arms and enter the active site unless something moves. Such a conformational change has been implied by some of our biochemical results (ref. 36 and L.J.-J. *et al.*, unpublished). The conformational change could arise from two possibilities which are not mutually exclusive: mobility of the arms themselves and quaternary changes in which the two subunits in the dimer move with respect to each other.

Comparisons with inferred contact points

The DNA contact points described above show both similarities and differences when compared with the contacts inferred by Lu *et al.*[37] from the results of alkylation interference and protection experiments. They suggested contacts in the major groove (at the recognition guanine N^7 position) as well as phosphate contacts in good general agreement with our structure. Lu *et al.* also made two observations regarding the N^3 position of the central adenine, which is in the minor groove. This site was protected from dimethylsulphate by endonuclease, and prior methylation at this point blocked subsequent binding of the enzyme. They suggested that *Eco*RI endonuclease is in physical contact with the central adenine at N^3 (however, they also indicated that other interpretations were possible). We do not see any interaction between the protein and DNA at that position. This methylation site is in the region of the DNA most affected by the neo-1 kink and base–base steric effects could be responsible for these methylation results. Lu *et al.* also observed that while the N^3 of the adjacent adenine was protected by the endonuclease, prior methylation at this second point did not block subsequent binding of the enzyme. The factors responsible for this result are unknown, although we do not see any minor groove DNA–protein interactions there either. We therefore conclude that while alkylation protection and interference data can be used to infer a good low resolution indication of the location of the DNA–protein contacts, they cannot be reliably used to infer the precise points of DNA–protein interaction.

Another approach used to identify contacts on the DNA is based on the hydrogen bonding degeneracy rules of Seeman *et al.*[38–40]. In *Eco*RI endonuclease such degeneracy can be induced by conditions of elevated *p*H (8–9.5), Mn^{2+}, low ionic strength and by the addition of organic compounds such as glycerol or ethylene glycol[41–45]. This has been called the *Eco*RI* reaction[41] and the non-canonical sites so recognized are referred to as *Eco*RI* sites. We showed that hierarchies of base preferences could be discerned by qualitative estimations of the rate of cleavage at *Eco*RI* sites in plasmid DNA molecules. The observed hierarchies are uniquely predicted by a recognition model which assumes two major groove hydrogen bonds per base pair in standard conditions[40]. One or more of these are randomly replaced by a water–DNA hydrogen bond in *Eco*RI* conditions. The position of any *Eco*RI* sequence within the appropriate hierarchy is primarily determined by the number of remaining protein–DNA hydrogen bonds[40]. Woodbury *et al.*[39] reached similar conclusions from a somewhat different perspective. The major groove recognition points inferred from these analyses are in excellent agreement with our X-ray structure. Thus, degeneracy analysis appears to be a promising method for the study of DNA–protein interactions.

Flanking sequence effect

Thomas and Davis[46] established that DNA sequences flanking the recognition site influence the hydrolysis rate by approximately an order of magnitude. These results have been confirmed and extended[47–49]. Two hypotheses (which are not mutually exclusive) can be advanced to explain these data: (1) Contacts occur between the enzyme and DNA bases outside the canonical hexanucleotide; (2) the conformational free energy of the neo-2 kink and/or of the terminal block depends on the flanking base sequence.

We have seen no significant interactions between *Eco*RI endonuclease and bases outside the canonical hexanucleotide. However, we must again emphasize that this cannot be stated unequivocally until all relevant side chains have been located and their positions refined. We do see substantial interactions between the protein and DNA backbone segments which extend beyond the canonical hexanucleotide. These observations are consistent with the latter hypothesis.

This raises the possibility that *Eco*RI endonuclease interacts with DNA in two sequence-dependent ways: (1) A direct specificity interaction with the central hexanucleotide which creates the precise requirement for the *Eco*RI sequence, GAATTC; (2) an indirect interaction with sequence 'selectivity' which subtly modulates the binding energy as a function of base sequence within the regions immediately flanking the *Eco*RI site. Sequence specificity is mediated by physical contact, such as hydrogen bonds, between the protein and DNA bases. Sequence selectivity may be indirectly mediated by sequence-dependent DNA conformational forces.

Conclusions

The following observations include those which we feel are most significant: (1) The direct sequence-specific DNA–protein interactions involve the major groove of the DNA in a tight, complementary interface with *Eco*RI endonuclease; (2) minor groove contacts do not appear to be significant determinants of sequence specificity in this case; (3) the DNA conformation in the recognition complex is a departure from the B-motif; (4) the torsional neo-1 kink is required for the protein to fit into the major groove of the DNA; (5) kinks are now experimentally observed elements of DNA structural heterogeneity which may have a general role in DNA–protein recognition.

We thank Richard Dickerson for steady encouragement and for reading a preliminary version of this manuscript, Keiichi Itakura for training and generous assistance in establishing our own triester synthesis facility, and Lewis Jacobson for suggesting the term neo. This work was supported by NIH grant GM25671.

Reverse stellar evolution, quasars and low-mass X-ray binaries

F. Verbunt, A. C. Fabian & M. J. Rees

Institute of Astronomy, Madingley Road, Cambridge CB3 0HA, UK

Recently, Mathews has proposed[1] a mechanism for the mass supply to a black hole in the centre of a quasar (see also ref. 2). According to this proposal the X rays from the central source penetrate the photosphere surrounding low-mass stars. The absorbed energy is distributed over the stellar interior by convection, and the star expands rapidly. Its outer layers are then stripped by the radiation field of the central source. There are two major uncertainties in this model of reversed evolution; the depth to which the X rays impinging on a low-mass star can penetrate before they are absorbed and the inward transport of the energy flux. The crucial hypothesis of Mathews is that the X rays are absorbed within the convection zone. We now test this hypothesis by considering the effects of X-ray absorption in the secondaries of low-mass X-ray binaries. We conclude that reverse evolution does not occur.

In low-mass X-ray binaries a late dwarf transfers matter by Roche-lobe overflow to a neutron star through an accretion disk[3]. As generally no X-ray eclipses in these systems are observed, it has been concluded that the secondaries are shielded from the X rays of the neutron star by the accretion disk[4]. Optical studies have shown that this shielding is not complete. Orbital variations in the optical, due to X-ray heating of the surface of the secondary facing the neutron star, have been detected in Sco X-1, 4U2129+47 and 4U/MXB1735−44 (ref. 5). In Sco X-1 and 4U1735−44 part of these variations may be due to heating of a bulge in the accretion disk[5]. The recently discovered sharp X-ray eclipses in MXB1659−29 (ref. 6) show that the secondary in this system intercepts X rays from the neutron star. Optical pulses have been detected in 4U1626–67 at a sidelobe frequency to that of the X-ray pulses and shown to arise from X-ray reprocessing on the secondary. The strength of the optical pulses shows that a large fraction of the surface of the secondary facing the neutron star is exposed to the X rays[7]. The importance of these observations for the present discussion is that they show that the secondaries in low-mass X-ray binaries are exposed to X-ray irradiation, and that reverse evolution—if viable—should occur in them. In particular, we note that a main sequence companion star to 4U1626–67 would be $\sim 0.08\ M_\odot$ (ref. 7), and therefore precisely the kind of red dwarf considered by Mathews[1].

We will compare the time scale of the evolution of an X-ray binary undergoing reverse stellar evolution with the Kelvin–Helmholtz time scale of the mass-losing secondary

$$\tau_{KH} = \frac{GM^2}{RL} \simeq 3\times 10^7\ \mathrm{yr}\left(\frac{M_\odot}{M}\right)^2 \qquad (1)$$

Here M and R are the mass and radius of the secondary, respectively. To obtain the last equality we have used the mass–radius and mass–luminosity relations for the main sequence $R \propto M$ and $L \propto M^3$. For fully convective low-mass stars the Kelvin–Helmholtz time scale is of the order of 10^9 yr.

Let us suppose that the X-ray energy flux were transported inwards to heat the interior directly. The star would then adjust its structure on a time scale given by

$$\tau_X = \tau_{KH}\frac{L}{L_a} \qquad (2)$$

where $L_a (\gg L)$ is the absorbed luminosity. A single star in the X-radiation field of a quasar would expand on the time scale given by equation (2), which is much shorter than the Kelvin–Helmholtz time scale. In a low-mass binary the expansion would lead to mass-transfer on the expansion time scale τ_X.

To estimate the relevant time scales we have to determine the amount of absorbed X-ray energy, which in the binary can be written

$$L_a = f\frac{\pi R^2}{4\pi a^2}L_X \simeq \frac{f}{4}\left(\frac{R}{a}\right)^2\frac{L_x}{L_{Edd}}1.8\times 10^{38}\ \mathrm{erg\ s^{-1}} \qquad (3)$$

Here a is the semi-major axis of the binary orbit, L_X is the X-ray luminosity and L_{Edd} is the Eddington luminosity of a $1.4\text{-}M_\odot$ neutron star, equal to $1.8\times 10^{38}\ \mathrm{erg\ s^{-1}}$. f is the product of a correction factor to the rough estimate $(R/a)^2/4$ of the spatial angle subtended by the secondary as seen from the neutron star, the fraction of this spatial angle that is not shielded by the accretion disk, and the fraction of the X rays impinging on the surface that penetrate into the stellar interior. Assuming with Mathews that approximately half of the X-ray flux penetrates deeply, we find typical values for f betweeen a fifth and a tenth. (R/a) is a slowly varying function of the secondary mass, well approximated by[8]

$$\frac{R}{a} \simeq 0.46\left(\frac{M}{M+M_{ns}}\right)^{1/3} \qquad (4)$$

Combining equations (1)–(4) we get

$$\tau_X \simeq \frac{1.3\times 10^4}{f}\ \mathrm{yr}\ \frac{M}{M_\odot}\left(\frac{M+M_{ns}}{M}\right)^{2/3}\frac{L_{Edd}}{L_X} \qquad (5)$$

If reverse evolution could operate, the following would happen in a low-mass X-ray binary. Once the mass transfer starts, the X rays will penetrate into the secondary and cause it to expand. The expansion will increase the mass transfer, and hence cause a higher X-ray luminosity. Thus the mass transfer and the X-ray luminosity grow exponentially, until the Eddington luminosity is reached, or until the mass flow prevents the radiation produced by the accretion process reaching the convection zone of the secondary. After this the evolution proceeds linearly on the time scale given by equation (5), that is shorter than $\sim 10^5$ yr. The initial exponential growth of the mass transfer rate occurs in the time $\tau_x h/R$ needed by the secondary to expand an atmospheric pressure scale-height h outside its Roche lobe. This is within $\sim 10^4$ yr, even for low-luminosity X-ray binaries ($L_x \simeq 10^{36}\ \mathrm{erg\ s^{-1}}$).

The consequences for our Galaxy are then that most low-mass X-ray binaries should be at the Eddington limit, and presumably many of them would show strong absorption effects in the X rays. This is not supported by the observations. Only if the shielding of the secondary by the accretion disk and the scattering of the hard X rays reduces f below $\sim 10^{-4}$ could reverse evolution be compatible with the observations.

In addition, if low-mass binaries were undergoing reverse evolution their average life time would be of the order of 10^5 yr

only. The impossibility of such short life times is particularly clear in globular clusters. The number of bright low-mass X-ray binaries observed in each of the densest globular clusters is of order unity[9]. For an average life time of τ yr this means that a system has to be formed in a typical dense cluster every $1/\tau$ yr. The formation rate[10] as calculated from the number of close encounters between compact remnants and main sequence stars in the cluster is in good agreement with an average life time of the low-mass X-ray binary of $\sim 10^9$ yr, but not with a life time of 10^5 yr.

We note that a secondary in a low-mass X-ray binary receives an X-ray flux $\geqslant 10^4$ times that of a low-mass star in the X-ray radiation field of a quasar. The X-ray flux received by the latter is more comparable with that received by a secondary in a cataclysmic variable. There is no evidence for reverse evolution in cataclysmic variables.

We have offered empirical evidence that reverse evolution does not occur. But we must not overlook the severe theoretical problems with this idea. An intense flux of incident radiation would tend to quench convection in the outer layers; even if free energy were somehow available to maintain the star in a well-mixed (constant entropy) state, thermodynamical arguments would still restrict the efficiency of inward energy transport against the temperature gradient.

We thank Dr P. P. Eggleton for discussions.

The nature of low-frequency cutoffs in the radio emission spectra of pulsars

Yu. P. Ochelkov & V. V. Usov

Space Research Institute, Academy of Sciences USSR, Profsojusnaja 88, 117810 Moscow, USSR

Low-frequency cutoffs were first observed in the radiation spectra of several pulsars about a decade ago[1]. The detailed study of the low-frequency ($\omega \leqslant 100$ MHz) radio emission spectra of more than 50 pulsars[2–7] has shown that practically all pulsars observed have low-frequency cutoffs in their spectra. In most pulsars the spectral cutoffs are an inherent feature of pulsar emission and are obviously associated with the emission mechanism[8]. The most favoured hypothesis at present is that the radio emission of pulsars is a curvature radiation of charged plasma bunches that move, with a Lorentz factor of $\Gamma \cong 10^3$, practically along curved magnetic field lines[9,10]. The kinetic energy of plasma bunches is comparable with the brightness temperature of radio emission measured in energy units. Hence, the reabsorption of the curvature radiation by the radiating plasma bunches themselves may be essential for the formation of the radio emission spectra of pulsars. Here we show that this radiation reabsorption may be responsible for low-frequency cutoffs in the pulsar radio emission spectra.

The curvature radiation of a system of charged ultrarelativistic particles ejected from the polar cap of a pulsar with a dipole magnetic field has been discussed in detail elsewhere[11], taking into account the emission reabsorption by radiating particles. The spectral density of the curvature radiation flux $F(\vartheta_K, \omega)$ was derived for the direction forming an angle ϑ_K with the magnetic axis at a frequency ω. Following ref. 11 we consider the case of a monoenergetic distribution of ejected particles and the power dependence of their density at the pulsar surface on the distance d to the pulsar's magnetic axis:

$$f(\Gamma, \vartheta_0) = K_0 \delta(\Gamma - \Gamma_0)\left(\frac{\lambda}{\vartheta_0}\right)^{\beta} \Theta[\vartheta_0 - \lambda]\Theta[\hat{\vartheta}_0 - \vartheta_0]$$

where $f(\Gamma, \vartheta_0)$ is the distribution function of ejected particles, K_0 and β are constants, $\vartheta_0 = \arcsin(d/R)$ is the angular coordinate of points on the pulsar surface, measured from its magnetic axis, $\Theta[x]$ is the step function equal to unity for $x \geqslant 0$ and to zero for $x < 0$, and $\hat{\vartheta}_0 \simeq (\Omega R/c)^{1/2}$ is the angular radius of the polar cap of the pulsar, separating the open magnetic field lines, along which particles are ejected ($\vartheta_0 < \hat{\vartheta}_0$), from the closed lines, along which no plasma ejection occurs ($\vartheta_0 > \hat{\vartheta}_0$); $\lambda \simeq \hat{\vartheta}_0^2$; Ω is the angular rotation velocity of the pulsar and R is its radius.

The observed average flux of the curvature radiation at the frequency ω is given by

$$\overline{F(\omega)} = \int_0^{2\pi/\Omega} F(\vartheta_K(t), \omega)\frac{\mathrm{d}t}{(2\pi/\Omega)} \qquad (2)$$

where ϑ_K versus t is

$$\cos\vartheta_K = \cos\vartheta_{\Omega B}\cos\vartheta_{\Omega K} + \sin\vartheta_{\Omega B}\sin\vartheta_{\Omega K}\sin\Omega t \qquad (3)$$

$\vartheta_{\Omega B}$ is the angle between the rotation axis and the magnetic axis, and $\vartheta_{\Omega K}$ is the angle between the rotation axis and the direction towards the observer.

By substituting into equation (2) the expression $F(\vartheta_K, \omega)$ given for the respective frequency intervals by (76)–(79) (ref. 11), we may obtain the integral flux $\overline{F(\omega)}$. In a partial case $\vartheta_K^{\min} \equiv |\vartheta_{\Omega B} - \vartheta_{\Omega K}| = 0$, when in the pulsar rotation process the centre of its curvature radiation beam may coincide with the direction towards the observer, the expression for $\overline{F(\omega)}$ is readily integrable.

The curvature radiation spectrum $\overline{F(\omega)}$ as a function of frequency dependence, for $\vartheta_{\Omega B} \sim 1$, $\vartheta_K^{\min} = 0$ and $\beta > 2$, is written as (see Fig. 1):

$$\overline{F(\omega)} \propto \begin{cases} \omega^{-(\beta-2)} & \text{at } \omega_B \ll \omega \leqslant \frac{9}{8}\frac{c}{R}\Gamma_0^3\hat{\vartheta}_0, \\ \omega^{-4(\beta-2)/(6+\beta)} & \text{at } \omega_m \ll \omega \ll \omega_B \\ \omega^{(6\beta-8)/(1+3\beta)} & \text{at } \omega \ll \omega_m, \end{cases} \qquad (4)$$

where

$$\omega_B = \left[\frac{3}{4}\left(\frac{2}{3}\right)^{2/3}\frac{(\beta-2)\,e^2\lambda^{\beta-2}\dot{N}}{mcR^2\Gamma_0}\left(\frac{8}{9}\frac{R}{c}\frac{1}{\Gamma_0^3}\right)^{-\beta}\right]^{1/(2+\beta)} \qquad (5)$$

$$\omega_m = \omega_B\hat{\vartheta}_0^{[16/3(2+\beta)]} \qquad (6)$$

where $\dot{N}$ is the number of particles ejected from a pulsar per unit time.

Both a break in the spectrum at ω_B and its low-frequency cutoff at the frequencies below ω_m result from the curvature radiation reabsorption by radiating particles as such. In the case considered, two characteristic frequencies appear in the radiation spectrum due to the non-uniformity and anisotropy of a curvature radiation source.

In the case of radio emission from pulsars, particles should be regarded as bunches of electron–positron plasma. Then in equations (5) and (6) the charge Q, mass M and the flux of

Table 1 Values of curvature radiation flux as a function of frequency dependence

	$\frac{6\beta-8}{1+3\beta}$	$\frac{4(\beta-2)}{6+\beta}$	$(\beta-2)$	ω_m (MHz)	ω_B (GHz)
$\beta=3$	−1	0.44	1	75	10
$\beta=4$	−1.23	0.8	2	134	8
$\beta=5$	−1.37	1.09	3	197	6.5

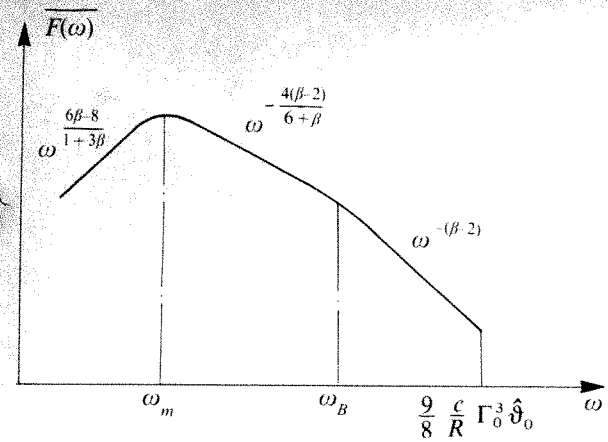

Fig. 1 The curvature radiation spectrum for $\vartheta_{\Omega B}\sim 1$, $\vartheta_K^{\min}=0$ and $\beta>2$.

bunches $\dot{N}_B$ from a pulsar should be used, rather than e, m and $\dot{N}$. The quantities are related as $Q=|n_+-n_-|e=\zeta ne$, $M=nm$ and $\dot{N}_B=\dot{N}/n$, where n_+ and n_- are the number of positrons and electrons in a bunch, respectively; $n=n_++n_-$, $\zeta=|n_+-n_-|/n$ is the degree of charge separation in the bunches of ejected plasma. Substituting Q, M and $\dot{N}_B$ in equations (5) and (6) shows clearly that ω_m and ω_B do not depend on n; there is, however, a relatively weak dependence of ω_m and ω_B on $\zeta(\omega_m, \omega_B\propto\zeta^{2/(2+\beta)})$. If the number of particles n in a bunch is changing, the radiation spectrum (see Fig. 1) shifts along the $\overline{F(\omega)}$ axis ($\overline{F(\omega)}\propto n$ at $\zeta=$constant), although it does not change its shape.

Table 1 summarizes the α values of the curvature radiation flux as a function of frequency dependence ($\overline{F(\omega)}\propto\omega^{-\alpha}$) for different frequency ranges, with β equal to 3, 4 or 5; ω_m and ω_B frequency values are also given for most probable parameters of pulsars[8-10,12]: $\dot{N}=10^{33}$ particles$\times$s^{-1}, $R=1.4\times10^6$ cm, $\Gamma_0=800$, $\hat{\vartheta}_0=10^{-2}$ and with ζ assumed equal to 0.1. In this case, whatever, the value of β, the radiation spectrum extends to the frequency $(9/8)(c/R)\Gamma_0^3\hat{\vartheta}_0$, which is $\sim1.7\times10^{11}$ Hz.

The following are the main observational data about low-frequency cutoffs in the pulsar radio emission spectra (for details see ref. 7). (1) The mean frequency of the pulsar radio emission maximum below which the radio emission flux decreases ($\alpha<0$), is $\omega_m=130\pm80$ MHz. (2) The mean value of the radio emission spectral index in the frequency range below the maximum ($\omega<\omega_m$) is -1.4 ± 0.4. (3) The spectral indices of pulsar radio emission at frequencies higher or lower than the maximum frequency are almost equal in absolute magnitude and opposite in sign, that is, the steeper the radio emission spectrum up to its maximum ($\omega<\omega_m$), the steeper it is after it ($\omega>\omega_m$).

Table 1 shows that when $\beta=4\pm1$ there is a good agreement between the expected behaviour of the curvature radiation spectrum, near its maximum, and the observational data. The ω_m versus β dependence is rather weak.

Above we have considered the case $\vartheta_K^{\min}=0$, when in the pulsar rotation process its magnetic axis may coincide with the direction towards the observer. With the results from ref. 11 it is easily shown that the ω_m frequency value and the curvature radiation spectrum behaviour near the maximum at $\vartheta_K^{\min}\neq0$ do not differ essentially from the case of $\vartheta_K^{\min}=0$ if

$$\vartheta_K^{\min}<\vartheta_r\equiv\frac{8}{9}\frac{R}{c}\frac{\omega_m}{\Gamma_0^3}\hat{\vartheta}_0^{-2} \qquad (7)$$

At $\omega_m=130$ MHz, $R=1.4\times10^6$ cm, $\Gamma_0=800$ and $\hat{\vartheta}_0=10^{-2}$, we have $\vartheta_r\simeq0.1$, that is, the ϑ_r value is sufficiently large ($\vartheta_r\gg\hat{\vartheta}_0$); hence for most pulsars $\vartheta_K^{\min}=0$ may be assumed when the curvature radiation spectrum is considered to be near its maximum.

Note that the model presented here for the generation of pulsar radio emission due to the curvature mechanism may also explain the radio emission spectrum behaviour at higher frequencies (see Fig. 1). Thus, the ω_B frequency (several GHz, see Table 1) falls into the interval of the observed values of the higher-frequency break of the pulsar radio emission spectrum[1,7]. The observed values of the spectral indices after the high-frequency break are ~2 to 3 (refs 1, 7, 8), which corresponds to $(\beta-2)$ for the same values $\beta\simeq4$–5.

Structure, stability and evolution of Saturn's rings

Frank G. Bridges*, A. Hatzes† & D. N. C. Lin†

* Board of Studies in Physics, and † Lick Observatory and Board of Studies in Astronomy and Astrophysics, University of California, Santa Cruz, California 95064, USA

Recent data obtained from the Voyager spacecrafts and ground-based measurements indicate: (1) the rings have a thickness of at most 150 m (ref. 1) and probably several times less[2,3]; (2) the rings are mostly composed of ice particles ranging from centimetres to metres in size[4]; (3) the rings are subdivided into a large number of ringlets with a radial dimension ranging from 10-km down to the several metres resolution of the Voyager spacecraft's camera[5]; (4) the B ring contains very many optical depth variations (0.6–3)[3]. This behaviour is essentially determined by the collisional properties of the rings' ice particles. Here we report some preliminary results from an experiment designed to measure the coefficient of restitution of ice particles colliding at impact velocities relevant to Saturn's rings. We apply these results to simple dynamical models for Saturn's rings and deduce the rings' thickness to be <5 m. We also show that regions with optical depth <0.5, such as the B ring, are unstable to viscous diffusion. Such an instability may be the cause of optical depth variations in the B ring.

The global properties such as the ring thickness and dynamical evolution time scale are basically determined by the collisional dynamics between the ring constituents and the resultant transport processes[6–9]. The cumulative effect of many collisions over a differentially rotating disk, such as Saturn's rings, is to establish a viscous stress which induces an outward transfer of angular momentum, an inward diffusion of mass[10], and an energy transfer from systematic shear into dispersive motion at a rate $\dot{E}_i\approx v\Sigma\Omega^2r^2$, where Ω and Σ are respectively the angular frequency and surface mass density of the disk at radius r. The kinematic viscosity of the disk, is defined by $v\approx\sigma^2/[\Omega(\tau+\tau^{-1})]$ where $\tau=\Sigma A/m$ is the optical depth, A is the cross-section, m the mass of a typical ring particle, and σ is the average amplitude of the velocity dispersion. The particle collisions are partially inelastic and dissipate the kinetic energy associated with dispersive motion at a rate $\dot{E}_d\approx(1-\varepsilon^2)r^2\omega_c\Sigma\sigma^2$ where ε is the coefficient of restitution. The collision frequency, ω_c, is related to Ω such that $\omega_c=\tau\Omega$. A local energy equilibrium is established when $\dot{E}_i=\dot{E}_d$, that is,

$$(1-\varepsilon^2)(1+\tau^2)\approx b \qquad (1)$$

where b is of the order of unity. Assuming that the rings are

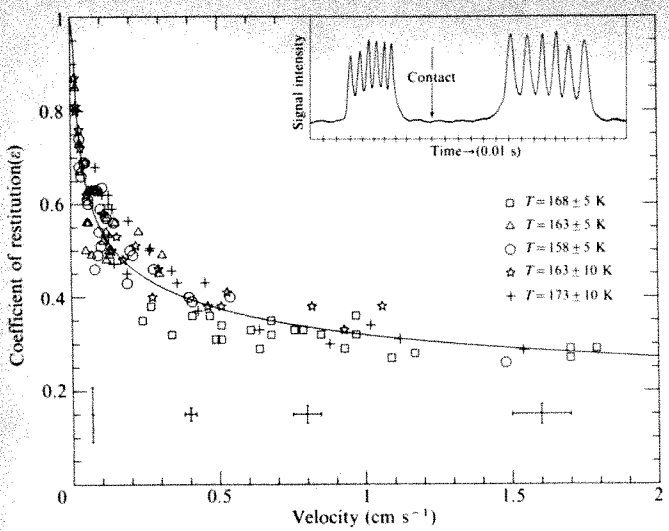

Fig. 1 A plot of the coefficient of restitution as a function of impact velocity for measurements at several different temperatures over the range 158–173 K. Estimates of the typical error bars are shown for four velocities at the bottom. The inset shows two sets of pulses obtained immediately before and after a collision. The values of ε and the velocity are obtained from the spacings of these pulses.

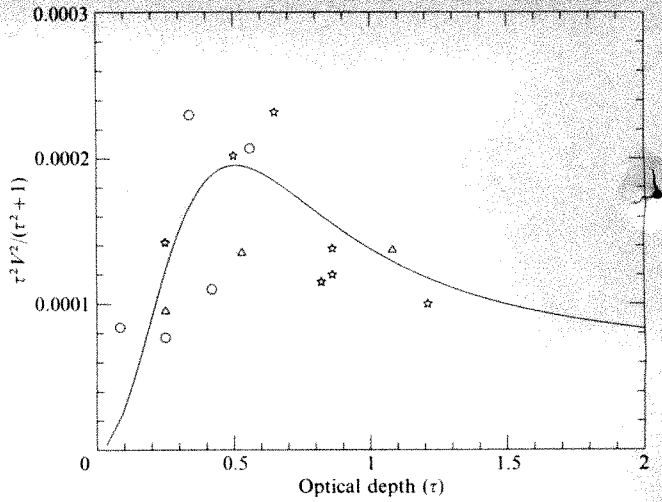

Fig. 2 A plot of $\tau^2V^2/(\tau^2+1)$ as a function of optical depth τ. The values for τ were obtained using equation (1). The points are obtained from the data in Fig. 1 and the solid line is a graph of $\tau^2V^2/(\tau^2+1)$ versus τ according to equation (4).

made of non-rotating, indestructable, and identical size ice spheres with a gaussian phase space distribution, b is determined from the rigorous treatment of the collisional Boltzmann equation[8]. An approximate analytical fit of these results indicates $b \approx 0.61$.

For most solid substances, ε is a function of the impact velocity, V (ref. 11). If an ε–V (or equivalently ε–σ) relationship is available, it can be applied to equation (1) to deduce a τ–σ relationship. If a disk is made up of nearly equally sized particles, its r.m.s. thickness, H, would be $\sim 2f\sigma/\Omega$. Here f is introduced to account for the anisotropy of the velocity dispersion ellipsoid and is of the order of unity ($f \to 1/\sqrt{6}$ as $\tau \to \infty$)[8,12]. Thus, an accurately determined ε–V relationship can be used to deduce H directly.

Another reason for determining an ε–V relation is associated with the viscous stability of disk flow. Several authors[13–15] have suggested that the condition for thermal and viscous stability cannot be satisfied simultaneously if $\tau \gg 1$. In these conditions the rings have a tendency to break up into many ringlets. This mechanism seems to offer a viable explanation for the origin of the density variations in the optically thick B ring where tidal effects due to various saturnian satellites are negligibly small. Physically, if the viscous couple, $W = 3\pi\Omega r^2 \Sigma \nu$, increases with τ, the rings are stable whereas if W decreases with τ the rings are unstable. The W–τ relationship can also be derived from an ε–V relationship. We have designed an experiment and determined this ε–V relationship in a laboratory environment.

To measure ε for ice particles in the conditions assumed to exist in Saturn's rings, the apparatus must meet several criteria. First, the relevant impact velocity must be in the range 0.01–5 cm s^{-1}. Second, the frictional damping of the system must be small compared with the kinetic energy associated with ice particle collisions such that the damping correction factor is relatively small. Third, the relevant ambient temperature should be in the range 100–150 K. Fourth, before and after each collision, the ice particles must be separated by a sufficiently large distance, say >0.01 cm, such that tiny powdered ice chips on their surface do not induce strong interactions between them except during the course of each collision. Finally the collisions should resemble free collisions as closely as possible.

The simplest experimental system which can satisfy most of the above requirements is to attach an ice ball to an oscillator and let it strike a stationary block of ice. A sufficiently low impact velocity and a reasonably large oscillator amplitude can be achieved with a compound pendulum with the axis of rotation very close to the centre of mass. In this case, the angular frequency is $(Mgd/I)^{1/2}$ where M and I are the mass and moment of inertia of the system. We constructed such a system using a disk mounted on an aluminium rod. Small weights at the top and bottom of the disk allow us to adjust the distance between the centre of mass and the suspension (that is rotation) axis, d. An ice ball is attached to one edge of the disk and a counter weight on the other edge in a manner such that their centre of mass is at the centre of the disk. The entire system is suspended by knife blades resting on polished agate plates. With this system, we have achieved periods as long as 60 s with the Q-value equal to 4. For shorter oscillation periods, such as $T < 30$ s, $10 < Q < 30$.

The main limitation of the above system is that collisions are not entirely free. The coupling between the ice particles and the pendulum body will cause a slight elastic deformation in the pendulum during a collision. However, we note that most of the kinetic energy dissipation occurs as a result of fracturing at the tiny contact surface area of the ice particles. For typical impact velocities the time interval during contact is considerably longer than the sound crossing time across the ice balls. Our experiments indicate that a sufficiently rigid mounting of the ice particle onto the pendulum effectively eliminated temporal redistribution of elastic energy within the system and thereby provided a good measure of ε.

The ambient temperature of the system is set at 150–175 K using a simple cryostat constructed from styrofoam and cooled with liquid nitrogen. The ice-block temperature is measured with an Omega thermocouple thermometer frozen into the ice block. The velocity of the ice ball is measured by reflecting a laser beam off a mirror mounted on the rotation axis of the pendulum. The reflected beam passes over a photocell masked with five slits 1 mm wide, 2 mm apart and situated 4 m from the pendulum. The photocell is positioned close to the point which corresponds to contact. Five pulses produced immediately before and after each collision provide an accurate measurement of the incoming and outgoing velocities from which ε can be deduced. Five slits are used primarily to improve the accuracy of the measurement and to eliminate damping contributions associated with the finite Q value of the pendulum. The results of our experiments indicate that only a small, that is <2%, correction is ever needed to account for damping.

A typical pulse train and the summary of the results obtained from the four lowest temperature runs are illustrated in Fig. 1. The general behaviour of ε as a function V is typical of the data taken at other temperature ranges. The data can be qualitatively divided into three cases. At relatively large V, ε changes little over a wide range of impact velocity. Below $V \approx 0.25$ cm^{-1},

ε increases rapidly with decreasing V. The extrapolation of our data indicates that, at a sufficiently small but finite velocity, ε approaches unity. This behaviour at the low velocity limit is consistent with the classical theory of nearly elastic deformation associated with low-velocity impacts[16–18]. However, the asymptotic plateau for relatively large velocity cannot be accounted for by any existing collision model.

The data presented in Fig. 1 can be fitted remarkably well with a power law

$$\varepsilon = (0.32 \pm 0.02)\, V^{-0.234 \pm 0.008} \quad (2)$$

where V is the impact velocity measured in cm s^{-1} for the range $0.015 < V < 5.1$. Extrapolation of this power law indicates that $\varepsilon \to 1$ for $V < V_c = 0.008$ cm s^{-1}. The dispersion of the data, relative to the best fitted curve, is much larger for intermediate collision velocities than for large velocities, where ε attains an asymptotic value of 0.25, and for very small velocities where ε approaches unity. Special care has been taken to eliminate various possible external causes for this large dispersion. A trial experiment for collision between a solid synthetic rubber ball (super ball) and a rigid surface yielded an ε–V relationship with dispersion of order less than one-tenth those found for ice ball-block collisions. Clearly, the scattering of the data is considerably larger than the typical measurement uncertainty which is indicated in Fig. 1. We propose that the large dispersion in the data is real, and is probably associated with compression and random powdering of tiny ice chips on the surface. Irregularities in the shape of the ice chips can lead to considerable variation in the radius of curvature and geometry of the contacting surfaces of the ice ball and block. The tendency for the dispersion to decrease at relatively large impact velocities is probably caused by the surface distortion during a collision being large enough to override any variation in the surface geometry immediately before each collision.

Note that the effective mass involved in a collision is 5.4 times larger than the mass of the ice ball mounted to the pendulum. Because the ice block is held stationary, it has an infinite inertial mass. In any event, as Saturn's rings are composed of ice particles with a large range in size, it is desirable to investigate collisions between particles with various masses and sizes. These investigations are underway and the results will be presented elsewhere.

Despite recent considerable observational and theoretical advances in our understanding of Saturn's rings, the actual physical nature of the constituent particles remains unclear. The rings may either be made of solid particles with relatively smooth surface radius of curvature or particles covered with loose ice chips[19]. The amount of gas and dust inclusions in the ring particles is also unknown. In our experiments, both the ice ball and ice block are prepared with a smooth surface and are relatively free of gas or dust. (The amount of surface frost on the ice ball has also been minimized although this can never be eliminated.) Furthermore our data are obtained for direct collisions whereas grazing collisions may be far more common in Saturn's rings. Thus, it is not entirely clear to what extent the data obtained from the above experiment are relevant to the structure of Saturn's rings. Nonetheless, we apply our results to the standard uniform-size hard sphere model[8] for simplicity. Under this assumption, V_c defines a lower limit on the thickness of the disk which is $\sim V_c/\Omega = 50(V_c/0.01\ \text{cm s}^{-1})(10^{10}\ \text{cm}/r)^{3/2}$ cm. If we apply the results of equation (2) to equation (1), it follows that

$$H = 2f\sigma/\Omega = 80f[1 - b/(1+\tau^2)]^{-2.1}(r/10^{10}\ \text{cm})^{3/2}\ \text{cm} \quad (3)$$

Applying an idealized, uniform-particle sized model, we derive for most regions of the ring that $H < 5$ m, provided the particle size is smaller than H. This value is consistent with that deduced from microwave scattering experiments[2]. The slight difference between these values and those deduced from resonant damping analyses[3] may be due to the additional energy source associated with external perturbers.

In the absence of external stimulation, such as Saturn's satellite resonances, the energy equilibrium implies an effective viscosity

$$Nu \approx 0.3(r/10^{10}\ \text{cm})^{3/2}\frac{[1 - b/(1+\tau^2)]^{-4.2}}{(\tau + \tau^{-1})}\ \text{cm}^2\ \text{s}^{-1} \quad (4)$$

and a corresponding diffusion time $T_d \simeq r^2/\nu$, longer than the age of the Solar System. The corresponding viscous stress is plotted in Fig. 2. Superimposed on the actual data is a W–τ relationship derived from equation (2) such that

$$W \sim [1 - b/(1+\tau^2)]^{-4.2}\tau^2/(1+\tau^2) \quad (5)$$

The maximum value of W is attained at $\tau_c = (1-b)/(4.2b-1)$. The scatter of the original data (Fig. 1) is amplified in Fig. 2 by numerous mathematical transformations of the experimental data. The results in equation (5) imply that, for $\tau \gtrsim 0.5$, W decreases with τ and therefore the rings are unstable. For $\tau \lesssim 0.5$, the rings are stable. If we were to take the widely scattered data points, the critical τ would lie in the range 0.3–0.7. Thus, the optically thick regions of the disk are expected to be diffusionally unstable and would open up low density regions with τ of the order 0.5–0.7. The observed optical depth profile of the B ring indicates that the typical τ in the less opaque regions of the B ring is ~0.6 (ref. 3).

In the above discussion we have not considered the effect of particle size distribution. Note that the large, metre-size particles have radii comparable to or larger than the ring thickness, as derived from equation (3), such that they may form a 'monolayer'. For these particles the velocity dispersion is determined by the gradient of the rings' keplerian velocity across their diameter[7] so that their W monotonically increases with τ and their motion is viscously stable. Consequently, the small centimetre-size particles and the large metre-size particles in the high τ B ring may have rather different radial structure. Voyager's data indicate that the primary contribution to the τ variation in the B ring is from the small particles. The large particles have a relatively smooth radial distribution. Thus, a realistic model for the evolution of the B ring requires a detailed analysis of the collisionally induced transport process for a collection of particles with different sizes (G. Stewart, in preparation). We intend to supplement the experimental data presented here with data on collisions between ice balls with different radii of curvature at the contact point.

The above results may also be applied to study the actual damping process in resonant excited density waves[20,21], the structure of narrow rings and sharp edges as well as the satellite shepherding phenomenon[22]. As for our experiments, variations in ice ball's and ice block's surface geometry, surface crystal lattice structure, collisional grazing angles, and ambient temperature will be examined in future. In general, we believe that the results presented here are a first step towards understanding ice-particle collisional processes.

Topographic EXAFS

§ Present address: Department of Materials Science and Engineering, Northwestern University, Evanston, Illinois 60201, USA

The EXAFS (or extended X-ray absorption fine structure) method of absorption-edge spectroscopy for the determination of crystal bond lengths and coordination number, especially in the first coordination shell, is in very widespread use in chemical, crystallographic, biological and to some extent metallurgical research. The high-resolution method of X-ray diffraction topography, which reveals crystal defects, is likewise widely used in studies on crystal growth, phase transformations, chemical decomposition and mechanical properties and domain studies: that is, in the area of 'microstructure' rather than 'crystal structure'. It is obvious that the techniques are complementary and that both could be required to solve a particular problem—structural changes induced by segregation at a surface or internal interface, for example. However, up to now, EXAFS data have been taken only as an average over large samples, thus losing all microstructural information, and topographic data have not provided structural, bonding or chemical information. We present here the first experimental method of combining these experiments, simultaneously on one specimen.

The method relies on the properties of synchrotron radiation (SR)[1], whose high intensity and continuous spectrum enables EXAFS spectra to be accumulated in reasonable times (some tens of minutes) and X-ray topographs to be taken in some seconds. An obvious way of combining the methods would be to take an X-ray topograph to locate areas of interest, place an aperture of diameter equal to the resolution required in this area and measure successive EXAFS spectra during a linear or raster scan of the area. This method would certainly provide the best spectral data, but a rapid calculation of available intensities shows that with most current SR sources the data collection times would be quite impractical—days or weeks.

A possible way of speeding up the spectral data collection is the use of white radiation incident on the sample, followed by a dispersing element (for example, bent crystal) and a film or linear detector; this has recently been achieved[2,3] and results in dramatic decreases in data collection times. The topographic data can then be collected in a separate exposure.

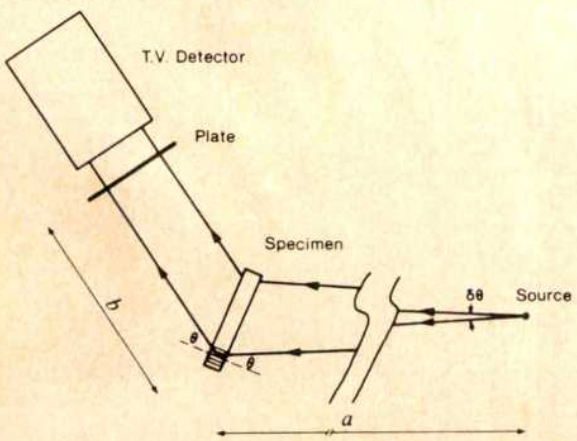

Fig. 1 Experimental arrangement for white beam topography. Typical specimen–source distances, *a*, are 20–80 m and specimen–film distances, *b*, 10–100 mm.

If a good quality single crystal is being used as the specimen, as it often is when topographic information is sought, a further and very simple technique is to use the specimen as its own monochromator. In the white radiation topographic method (Fig. 1), the incident beam diverges from the SR source, which is some tens of metres distant from the specimen. There is therefore a small variation of incident Bragg angle across a specimen, and a consequent variation of wavelength (energy) selected by the specimen for diffraction.

The experimental procedure is as follows. The orientation of the specimen is chosen and set so that the wavelength selected by some part of the specimen is at the absorption edge under

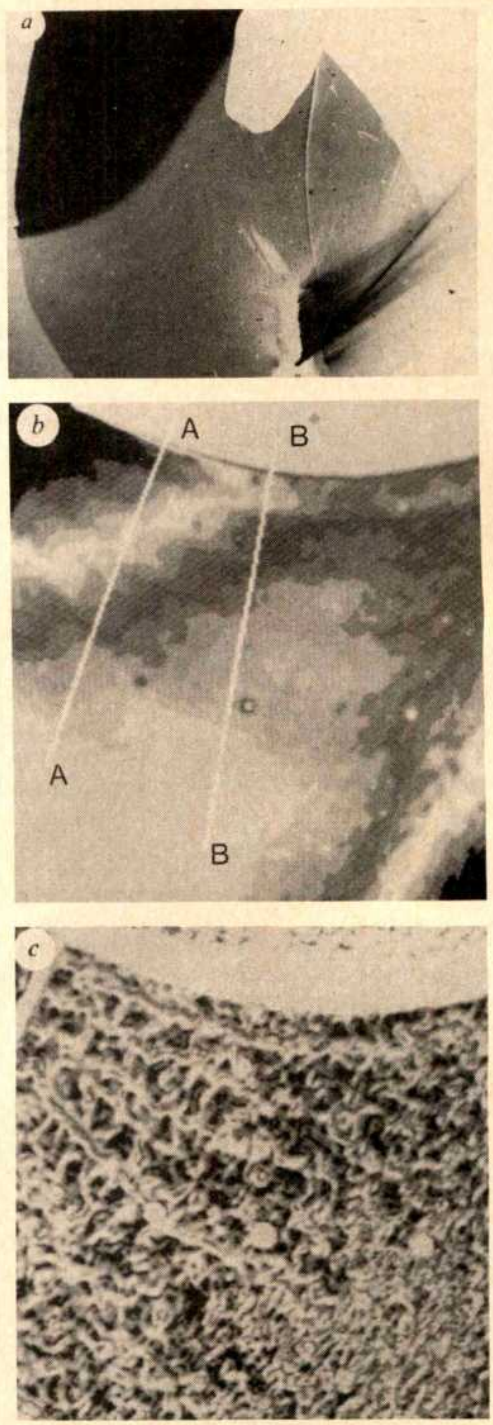

Fig. 2 *a*, White radiation topograph of Nb specimen (near perfect but with some elastic bending). 002 reflection, $\lambda = 0.65298$ Å at the absorption edge. SRS parameters 2 GeV 86 mA, 25 s exposure on Ilford L4 plate. *b*, Digitized and image processed (smoothed, threshold cut and contrast stretch) version of *a*. Image are 2.24 × 2.24 mm. *c*, Differentiated version of *b*.

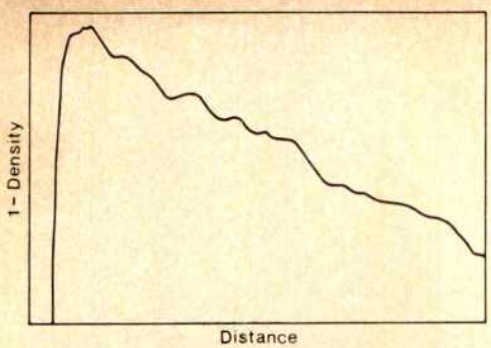

Fig. 3 Density traces extracted from Fig. 2, along line AA.

study. A standard topographic image is then recorded on high resolution plate, for example Ilford nuclear emulsion L4, exposed so that the high absorption side of the image is in good contrast. The wavelength selected by a point on the image is a direct function of the distance on the image from the edge, measured normally to the latter. The diffracted beam falling on each point will therefore have suffered scattering and absorption characteristic of a given photon energy. This results in 'fringes' in the image, parallel to the image of the edge, corresponding to maxima and minima in the EXAFS spectrum.

The first results, taken on the white radiation camera[4] at the SRS, Daresbury Laboratory, are shown in Fig. 2. Figure 2*a* shows the standard topographic image of a 125-μm thick Nb specimen at the Nb $K\alpha$ edge, reproduced photographically. The absorption edge is clear, but the fringes have weak contrast and are not evident. However, image processing techniques can be used to reveal them. The original plate was digitized on a Joyce Loebl flat bed densitometer with 5-μm resolution and the resulting matrix digitally smoothed and processed to cut off low and high values and to stretch the contrast. The result is shown in Fig. 2*b*; Fig. 2*c* shows a differentiated version of Fig. 2*b*. In each of these, especially the latter, the fringes are easily visible. Figure 2 shows density variations along the line marked AA in Fig. 2*b*. These show, albeit noisily, a typical EXAFS spectrum.

To demonstrate that these are indeed EXAFS-type data, comparison was made with an EXAFS spectrum taken on a rotating-anode generator of a 25-μm thick Nb foil. A rotating anode generator with a Mo target and a Si 800 bent crystal monochromator were used. The spectrum in Fig. 3 was calibrated for energy by comparison with the absorption edge positions in a set of topographs in which the specimen was rotated by 0.025° steps between each topograph. A composite photograph of the successive topographs is shown in Fig. 4. This provides an internal calibration that eliminates uncertainties due to curvature of the specimen, though it would not be necessary on a truly flat specimen. The energies corresponding to minima in the EXAFS spectrum are shown in Table 1 for the present results and the standard spectrum. The agreement leaves no doubt that this white-beam method measures true EXAFS data, simultaneously with the topographic image, with an exposure time of 25 s in this case.

Table 1 Comparison of X-ray energy at spectral minima in data extracted from the topograph (Fig. 2*b*) and from a standard EXAFS spectrum

Fringe edge	From topograph (keV)	From spectrum (keV)
	18.99	18.990
1	19.07	19.074
2	19.13	19.124
3	19.19	19.180
4	19.24	19.252
5	19.29	19.330

Estimated errors are ±0.01 keV from the topographic data and ±0.005 keV from the spectral data with the exception of fringe 5 (rather broad) where they are each about ±0.02. The topographic data were calibrated relative to the edge taken as 18.99 keV.

We need to know what is the quality of the EXAFS spectra obtained by this means (the images show normal topographic resolution and contrast). There are several factors to be considered: (1) dispersion and energy range; (2) effect of finite source height; (3) effect of source divergence; (4) wavelength acceptance of crystal reflection; (5) spatial resolution of photographic plate. Let the source height be h, the source–specimen distance a, the specimen–detector distance b, and the Bragg angle θ. ψ_0 and ψ_h are as usual the angles made by the incident and diffracted beams with the inward-facing surface normals and $\gamma_0 = \cos\psi_0$, $\gamma_h = \cos\psi_h$. Examples of the application of the equations will be given for the case corresponding to the

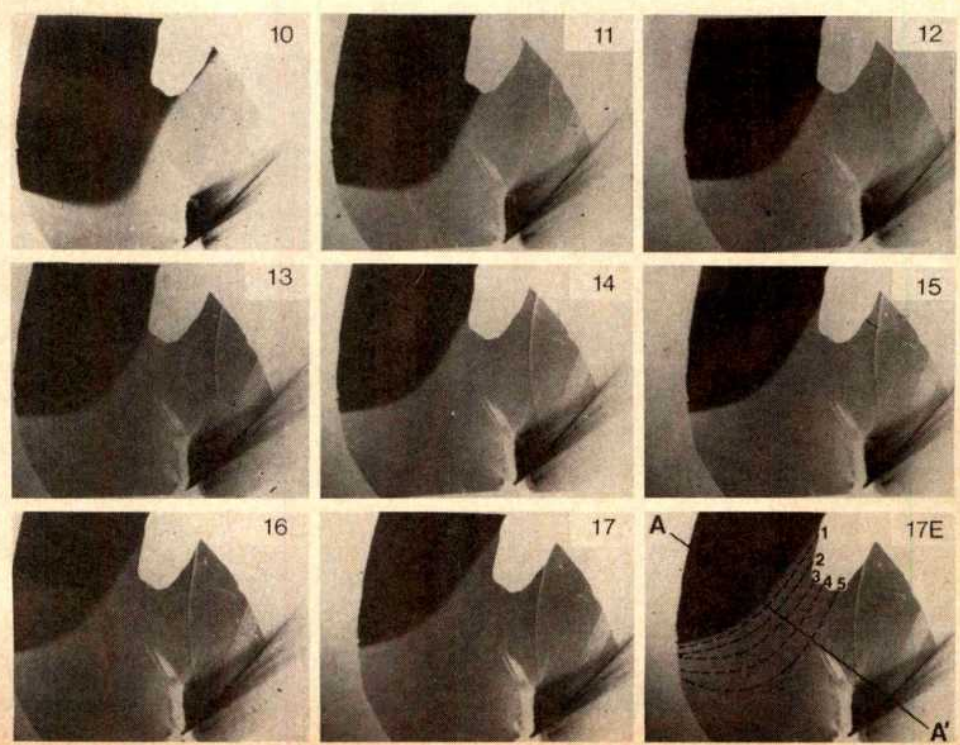

Fig. 4 Composite topograph of area shown in Fig. 2, showing successive positions of absorption edge as specimen rotated in 0.025° steps.

experiment reported above: Nb 002 reflection, $\gamma_0 = \gamma_h = 1$, d-spacing 1.6503 Å, $\theta = 11.4105°$ at the K absorption edge which is at 0.65298 Å, $a = 81$ m, $b = 75$ mm.

The position of a point on the image is defined by its perpendicular distance x to the absorption edge, with the photographic plate set normal to the diffracted beam. Straightforward geometry gives, assuming for the moment a point source, a dispersion relation:

$$\frac{\delta\lambda}{\lambda} = \frac{\gamma_0}{\gamma_h} \cot\theta \frac{x}{a} \quad (1)$$

if b is small, otherwise (because the diffracted rays converge from the specimen)

$$\frac{\delta\lambda}{\lambda} = \cot\theta \frac{x}{a\frac{\gamma_h}{\gamma_0} - b} \quad (2)$$

For the Nb example this gives a wavelength or energy dispersion of 3.06×10^{-7} per 5 μm digitizing element. Over a 10-mm image, the range is thus 6.12×10^{-4}. These figures correspond to 0.0058 eV resolution and 11.6 eV range. This spectral resolution cannot be achieved in practice for various reasons, discussed below, but the range in the Nb sample discussed above was ~300 eV over 2 mm (from internal calibration), therefore the specimen was curved with ~0.63 m radius of curvature. One purpose of recording the absorption edge position as a function of inclination was to determine this curvature, near a notch in the specimen. The dispersion range is thus adequate for XANES (X-ray absorption near-edge structure) measurements on a flat specimen, but for a full EXAFS spectrum several topographs should be taken at different inclinations. Most SR beam lines are much shorter than 80 m and so greater energy spread would occur.

The finite source height (in the incidence plane) has a great effect on the resolution. Imagine a parallel beam the height of the source falling on the specimen. This will be diffracted to a beam the same height (multiplied by the asymmetry factor γ_h/γ_0) and be recorded on the film, blurring spectral data in this region. The minimum useful area on the film is therefore $h\gamma_h/\gamma_0 = x_{min}$. This can be combined with the dispersion equation (1) to give the minimum spectral resolution

$$\frac{\delta\lambda}{\lambda_{min}} = \frac{h \cot\theta}{a} \quad (3)$$

(with a corresponding equation if equation (2) is used). For the niobium example with the SRS FWHM value of $h = 300$ μm, we obtain for the Nb example

$$\frac{\delta\lambda}{\lambda_{min}} = \frac{\delta E}{E_{min}} = 1.84 \times 10^{-5} \text{ or } 0.35 \text{ eV}$$

If now x is taken to be $h\ \gamma_0/\gamma_0$ then the apparent source divergence is $2h/a$. For the SRS at $a = 81$ m, this results in

$$\frac{\delta\lambda}{\lambda} = \cot\theta\ 7.4 \times 10^{-6} \quad (4)$$

For Nb_{002}, this becomes 3.7×10^{-5}, ~0.7 eV.

The effect of the wavelength acceptance of the crystal is found from the FWHM of the rocking curve as $\delta\theta$, using $\delta\lambda = \cot\theta\delta\theta$. For an appropriate FWHM ~5 arc s, this gives

$$\delta\lambda = 1.72 \times 10^{-4} \text{ or } 3.25 \text{ eV}$$

The effect of the spatial resolution of the plate ≲1 μm, is quite negligible on the spectral resolution ($\delta\lambda/\lambda \sim 10^{-7}$), because the intrinsic dispersion is so high.

Combining these three effects (source height, divergence and wavelength spread) by taking the root of the sum of the squares leads to an energy resolution in the Nb case of 1.3×10^{-4} or ~3.4 eV. This is perfectly acceptable for the purpose. The dominant factor is the wavelength acceptance of the crystal, and this could easily be decreased by using a weaker reflection.

The signal-to-noise ratio on the spectrum in Fig. 3 is poor and not normally acceptable for a useful EXAFS spectrum: note that the specimen was about five times thicker than the ideal. However, only 4 pixels were involved in each smoothing operation, giving 20 μm spatial resolution, whereas the minimum useful pixel size is $h\gamma_h/\gamma_0 = 300$ μm in this case. Because nuclear emulsion can record up to about 5 photons μm^{-2} at this wavelength, smoothing over a 300-μm range would give a dynamic range of $5 \times 300^2 = 4.5 \times 10^5$ and a corresponding precision of 0.15%. Whilst this is still not as good as the best EXAFS experiments it is acceptable for many purposes.

What then are the applications of this technique? Whilst it is a rapid and convenient way of obtaining EXAFS spectra if good crystals are available, often they are not, at least without considerable effort. The interest must lie in the ability to perform chemical and defect crystallography on the same sample, as can be performed (on very different samples) by the electron energy loss method[5]. Applications such as structural changes near interfaces with segregation or at decorated dislocations, valence state changes in defect ionic compounds (for example, iron salts, some of which are important catalysts), structural changes at the onset of chemical decomposition are possible. Whilst in principle one could scan the specimen in orientation to reconstruct the complete spectrum for each pixel on the image this would probably not be necessary in practice. A structural or chemical change at a pixel, from sufficient volume of the specimen, would result in a distortion of either the position or the intensity of the local fringe pattern. This would often provide the clue to anomalous behaviour, which could be followed up with techniques such as microbeam EXAFS over a small, closely defined area, or microbeam trace element analysis, all using the same apparatus.

It is also apparent that similar contrast is to be expected in radiographs taken near absorption edges with non-dispersive monochromators. With brighter and more intense sources, TV detectors and image processors, dynamic topographic EXAFS should be a real possibility.

We thank Professor A. J. Forty (University of Warwick) who first encouraged us to look for techniques of microbeam EXAFS, and Dr P. Georgopoulos (Northwestern University) for help in obtaining the reference Nb EXAFS spectrum, and Daresbury Laboratory staff for cooperation and the SRS facilities. The work was carried out with the support of the UK SERC (grant GR/B61283 and the US ONR (contract N00014-C-1012).

Natural chlorine isotope variations

Ronald Kaufmann*, Austin Long*, Harold Bentley† & Stanley Davis†

*Department of Geosciences, and †Department of Hydrology, University of Arizona, Tucson, Arizona 85721, USA

Previously known natural variations in the stable isotope ratio of chlorine, $^{37}Cl/^{35}Cl$, have been within the experimental error of ±1.0‰. [All our measurements are reported in terms of δ^{37} in units of ‰; $\delta^{37}Cl = |(Rx/Rs) - 1| \times 1{,}000$, where $R = {}^{37}Cl/{}^{35}Cl$.] Using methyl chloride gas in a ratio mass spectrometer, we have increased the precision of measurement to ±0.24%, and report here significant isotope variation in natural chlorides. In general, salt deposits and saline hydrothermal springs tend to be enriched in ^{37}Cl with respect to seawater. Groundwater shows both enrichment and depletion with respect to seawater. Saline groundwater becomes more enriched in ^{37}Cl with increasing depth.

Eighty years of chlorine isotope studies[1-9] have shown that the stable isotope ratio, $^{37}Cl/^{35}Cl$, is remarkably constant in nature. Hoering and Parker[7] used HCl gas in a mass spectrometer to measure stable chlorine isotope ratios in 81 samples of natural materials; they found no significant variation beyond their stated limit of 1.0‰, although they did report two samples, both from a deep aquifer brine, as being possibly fractionated. Rankama[10] summarized the bulk of chlorine isotope studies when he wrote, "[Past work] suggests that additional accurate measurements of the isotopic constitution of chlorine in carefully selected samples are required to investigate the possible natural fractionation of the chlorine isotopes". We have used a technique of measurement which is more precise than those used in previous studies, and focused on comparing subsurface brines with seawater and other natural chlorides.

The measurements reported here were made by mass spectrometry of methyl chloride ions (CH_3Cl^+), using the method of Taylor and Grimsrud[11] to prepare methyl chloride gas. Chlorine is quantitatively precipitated as silver chloride (AgCl) from aqueous solutions with silver nitrate. AgCl is then reacted with methyl iodide for 2 days in a reaction vessel at 70–100 °C. The product, CH_3Cl, is then separated from excess methyl iodide by gas chromatography and yields measured to ensure that all of the chlorine is recovered. An isotope ratio mass spectrometer (V. G. Micromass 602C) compared sample CH_3Cl with a commercially-produced reference gas to a precision of ±0.03‰. The total analytical standard deviation, determined from more than 20 replicates of our laboratory standard NaCl over a 1-yr period, is ±0.24‰. Following Taylor and Grimsrud's example, this standard deviation of 0.24‰ is used as the precision for the measurement technique. The mass spectrometer collector slit width masks all but the $m/e = 52$ peak for the minor beam and the $m/e = 50 + 51$ for the major beam. Variations of $^{13}C/^{12}C$ and D/H are minimized by using the same batch of methyl iodide and repeated standardization. Fragmentation patterns should be the same for equally pure sample and reference methyl chloride on a given day's run, and in practice seem not to vary significantly even with filament changes. Frequent monitoring of the constancy of the $51/(49 + 50)$ difference between reference and sample ensures the validity of the data.

Repeated measurements of eight oceanic chloride samples, one from the Gulf of Mexico off the coast of Texas and the others from depths up to 600 m in the Pacific Ocean, gave a total spread of 0.12‰ and a standard deviation of 0.05‰. Results reported here are relative to this standard mean oceanic chloride (SMOC) isotope ratio ($^{37}Cl/^{35}Cl_{oceans} \simeq 0.324$), thus the average $\delta^{37}Cl$ for ocean water is set at 0.00‰.

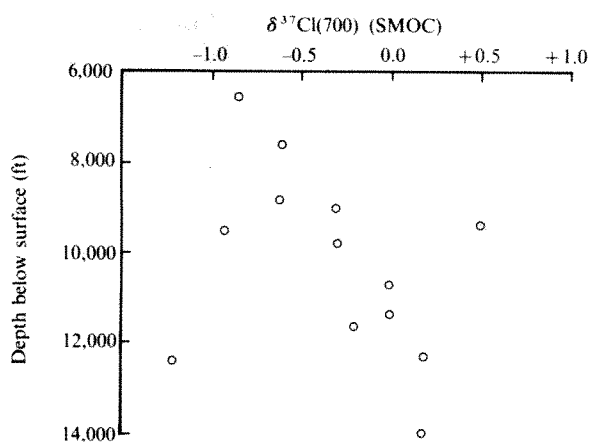

Fig. 1 Variation of $\delta^{37}Cl$ with depth of sample collection in oil field brines from east Texas and Louisiana. The Pearson product moment correlation coefficient for these data is +0.61 and is significant to within the 95% confidence limit[14,15]. Excursions from the apparent linear trend may represent vertical mixing of brines through geological heterogeneities and cracks in well casings. The correlation of ^{37}Cl enrichment with depth may reflect an isotope fractionation mechanism related to the electrostatic properties of subsurface clays (ref. 13 and F. Phillips and H.B., in preparation).

Table 1 shows the results of several groups of samples that we have analysed. Chlorine isotope ratios of aquifer brines from east Texas and Louisiana, including those shown in Table 1, are plotted in Fig. 1 as a function of approximate depth of sample collection.

Table 1 indicates that significant chlorine variation in natural environments does occur, although most of the variation is within 1.0‰ of ocean water chlorine. The range of variation shown is ~2.1‰ with a precision of 0.24‰. Although little can be said about the variations in terms of mechanisms of fractionation, the measurements indicate some distinct geochemical tendencies. Salt deposits tend to be enriched in ^{37}Cl with respect to seawater, as do hydrothermal samples. Groundwater samples may be either enriched or depleted in ^{37}Cl with respect to seawater. The two shallow groundwater samples shown in Table 1 are from the same aquifer, suggesting that within one aquifer there may be more than one chloride source and/or isotope fractionation mechanism. In brines from deep aquifers, increasing isotope enrichment seems to correlate with increasing depth (Fig. 1). Total chloride concentration of these brines also correlates with isotope composition within each aquifer.

To date, all of the samples measured in our study contain chlorine as chloride ions which limits the likely mechanisms for enriching isotopes to precipitation and diffusion processes. $Na^{37}Cl$ may precipitate more readily than $Na^{35}Cl$ just as $^{34}SO_4$ precipitates more readily than $^{32}SO_4$ during gypsum formation[12]. Measurements on NaCl deposits in Table 1 may reflect isotope fractionation during formation. Counter-current electromigration, a laboratory method used to separate chlorine isotopes[13], may be analogous to chlorine isotope fractionation in groundwater (F. Phillips and H. B., in preparation). During counter-current electromigration experiments, chloride in a NaCl solution is driven through a sand-packed tube by an electrostatic force against the convective movement of the solution. ^{35}Cl

Table 1 Results of analyses

	$\delta^{37}Cl$ (‰)*	Student's *t*-test results (probability of variance from SMOC[14,15])
Ocean water samples		
(14 measurements on eight samples, s.d. 0.05‰)	0.00	—
Halite samples

81-1124, Texas	−1.29	>0.99

* All data reported with respect to SMOC.

diffuses more effectively than ^{37}Cl towards the cathode end of the tube. In a groundwater analogue of counter-current electromigration, the electrostatic force may be provided by charged clay mineral surfaces and streaming potential produced by forced convection of water. The convective movement is induced by natural hydraulic and osmotic pressure gradients. Although discussions of fractionation mechanisms based on our results are speculative, experiments and the construction of theoretical models designed to clarify the nature of possible mechanisms are underway.

We thank the following for providing samples for study: W. Kaiser, Texas Bureau of Economic Geology; A. Truesdell, US Geological Survey, Menlo Park, California; T. Casadevall, US Geological Survey, Vancouver, Washington; J. Fabryka-Martin, University of Arizona. This work was supported in part by US Nuclear Regulatory Commission contract NRC-04-78-272.

Suboxic diagenesis in banded iron formations

James C. G. Walker

Space Physics Research Laboratory, Department of Atmospheric and Oceanic Science, The University of Michigan, Ann Arbor, Michigan 48109, USA

Anomalous isotopic composition has been reported for the carbon in carbonate minerals of banded iron formations. Well studied examples show an enrichment in the light isotope of carbon, ^{12}C. This enrichment presumably reflects unusual circumstances in the deposition of these sedimentary rocks. It is suggested here that the isotopically-light carbonate results from early diagenetic oxidation by bacteria of substantial amounts of isotopically light organic carbon. The electron acceptor that permits oxidation in the absence of free oxygen is presumed to be iron(III) which may have been significantly more abundant in the initial chemical precipitate than in the post-diagenetic sedimentary rock.

Banded iron formations are chemical sediments, formed by precipitation of dissolved species from solution[1]. They are composed principally of cryptocrystalline or crystalline quartz, iron oxides (haematite and magnetite), iron silicates (greenalite and related minerals) and iron carbonates (siderite and ankerite)[2]. Banded iron formations are major sources of iron ore. Essentially all of them were deposited before $\sim 1.7 \times 10^9$ yr ago[3], an observation that has been interpreted to reflect a transition at about this time from a hydrosphere devoid of oxygen to a hydrosphere rich in oxygen[4,5]. Because oxidized iron(III) is almost insoluble in all but very acid solutions, the transport of iron in solution and its subsequent chemical precipitation in banded iron formations must have occurred in anoxic waters. The extensive area of some banded iron formations and substantial rates of accumulation of iron and silica seem to imply deposition in basins that were open to the ocean[6–9].

The isotopic composition of the carbonate minerals in banded iron formations has been studied most thoroughly in formations of the Hamersley Basin of Western Australia[9,10]. These undeformed sedimentary rocks have been subjected to only low-grade metamorphism[11]; they date from $\sim 2.5 \times 10^9$ yr ago[12] and appear to have been deposited on a submarine platform or bank protruding into or marginal to an ocean[9]. Carbonate minerals are fairly abundant, typically making up between one-tenth and one-half of the rock[10,13]. Becker and Clayton[14] studied the isotopic composition of the carbonate minerals in the Dales Gorge Member of the Brockman iron formation and reported an enrichment in the light isotope of carbon. Expressed as the departure of the ratio of carbon isotopes from the ratio in a standard carbonate, this departure amounted to an average of $\sim 10‰$, expressed as $\delta^{13}C = -10‰$. This finding has been confirmed and extended by Baur *et al.*[10], who studied the underlying Marra Mamba and Mt Sylvia formations as well as the Dales Gorge Member of the Brockman iron formation. These authors found variable isotopic compositions, but in all cases the carbonate minerals were strongly enriched in the light isotope of carbon. Similar results for banded iron formations in North America have been reported[15,16].

Little isotopic fractionation with respect to dissolved carbonate results from the precipitation of carbonate minerals including the iron carbonates, siderite and ankerite[17], so most marine carbonates have isotopic compositions close to the standard, $\delta^{13}C \sim 0‰$. Indeed, isotope measurements on marine carbonate rocks of different ages are used to infer the history of the carbon isotopic composition of seawater. Such studies have revealed only minor variation of seawater carbon from a value near $\delta^{13}C = 0‰$ since at least 3.5×10^9 yr ago[18–20]. There is no reason to suppose that the isotopic composition of the ocean was any different at the time of deposition of the banded iron formations of the Hamersley Basin. Indeed, the Wittenoom Dolomite[10,14], a non-iron formation carbonate rock immediately overlying the Marra Mamba iron formation, has a carbon isotopic composition of $\delta^{13}C = 0.36‰$ very close to the marine carbonate standard. It does seem likely, therefore, that the carbonate minerals in the iron formations were deposited with isotopic compositions different from that of the seawater from which these minerals were ultimately derived.

Isotopically-light marine carbonate in Phanerozoic sedimentary rocks would generally be attributed to the oxidation of reduced organic carbon during early diagenesis[21]. Reduced organic carbon is strongly enriched in the light isotope, $\delta^{13}C = -25‰$ or lower[22,23]. Diagenetic oxidation of organic carbon in young sediments can dilute the seawater carbonate dissolved in the pore waters of the sediments, yielding isotopically light dissolved carbonate[24]. The carbonate minerals that equilibrate with these pore waters can also be isotopically light. Data on isotopically light marine carbonates of Mesozoic age, presumably produced in this way, have been presented by Irwin *et al.*[21]. Could this process not also have been responsible for the isotopically light carbonates in banded iron formations, a possibility suggested by Baur *et al.*[10]?

The problem with this mechanism is to identify the electron acceptor that made possible the oxidation of organic carbon in iron formations. The assemblage of minerals in these formations provides clear evidence for a very low oxygen fugacity in the pore waters of the sediment[2]. This conclusion is not contradicted by the presence of some iron(III), which is stable even at low oxygen fugacities. So the electron acceptor was not oxygen. There is also no reason to suppose that dissolved nitrate was abundant on the anoxic Earth[25]. But the oxidation process evidently did not involve the reduction of dissolved sulphate to sulphide, because sulphide minerals are not abundant in the iron formations of the Hamersley Basin[3]. Data[26] on the Dales Gorge Member of the Brockman iron formation reveal maximum concentrations of ~ 0.3 wt% and average concentrations much lower. Iron sulphides are relatively insoluble, and any sulphide produced in the sediments by diagenesis would have been precipitated by reaction with the abundant dissolved iron[27,28]. The apparently minor role of sulphate reduction may have been a consequence of low sulphate concentrations in the

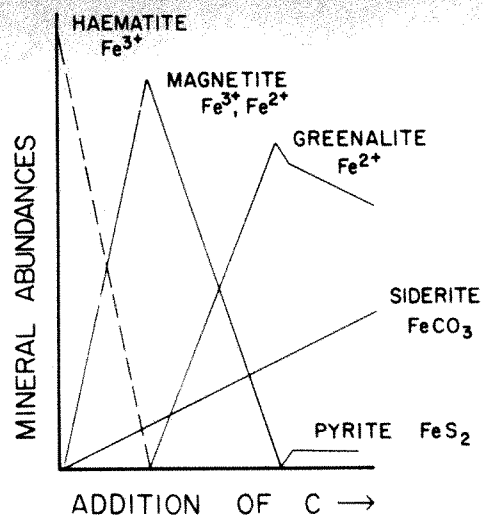

Fig. 1 Suboxic diagenesis of increasing amounts of reduced organic carbon causes the progressive reduction of iron(III) to iron(II). The result is that haematite is replaced by magnetite which is in turn replaced by greenalite and related silicate minerals that contain little or no iron(III). Sulphate reduction and the precipitation of pyrite do not commence until all iron(III) has been reduced. The carbonate produced by diagenetic oxidation of organic carbon precipitates as iron carbonate minerals, siderite and ankerite. The oxide, silicate, and sulphide facies of banded iron formations may reflect increasing amounts of organic carbon in the original sediments.

Archaean and early Proterozoic ocean[29–31]. In recent sediments, when sulphate is exhausted, further diagenetic oxidation of organic matter uses organic matter as the electron acceptor. The metabolic processes are fermentation and methanogenesis. Methanogenesis, however, produces isotopically very light methane and isotopically heavy carbonate[24]. This process could not, therefore, be the source of the isotopically-light carbonates in the banded iron formations. (For a contrary opinion see ref. 10.)

It has recently become clear, however, that iron(III) can serve as electron acceptor in the early diagenetic, bacterial oxidation of organic carbon (see refs 28, 32–34). There is good evidence that particulate iron(III) is reduced to dissolved iron(II) during the anaerobic oxidation by bacteria of reduced organic carbon. The reduction of iron occurs after dissolved oxygen and nitrate have been exhausted and after the reduction of oxidized manganese, but before the reduction of sulphate[32]. Banded iron formations are, of course, rich in iron. Iron(III) could well have been the electron acceptor that permitted diagenetic oxidation of isotopically-light organic carbon by bacteria to produce the isotopically-light carbonate minerals in iron formations[10,15]. A stoichiometrically equivalent reaction was proposed by Perry *et al.* as an abiological, metamorphic process.

The initial oxidation of dissolved iron(II) to particulate iron(III) would have occurred in the water column, possibly near the surface. There are several oxidation processes that would not have required significant concentrations of free oxygen. Abiotic photochemical oxidation has been suggested and investigated experimentally[35,36]. Iron(II) may have served as electron donor in a metabolic process of bacterial photosynthesis[37]. Alternatively, the electron donor for biological photosynthesis may have been water, with the oxygen produced in the process consumed immediately by reaction with excess dissolved iron[4].

Consider an iron formation that contains 5 wt% of CO_2 in the form of carbonate minerals[26]. Suppose that this carbon has an isotopic composition of $\delta^{13}C = -10‰$, which represents a mixture of equal parts of oceanic carbonate with $\delta^{13}C = 0‰$ and diagenetic carbonate produced by the oxidation of organic matter with $\delta^{13}C = -20‰$. The oxidation of 0.7 g of organic carbon per 100 g of rock is required. This would not represent an unreasonably large concentration of organic carbon in the initial sediment.

Oxidation of this carbon according to the stoichiometric relationship

$$C + 2\,Fe_2O_3 \rightarrow CO_2 + 4\,FeO$$

would produce 16 g of FeO per 100 g of rock. Iron formations, including those of the Hamersley Basin, typically contain from 20 to 25 wt% of FeO by weight[3]. The proposed role for early diagenetic oxidation of reduced organic carbon by iron(III) is therefore not contradicted by data on the iron(II) content of banded iron formations.

On the other hand, if 0.7 g of organic carbon were oxidized according to the stoichiometric relationship

$$2C + H_2SO_4 \rightarrow 2CO_2 + H_2S$$

the yield would be 0.9 g S per 100 g of rock. The average sulphide concentration of banded iron formations, including those of the Hamersley Basin, is substantially less than this[3,26].

What are the implications of an early diagenetic source for much of the carbonate in banded iron formations, a source involving the oxidation of reduced organic carbon and the reduction of oxidized iron(III)? First, because this early diagenetic process is a consequence of the metabolic activities of bacteria, the isotopically light carbonate in banded iron formations may be evidence for the presence of bacteria in the sediments that became banded iron formations[38]. Microfossils have not yet been discovered in the banded iron formations of the Hamersley Basin[38]. The calculations presented above suggest that a large fraction of the total iron(II) in these formations may have been reduced by bacteria during early diagenesis. The initial deposits, in this view, contained iron largely in the iron(III) form together with reduced organic carbon in an amount that was stoichiometrically comparable. The preserved ratio of iron(III) to total iron in these sediments is therefore not primary, but is a product of early diagenesis. Also, the generally low concentration of organic carbon in banded iron formations[3] is explained as a consequence of the early diagenetic oxidation of an initially much larger amount of carbon by the oxidized iron of the formations themselves. Finally, the oxide, silicate, and sulphide facies of iron formations[2,39] may reflect a response of the sedimentary system to the early diagenetic alteration of progressively larger amounts of reduced organic carbon (Fig. 1). The oxide facies contains both iron(II) and (III), the silicate facies contains principally the iron(II) form, and the sulphide facies contains iron(II) and sulphide that is presumably the product of bacterial sulphate reduction.

I thank C. Klein and J. M. Hayes for stimulating and informative discussions. R. M. Garrels, J. Veizer, G. E. Claypool, and M. R. Walter offered helpful suggestions. This paper describes research supported in part by NASA under grant NAGW-176 to the University of Michigan. It is a contribution of The Precambrian Paleobiology Research Group.

33,000-yr old chert mining site and related *Homo* in the Egyptian Nile Valley

P. M. Vermeersch, E. Paulissen, G. Gijselings, M. Otte, A. Thoma, P. van Peer & R. Lauwers

Belgian Middle Egypt Prehistoric Project, c/o Laboratorium voor Prehistorie, Katholieke Universiteit te Leuven, Belgium

The Nazlet Khater 4 site (Nile Valley, Upper Egypt) is located on one of the small wadi-interfluves in the lower desert near the steep cliffs bordering the western Nile Valley edge (Fig. 1). We have previously reported[1] the excavation of an early Upper Palaeolithic blade industry at this site, although blade industries in the Nile Valley had only been known[2] to occur since 18,000 yr ago. The 1982 excavation reported here confirms that Nazlet Khater 4 is a chert mining site with a complex extraction strategy, going back 33,000 yr. A nearby grave contained a skeleton of a man in the extended position. We show that the cranial morphology is anatomically modern with archaic characteristics such as a very robust mandible. There is evidence that the skeleton has a similar age to that of the mining site.

The 1982 excavation enabled us to distinguish three sedimentary units: (1) the substratum of the site or the pre-Upper Palaeolithic natural deposits, (2) Upper Palaeolithic diggings in the substratum and their related infills, and (3) later deposits on the site.

The basement of the site consists of greenish silts and fine sands covered by a 1.5-m thick Nile channel deposit, composed of channel lag deposits of well-rounded Nile gravels and chert cobbles and of brown granuliferous silts, covered by a wadi deposit of local limestone gravels (Fig. 2).

Three Upper Palaeolithic digging activities can be distinguished (Figs 1, 2). (1) A trench, 9×2 m, with a depth of 1.5 m had been opened at the northern edge of the Nile deposit, just beyond the covering wadi deposit. All the Nile deposits had been removed from this trench which represents $\sim 15\ m^3$ of ground. (2) Vertical shafts, dug down to the channel lag gravel, had sometimes been enlarged at their base to form bell pits. (3) From the walls of the trench or from the bell pits, the channel lag gravels had been extracted from the substratum for several metres, creating short galleries.

The deposits in the trench and in the bell pits consist of two lithological units: gravels at the base, covered by yellow fine aeolian sand. The gravel unit is a purely gravitational deposit, composed mainly of Nile pebbles, mixed with coarse sands, silts, local limestones, Upper Palaeolithic artefacts, and a fragment of gazelle horn core. Several hearths *in situ* with an abundance of charcoal were observed. This gravel unit is heavily encrusted by a 10-cm thick calcrete on its surface. The top of this unit forms a depression and represents an occupation floor with a large hearth.

The overlying infilling of loose aeolian sands completely hides all Upper Palaeolithic diggings. In the trench, three very slightly encrusted layers with gravels and derived artefacts are intercalated[1]. During the formation of this unit, important deflation and sand accumulation, not found in the gravel layers, took place. The presence of an *in situ* hearth in this sand unit indicates that the site was occupied during this stage. The post-occupation evolution of the site consists of the formation of a salt crust with desiccation wedges and in the flattening out and re-installation of the overall perfect gently eastward dipping slope.

We have currently nine ^{14}C dates at our disposal (Fig. 2). Samples GrN-11297, GrN-11300, Lv-1139D, GrN-11301 and GrN-11299 are from different hearths; samples Lv-1142D, Lv-1141D, Lv-1140 and GrN-11296 are from dispersed charcoal. All dates, ranging from 35,100 to 30,360 yr BP, confirm the great age of the mining site. Statistical tests on different combinations of these samples indicate that they do not belong to the same population (significance level better than 99%), so that it is inappropriate to calculate a mean age for the site. It seems justifiable, however, to classify the ^{14}C dates from the trench according to their lithological positions. The weighted average for the three samples in the gravel unit is $33,470 \pm 360$ yr BP, and for the three samples in the sand unit, $31,980 \pm 650$ yr BP. As their significance level is 5%, we suggest that the mining activities were spread over a period of time which can be determined by ^{14}C dating.

Large quantities of lithic artefacts were recovered. The raw materials are the chert cobbles from the Nile channel lag deposits. Flat elongated chert cobbles were chosen. Flaking of short but regular blades was performed by direct blows with a soft hammer. The butts are flat or punctiform, the bulbs are thin; the Levallois technique was not used.

Tools are rare and are made from flakes or blades by flat retouching, sometimes bifacial, or by oblique retouching. Denticulates aré the best represented tools although some burins and end-scrapers are present. Some bifacial axes have been collected; these are flat, made from flakes or blocks, with concave sides and a convex cutting edge (Fig. 3*a*, *b*).

The Upper Palaeolithic trenches in the substratum were clearly intended for the extraction of chert cobbles which were subsequently used for flaking. The method of exploitation consisted of undercutting the brown granuliferous silts so that the chert cobbles could be extracted, leaving galleries. This technique mainly took place from the trench. The trench was probably the result of an earlier 'trenching exploitation'[3] of the cobble-bearing layer. On the other hand, the trench may have been the result of cleaning after merging different bell pits. It was during the search for the chert cobble-bearing layer, that the bell pits were dug.

The rubble from the trench was dumped on the northeastern edge of the site probably where the chert cobble layer was naturally exposed. We believe that this natural exposure was the reason why the exploitation started.

Such extractions of mineral substances can be considered as real mining[3]. That this was not continuous mining can be deduced from the fact that prehistoric man was not always sure where to start his digging activities: a shaft was lowered into the rubble from earlier extractions and a search for exploitable chert was carried out in the neighbourhood of the site, such as the site of Nazlet Khater 1, where we excavated a similar bell pit filled with aeolian sand and containing charcoal dated at $31,600^{+3,600}_{-2,500}$ yr BP (GrN-11298). Mining probably only took place when Upper Palaeolithic man came near Nazlet Khater, where he knew fresh chert to be available.

During the 1980 season a narrow (0.2–0.4 m) grave (1.6 m length and 0.6 m deep) was found on the summit of the boulder hill (Fig. 1). Within the grave was a corpse, lying at full length on its back, with the arms stretched along the body. The covering consisted of several boulders, some more than 0.4 m in diameter. The interstices were filled with loose aeolian sand. A tool was laid on the bottom of the grave, at the right of and next to the

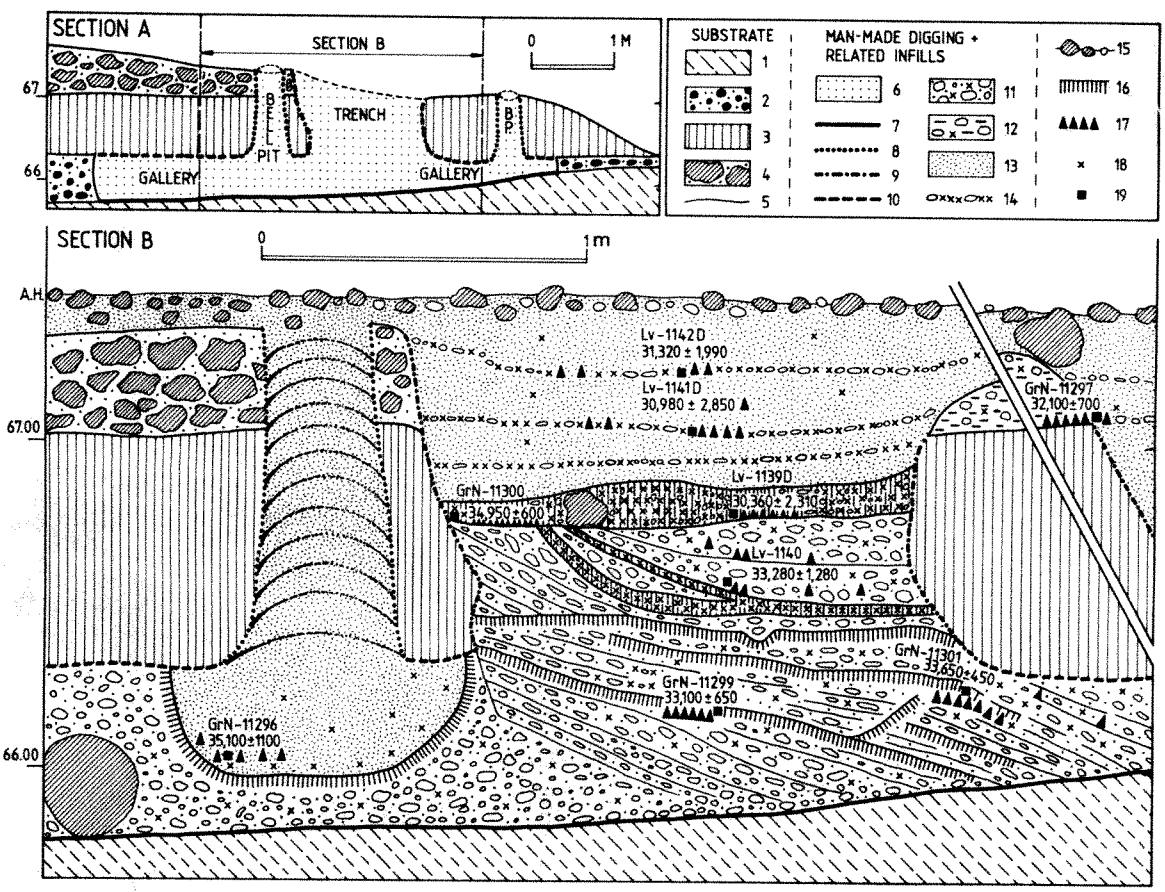

Fig. 2 General (A) and composed (B) section of the site Nazlet Khater 4. 1, Greenish silts and fine sands; 2, Nile gravels; 3, brown silts; 4, wadi deposits; 5, lithological contacts; 6, extent of the exploitation; 7, base of the mining activities; 8, walls of the bell pit; 9, walls of the trench; 10, gallery roof; 11, man-made gravel infills; 12, surface dumps; 13, aeolian sands; 14, derived gravels and artefacts; 15, desert pavement; 16, calcrete; 17, charcoal; 18, Upper Palaeolithic artefacts; 19, ^{14}C-dates in yr BP.

cranium. It is a bifacially shaped axe with concave sides and a convex cutting edge (Fig. 3*c*).

From the state of synostosis of most epiphises and other age indicators, the nearly complete skeletons seems to belong to a sub-adult individual, probably a male, with an estimated height of 1.65 m according to the formulae of Olivier *et al.*[4]. Cranial morphology is certainly that of anatomically modern man. We estimate the cranial capacity to be at least 1,400 cm^3. The facial skeleton displays two 'African' characters: fossa praenasalis and strong alveolar prognatism.

The best-preserved bone is the extremely robust mandible (Fig. 4). Its chin is fully developed. Ramus height (Martin 70)[5] is 72 mm and ramus breadth (Martin 71) is 51 mm. This breadth is very large and is matched only by that of the Mauer mandible. The rameal index is 70.83. According to its published photograph, the probably Aterian mandible of Dar-es-Soltan-2[6] (Morocco) must have a rameal index similar to that of the Nazlet Khater man.

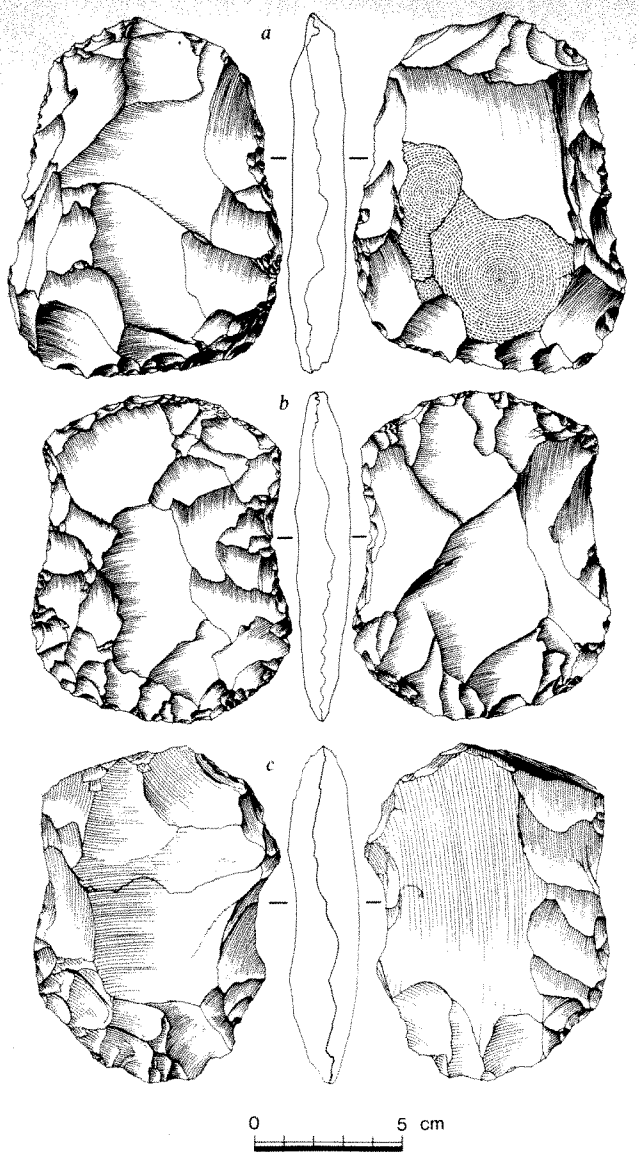

Fig. 3 Upper Palaeolithic axes. *a*, *b*, Axes of NK 4; *c*, burial gift from the grave on Boulder Hill.

The 1982 research shows that the early Upper Palaeolithic blade production on the site of Nazlet Khater 4 is related to chert mining. By about 33,000 yr ago, early Upper Palaeolithic man had acquired typical mining techniques. Indeed, even if the bell pits are only 1.5 m deep, this mining system is comparable with that in general use during the Neolithic[7]. These techniques were so complex that one has to accept that Upper Palaeolithic man chose the bell pit location on the basis of some geological insight.

Extraction pits of raw material to a depth of 0.35 m have been reported from the Nubian Middle Palaeolithic site of Arkin 5[8]. In other parts of the world chert mining was mainly restricted to the Holocene less than 10,000 yr ago. Only ochre extraction[9] took place before that.

Direct dating of the Nazlet Khater man is not possible as no collagen has been preserved in the skeleton bones. However, several arguments indicate that mining site and grave belong to the same prehistoric technocomplex, which is unique for the Nile Valley, and which was dated at 33,000 yr ago.

Indeed, the bifacial axe found near the cranium of the skeleton in the grave is of the same type as those of the mining site. Such axes are not known to occur in the later Palaeolithic of Egypt and predynastic axes are of a different type. Moreover, we have found no traces of predynastic occupation during our intensive regional survey.

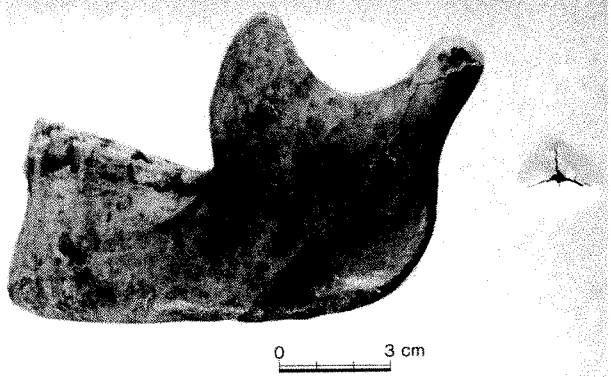

Fig. 4 Mandible (*norma lateralis*) of the Nazlet Khater man.

The boulder hill grave shows no evidence of the burial practices of the later Palaeolithic and predynastic periods, where the interred body is always in a contracted position.

The only prehistoric trenches filled up with aeolian sand are the grave, the mining site and the dated bell pit on the Nazlet Khater 1 site which suggests that a similar date for the aeolian sand in the grave is likely. A final argument for a very old age is the archaic features of the skeleton itself.

All these arguments strongly suggest that the Nazlet Khater man is around 30,000 yr old. In that case the man of Nazlet Khater is the oldest modern man in Africa north of the Equator.

We thank the Egyptian Antiquities Organisation, the Belgian Nationaal Fonds voor Wetenschappelijk Onderzoek, the Onderzoeksfonds van de Katholieke Universiteit Leuven, the Comité voor Belgische Opgravingen in Egypte, Dr H. De Meulenaere, Mr E. Gilot, Dr G. S. D. King, Mrs Hilde Marichal, Dr W. G. Mook and Dr H. Poppe for assistance.

The chorus-line hypothesis of manoeuvre coordination in avian flocks

Wayne K. Potts*

Department of Biology and Ecology Center, Utah State University, Logan, Utah 84322, USA

Thousands of birds flying together at high speeds are able to execute abrupt manoeuvres with such precise coordination that some investigators have postulated that 'thought transference'[1] or electromagnetic communication[2] must be taking place. Recently, Davis proposed that coordination is achieved by a 'threshold' number of birds executing 'preliminary movements' which signal to the flock that a turn is imminent[3]. Here I show by analysis of film of dunlin (*Calidris alpina*) flocks that a single bird may initiate a manoeuvre which spreads through the flock in a wave. The propagation of this 'manoeuvre wave' begins relatively slowly but reaches mean speeds three times higher than would be possible if birds were simply reacting to their immediate neighbours. These propagation speeds appear to be achieved in much the same way as they are in a human chorus line: individuals observe the approaching manoeuvre wave and time their own execution to coincide with its arrival.

* Present address: Department of Zoology, NJ-15 University of Washington, Seattle, Washington 98195, USA.

The 'chorus-line' hypothesis suggests that manoeuvres are initiated by any bird executing a manoeuvre towards the flock and that subsequent coordination is achieved through visual communication. This leads to the prediction that execution of the manoeuvre by neighbours of the initiator will be delayed by at least their own reaction time but, further away, response times should fall as birds are able to estimate the arrival of the approaching manoeuvre wave. Films taken of human chorus lines indicate that rehearsed manoeuvres, initiated without warning, propagate from person to person approximately twice as fast (107.7 ± 6.8 ms, $n = 3$) as the 194-ms human visual reaction time[4].

Coordinated manoeuvres (defined as those in which interbird response times were faster than laboratory measured reaction times) were investigated by field observations and analyses of 2,000 ft of slow-motion (50 frames s^{-1}) 16-mm film taken of dunlin flocks at Puget Sound, Washington. Manoeuvres were either natural or were induced artificially by shooting an arrow near an airborne flock. Twenty-two coordinated and four non-coordinated manoeuvres, chosen for clarity of detail, were analysed frame-by-frame. Startle reaction times to a light flash were measured in the laboratory using previously reported methodology[5].

In films where initiators and all neighbours were discernible, coordinated manoeuvres were initiated by one or a few individuals (one initiator, $n = 9$; two, $n = 3$; three, $n = 2$; >three, $n = 0$). Birds were considered initiators when they began the manoeuvre before the rest of the flock. In all cases coordinated manoeuvres were initiated by birds banking towards the flock ($n = 22$). When flock members turned away from the flock, the flock either did not follow ($n = 16$), or did so at speeds too low to qualify as a coordinated manoeuvre (84.8 ± 15.5 ms, $n = 4$). Manoeuvres always propagated through the flock in a wave radiating from the initiation site. These waves were observed to travel along every major axis (including back to front), indicating that manoeuvres may be initiated from any region of the flock. They had a mean propagation time from neighbour to neighbour of 14.6 ± 6.7 ms ($n = 9$), considerably lower than the laboratory measured startle reaction time of 38.3 ± 3.1 ms ($n = 110$). Therefore, manoeuvres propagate through flocks in waves travelling at speeds nearly three times faster than possible if flock members are following the actions of adjacent neighbours. However, the first neighbours to respond to the initiator required 67 ± 24 ms ($n = 14$). This mean propagation time from initiator to neighbours was significantly slower than both the mean manoeuvre propagation time (14.6 ms, $P < 0.0001$), and the mean species reaction time (38.3 ms, $P < 0.0001$; Wilcoxon rank sum test).

These results show that manoeuvres initially propagate more slowly than the birds' reaction time and then accelerate to high propagation speeds, as predicted by the chorus line hypothesis. Alternative hypotheses make no explicit predictions about the form of propagation, but imply that manoeuvres can occur in unison. No unison manoeuvres were seen. No preliminary movements which might signal that a turn is imminent[3] were seen, although such movements should be visible on film if they are to be visible to what is often thousands of tightly packed[6] flock members.

Flock members always appear to follow the lead of initiators banking towards the flock. This 'dictatorial' rule by initiators presumably prevents indecision and allows flocks to respond rapidly during attacks by birds of prey, which are a major source of mortality for flocking shorebirds[7]. Birds of prey usually direct their attack toward individuals isolated from the main flock[7,8], and this may well have exerted selection pressure for the evolution of coordinated manoeuvres.

Auditory receptive fields in primate superior colliculus shift with changes in eye position

Martha F. Jay & David L. Sparks

Department of Physiology and Biophysics, and the Neurosciences Program, University of Alabama in Birmingham, University Station, Birmingham, Alabama 35294, USA

The process by which sensory signals are transformed into commands for the control of movement is poorly understood. A potential site for such a transformation is the superior colliculus (SC), which receives auditory, visual and somatosensory inputs[1–3] and contains neurones that discharge before saccadic eye movements[4–6]. Along the primary sensory pathways, signals coding the spatial location of auditory, visual and somatosensory targets are based on distinctly different coordinate systems, and it is not known whether each type of sensory input uses a separate motor pathway or if they are converted into a common coordinate system in order to share a single pre-motor circuit. Sensory neurones in the SC have spatially restricted receptive fields (RFs) and are organized into maps across the collicular surface[7–9]. Acute experiments have shown a rough correspondence between the spatial positions of RFs of neurones encountered along a single dorsal–ventral penetration of the colliculus, regardless of the modality of the effective stimulus[10–14], suggesting that auditory, visual and somatosensory maps might be in register. However, in these conditions the head-centred auditory system and the retinotopic visual system are aligned because the eyes are in the primary orbital position[15]. Moreover, other data have suggested[16–18] that the primate SC is organized in motor, not sensory, coordinates, although in the cat, eye position was found to have no effect on auditory receptive fields[19]. We therefore sought here to determine what happens to the registration of the auditory and visual maps in the alert, behaving animal. Monkeys, with heads fixed, were trained to make delayed saccadic eye movements to auditory or visual targets from one of three initial fixation points while the activity of single neurones was recorded extracellularly. We found that the auditory receptive fields shifted with changes in eye position, allowing the auditory and visual maps to remain in register.

We trained two monkeys (*Macaca mulatta*) to look to either visual or auditory targets in a completely darkened room. The major objective of the experiment was to plot the RFs of sound-sensitive cells in the SC of alert monkeys while varying the direction of visual fixation. We considered that if the RFs of these auditory neurones were organized in head-centred coordinates, this manipulation would have no effect, whereas if the auditory neurones use oculomotor coordinates, the direction and distance of the sound source from the eyes, not the absolute position of the target in space, would be the crucial factor. Accordingly, the magnitude of the neural responses would depend on both the position of the speaker relative to the head and the position of the eyes in the orbit.

Another objective was to determine whether auditory and visual pathways share a common motor circuit. The activity of some collicular neurones is tightly coupled to saccade onset and is thought to participate in the initiation of spontaneous and

visually-triggered saccades[4–6]. If the neurones that burst before visually-guided saccades also burst before saccades to auditory targets, this would suggest that auditory and visual signals have been converted into the same coordinates by the time they reach the level of the SC.

The monkeys were placed, with their heads fixed, in the centre of a semicircular track[20]. Under computer control, a speaker moved along the track and the hoop rotated so that the target could be placed anywhere on an imaginary sphere surrounding the animal. A light-emitting diode in the centre of the speaker was used to compare auditory and visual responses. Three fixation lights were placed 24° apart along the horizontal meridian.

The auditory stimulus was a broad-band noise burst (20–20 kHz; 90 dB sound pressure level; re: 0.0002 dyn cm^{-2}). The visual stimulus, a green light-emitting diode, subtended a visual angle of 12 arc min. Eye position was monitored using the scleral search coil technique[21]; tungsten microelectrodes were used for extracellular unit recordings.

A delayed saccade task was used to separate temporally sensory and motor activity. At the beginning of each trial, one of the three fixation lights was randomly activated. After a variable time, an auditory or visual target was presented. To receive a liquid reward, the monkey had to maintain fixation of the initial light until it was extinguished and then look to the peripheral target.

For every sound-sensitive cell encountered, the position of the eyes in the orbit had a distinct effect on the neural response to an auditory stimulus. Figure 1*a* illustrates data recorded from a single cell. For these trials, the speaker was located 20° to the right and 6° above the primary eye position. When the gaze was directed towards the left fixation target, the auditory stimulus evoked a vigorous neural discharge with latencies ranging over 40–60 ms. When the monkey was viewing the centre or right fixation lights, identical noise bursts presented in the same spatial location resulted in neural responses that were either markedly attenuated or completely absent.

Figure 1*b* summarizes the data obtained from this cell by plotting the average number of spikes in response to the noise burst against the horizontal position of the speaker (top). The RF of the neurones shifted with the position of the eyes in the orbit. The peripheral boundary of these RFs could not be determined because of the experimental constraint of keeping the targets within the oculomotor range. These data are replotted using the motor error reference system below. The abscissa represents horizontal motor error, or the horizontal component of the eye movements required to look to the auditory targets from the three fixation points. In this case, the data obtained while the monkey viewed the three fixation lights are closely aligned. Thus, the magnitude of the discharge of this neurone was not determined solely by the position of the auditory stimulus in space, but depended jointly on the position of the eyes in the orbit and the target position. Individual cells in the sample varied with respect to the relative strength of the head-centred and motor error signals they carried, but all auditory units analysed ($n = 116$) displayed a shift in RF location with changes in eye position.

Like many visually responsive cells in the intermediate layers of the SC[16], these auditory neurones could not be classified as strictly sensory or motor cells but seemed to exhibit qualities of both systems. Their responses appeared to be sensory in that the discharge was time-locked to the onset of the stimulus. The average latency was ~50 ms for auditory targets and 70 ms for visual ones. Many of the auditory cells could be activated by either auditory or visual stimuli. For these bimodal cells, the vigour of the neural response depended on target modality even though identical motor responses might occur. Some cells discharged more vigorously to auditory stimuli, others to a visual target. In an attempt to dissociate the sensory and motor components of the response, we plotted the auditory fields while the monkey performed a probe task—one that required continuous fixation of the initial light without making a saccade towards the auditory or visual probe stimulus. Most cells rapidly habituated when a motor response was not required. For the remaining cells, the RFs obtained using probe trials were very similar to those generated with the delayed saccade paradigm even though no eye movement occurred. Yet this sound-induced activity cannot be termed 'sensory' because the response depended on the trajectory of the eye movement required to look to the auditory target.

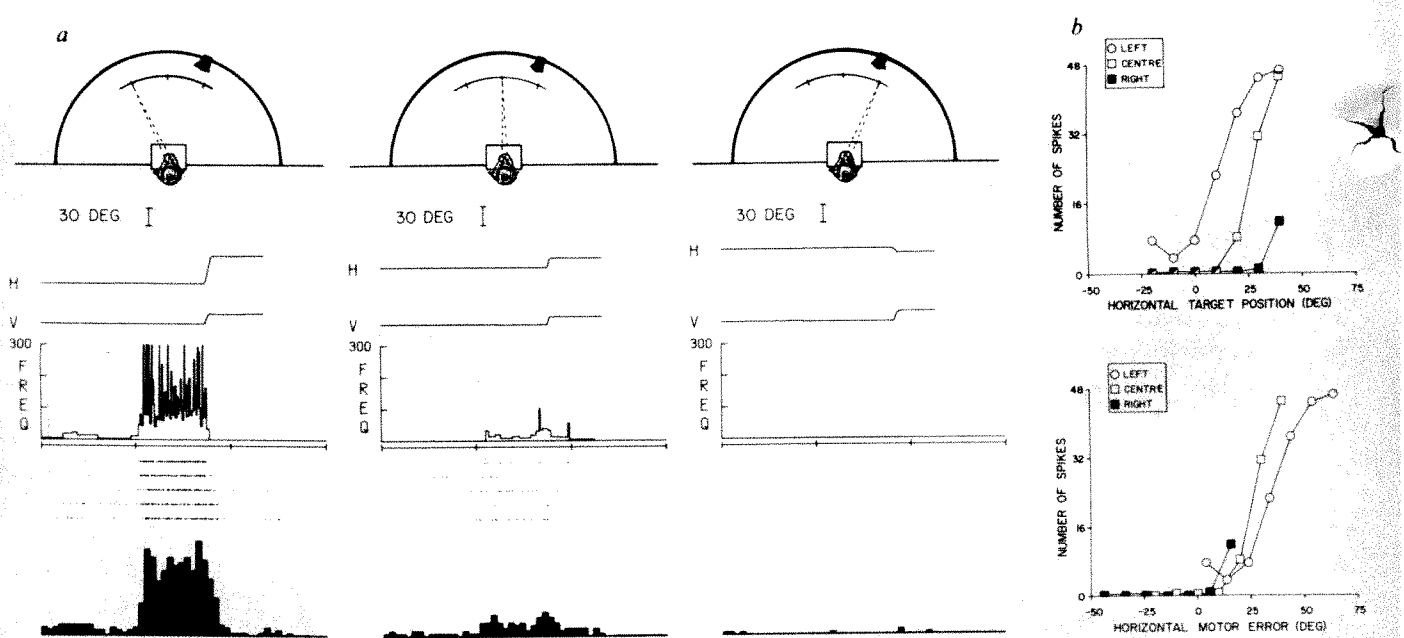

Fig. 1 The effects of eye position on the response of a single SC cell to an auditory stimulus. *a*, The speaker was placed 20° right, 6° up from centre while the fixation position was varied between 24° left (left), centre (centre) and 24° right (right). Time base was 3 s and the target was presented at 1 s. Horizontal (up–right) and vertical eye position traces are shown in the top row. Representations of instantaneous firing rate for single trials are in the second row, followed by rasters showing the unit activity for five trials. The bottom row is a cumulative histogram for these trials. *b*, A summary plot of the auditory RFs for this one cell as a function of horizontal target position (top) showing a shift in the position of the RFs as eye position was varied. The data are replotted below in motor error coordinates—the difference between current eye position and the saccade target. The fields are better aligned in the motor error reference system than in the one based on the position of the target relative to the head.

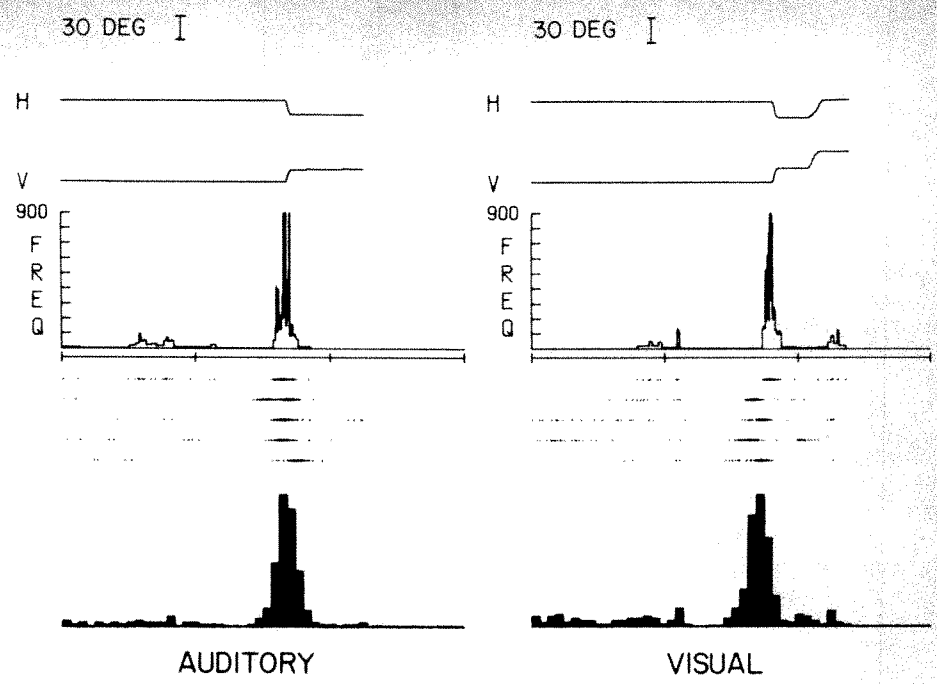

Fig. 2 The convergence of auditory and visual pathways onto a common motor circuit. A single SR burst cell activated before both auditory (left) and visual (right) saccades to a target located 16° left, 10° up. No burst occurred for either modality when a saccade to this same target was initiated from the left fixation point.

As recent work in the cat SC has shown that the position of the pinnae has a significant effect on the spatial properties of auditory cells[22–24], we sought to evaluate the possible contribution of pinna movements in the primate. The RFs were compared in the same cell when the animal was free to move its ears and when the pinnae were mechanically restrained. The field plots were similar in both conditions, indicating that the small pinna movements made by primates are not responsible for the eye position effect observed in this study.

SC neurones that burst before visually initiated saccades were also found to burst before saccades to auditory targets. The activity of a typical saccade-related (SR) burst neurone is illustrated in Fig. 2. With gaze directed at the centre fixation SR burst cells tested in this manner. Thus, at the level of the SC, auditory and visual signals share a common motor circuit.

Our findings suggest that an internal representation of eye position, either efference copy or proprioception, has been subtracted from the head-centred spatial code of auditory targets found elsewhere in the auditory system. As a result, some auditory cells code for the vector of a potential eye movement rather than just the position of a sound source relative to the head. The fact that the auditory cell population we observed displayed a range in the relative potency of motor error and head-centred signals suggests that this transformation may occur in the primate SC. This translation allows the auditory and visual maps in the intermediate and deep layers of the primate SC to share a reference system (motor error) and to converge onto a common motor pathway for the generation of saccadic eye movements.

We acknowledge programming assistance from Kathy Pearson, technical help from Ken Hamrick and Robert Deich, and timely insights provided by Dr Lawrence Mays. This work was supported by grants EY01189 and EY03039. Preliminary results have been reported elsewhere[25].

Association with persistent neuroleptic-induced dyskinesia of regional changes in brain GABA synthesis

Lars-M. Gunne, Jan-Erik Häggström & Birgitta Sjöquist

Psychiatric Research Centre, Ulleråker Hospital, S-750 17 Uppsala, Sweden

The movement disorder tardive dyskinesia is a serious side effect of the long-term treatment of schizophrenia with neuroleptic drugs. Similar symptoms to those of tardive dyskinesia have been observed in *Cebus apella* monkeys following long-term treatment with neuroleptic drugs[1,2], and these monkeys may therefore be a useful animal model of tardive dyskinesia. Motor defects have persisted in these dyskinetic monkeys for periods of 1–6 yr after the cessation of neuroleptic treatment. We report here that in three regions of the brains of dyskinetic monkeys (substantia nigra, medial globus pallidus and subthalamic nucleus) glutamate decarboxylase activities and γ-aminobutyric acid (GABA) levels are reduced relative to control monkeys that had been treated with neuroleptics but which showed none of the symptoms of tardive dyskinesia. These results suggest that alterations in the GABA neurone system are involved in neuroleptic drug-induced tardive dyskinesia.

Nineteen *C. apella* monkeys (10 male, 9 female) weighing 1.6–4.2 kg (mean 2.9 kg) were used in the present experiments. Twelve monkeys received chronic neuroleptic treatment: haloperidol (nine animals) or fluphenazine (three) for 3–6 yr, while seven were untreated controls. Intramuscular (i.m.) injections of haloperidol decanoate (1–10 mg per kg) or fluphenazine decanoate (4–10 mg per kg) were given at 3-week intervals. After varying treatment periods, six of these monkeys (three injected with haloperidol, three with fluphenazine) developed persistent choreic dyskinetic movements in the trunk, neck and extremities (one monkey also had oral dyskinesia). The frequency of dyskinetic movements and symptom intensity were rated during 2-min sessions[3]. When these measurements were made at 1 and 60 days after the final neuroleptic injection, only slight changes in intensity of dyskinetic symptoms were evident.

Throughout the present study three groups of animals were compared: untreated controls ($n = 7$), neuroleptic-treated controls ($n = 6$) and dyskinetic animals ($n = 6$). Before the neuroleptic-treated animals were killed the regular depot drug was substituted by a single i.m. injection of non-depot haloperidol or fluphenazine (0.05 mg per kg). Two months after the final injection, the animals were killed under brief methohexital anaesthesia. Within 10–12 min of killing the brains were removed and stored at −80 °C. Microdisks (1.075 mm^3) were later punched from successive coronal sections prepared from the frozen brains. Glutamic acid decarboxylase (GAD) activity was measured as $^{14}CO_2$ formation from [1-^{14}C]glutamic acid during 30 min in the presence of pyridoxal-5-phosphate[4]. GABA, homovanillic acid (HVA) and dihydroxyphenylacetic acid (DOPAC) were assayed by gas chromatography–mass spectrometry in the selected ion-monitoring mode using deuterium-labelled internal standards[5,6]. In most animals only the left half of the brain was analysed, but in six (two untreated controls, one neuroleptic-treated control and three dyskinetic monkeys) both sides were compared (one of the dyskinetic monkeys had one-sided symptoms).

Mean levels of transmitter markers at each brain site were compared between the three groups of monkeys using independent Student's *t*-tests. In addition, all values obtained for a certain brain nucleus were combined and means for each nucleus were compared using *t*-tests between the three groups. In one case (see Fig. 1) sign-tests and χ^2-tests were used.

The neuroleptic-treated monkeys which did not develop dyskinesia (neuroleptic-treated controls) did not differ significantly from untreated controls in any brain region with regard to GAD activity and levels of GABA, HVA or DOPAC, whereas the dyskinetic animals showed a characteristic pattern of regional changes. Table 1 shows regional GAD activity and GABA levels for untreated controls and per cent changes within both neuroleptic-treated groups. The dyskinetic monkeys showed a reduced GAD activity in the substantia nigra, nucleus subthalamicus and medial globus pallidus and GABA was low in the substantia nigra and n. subthalamicus. In all other brain areas group differences for GAD and GABA were insignificant. In Fig. 1 the mean nigral GAD activity for each individual monkey has been plotted against the number of animals. The dyskinetic group differed from the controls (χ^2 tests, $P < 0.001$), verifying that the number of animals was sufficiently large to allow generalized conclusions regarding relations between state (dyskinetic versus non-dyskinetic) and biochemical changes.

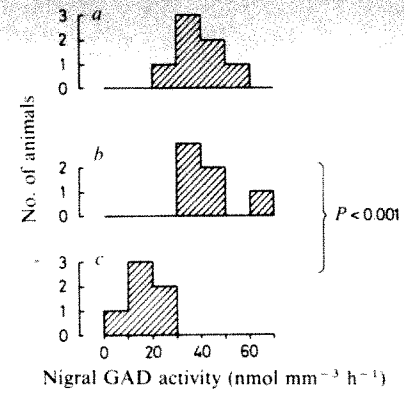

Fig. 1 Distribution of individual (mean) GAD activity levels in substantia nigra in three groups of monkeys: *a*, untreated controls; *b*, neuroleptic-treated controls; and *c*, dyskinetic animals.

GAD activity in substantia nigra was generally equally high on both sides; a conspicuous exception was found in one animal with unilateral dyskinesia in the left hand and arm. In this animal there was a depression of GAD activity only in the opposite (right) nigral area (15.3 nmol mm^{-3} h^{-1}), whereas the ipsilateral nigra had a mean value in the normal range (41.0 nmol mm^{-3} h^{-1}).

The HVA levels were significantly reduced in the caudate nucleus and substantia nigra of dyskinetic animals (Fig. 2). In

Values plotted are means ± s.d. Significance levels: * $P < 0.05$, † $P < 0.01$.

the caudate there was also a reduction of DOPAC. In all striatal areas studied (20 in the caudate, 16 in putamen) the mean levels of transmitters in dyskinetic animals were lower than in neuroleptic-treated controls. The greatest depression was found in corpus nuclei caudati and in some nigral areas (unfortunately the technique did not allow us to differentiate between nigra reticulata and compacta).

When striatal dopamine transmission is blocked by neuroleptic drugs this, by trans-synaptic mechanisms, elicits a series of changes in activity elsewhere in the brain[7]. The turnover of GABA in the substantia nigra is lowered[8], which in turn has effects on nigral efferents under tonic inhibitory control from the striatonigral GABA neurone system[9–12]. In the present experiments we noted a lowered GAD activity and/or reduced GABA levels in three brain areas: the substantia nigra, globus pallidus medialis and the subthalamic nucleus. These signs of a reduced GABA function in three brain nuclei were evident only in dyskinetic animals and are probably due to longstanding local depression of GABA neurone activity. Thus, even if all monkeys display local GABA depression during neuroleptic drug administration, only the dyskinetic animals fail to recover their GABA function after withdrawal of the drug.

Further evidence of a connection between dysfunction of nigral GABA and movement disorders is provided by the observation that intra-nigral injection of GABA antagonists precipitates oral dyskinesia in rats[13]. In this context it is noteworthy that low nigral and striatal levels of GABA and GAD have been reported in patients dying of Huntington's chorea, another chronic dyskinetic condition[14,15]. Low nigral GAD activities have also been reported in subjects suffering from Parkinson's disease—again this is secondary to the impaired striatal dopamine transmission, since L-dopa seemed to retain nigral GAD activity at normal levels[16]. Analogously, intrastriatal injection of dopamine has been reported to increase glucose utilization in those areas (substantia nigra, globus pallidus medialis and subthalamic nucleus) where we noticed a reduction of GAD activity in our dyskinetic monkeys[17]. A reduction of nigral GAD activity has also been found in rats made dyskinetic by chronic haloperidol administration[4]. GAD is known to be preferentially located in GABA neurone terminals[18]. Whether the low GAD activity in the three brain areas reported here is due to a reduced tissue density of GABA terminals (that is, caused by neuronal cell degeneration) or a reversible functional depression, must await histological evidence.

The reduced nigral and striatal dopamine metabolism in dyskinetic monkeys would seem incompatible with a dysfunctioning striatonigral GABA system if this is regarded as a link in a negative feedback control of nigrostriatal dopamine nerves. If this feedback loop hypothesis[19–23] were correct, an impairment of its GABAergic link would be expected to increase rather than reduce the turnover rate of dopamine. However, this hypothesis has been disputed and the possibility of a positive feedback has occasionally been proposed[24]. The finding that GABA agonists injected into the substantia nigra reticulata induce contraversive turning and an increased turnover of dopamine in the striatum[12,25–28] supports the notion that dopamine neurones are subjected to positive feedback.

Supersensitivity in striatal dopamine receptors has been suggested as the main cause of tardive dyskinesia[29,30]. However, when rats are given neuroleptic drugs they develop such supersensitivity to dopamine agonists even after a single injection[31]. Further, this phenomenon is not irreversible and thus poorly if at all related to dyskinetic movements continuing for months after neuroleptic drug withdrawal. The present paper instead seems to link persistent dyskinesia with a weakness in the GABAergic neurone system induced by trans-synaptic mechanisms in neurones remote from the striatal dopamine receptor.

This study was supported by Swedish MRC grant 4546 and by the Knut & Alice Wallenbergs' Foundation.

Chronic neuroleptic treatment enhances neurotensin receptor binding in human and rat substantia nigra

George R. Uhl*† & Michael J. Kuhar*

Antischizophrenic neuroleptic drugs interact with brain dopamine systems in producing both therapeutic and unwanted side effects[1]. Short-term administration of neuroleptics may produce a parkinsonian, hypokinetic syndrome mimicking symptoms of dopamine depletion, and presumably caused by dopamine receptor blockade[2]. Paradoxically, some 20% of patients treated chronically with these agents develop tardive dyskinesia. The adventitious movements typical of this condition mimic symptoms of dopamine excess despite continuing receptor blockade[3–5]. Dopamine receptor supersensitivity does develop in such conditions, but its extent does not correlate well with the presence or absence of tardive dyskinesia[6]. Exploration of neuroleptic-induced alterations in other dopamine-associated systems may thus provide insight into these processes. Dopamine-containing cells of the substantia nigra, prominently implicated in the motor side effects of neuroleptics, possess dense concentrations of receptors for the putative peptide neurotransmitter, neurotensin[7–9]. Here we report that these receptors are substantially increased in both rats and humans after chronic treatment with neuroleptic drugs, and discuss possible implications of this finding for our understanding of neuroleptic actions.

Neurotensin is a central nervous system neurotransmitter candidate anatomically disposed to interact with dopaminergic neurones[10–13]. In particular, several lines of evidence indicate that there are dense localizations of neurotensin receptors on neurones in the substantia nigra from rats and human tissue. Autoradiographic studies demonstrate dense concentrations of neurotensin-binding sites in the substantia nigra that are depleted by rat and human lesions destroying dopamine-containing cells[7–9,14]. The neurotensin receptors appear to be physiologically active. Intracisternal neurotensin administration depletes striatal dopamine levels[15], while microiontophoretic application of the peptide selectively excites nigral compacta neurones[16]. Neurotensin potently enhances dopamine release from striatal slices[17]. We have examined these nigral neurotensin receptors in rats and humans with and without chronic neuroleptic (haloperidol) treatment.

Sprague–Dawley rats (200 g) were injected subcutaneously (s.c.) daily for 4 weeks with 0.5 mg per kg of either haloperidol or vehicle alone, according to the regimen of Burt *et al.*[18]. Frozen midbrain slabs taken from brains of drug-treated patients with schizophrenia and from neurologically normal controls (given by Drs Wallace Tourtellotte and Peter Whitehouse) were maintained at −70 °C until sectioning (see Fig. 3 legend for details). Neurotensin receptor autoradiography was performed as described elsewhere[7]. Briefly, a 60-min incubation with 4 nM ^{3}H-neurotensin (86 Ci mmol^{-1}; NEN) was followed by two 5-min washes, then rapid drying of the tissue. Serial sections incubated in medium containing 5×10^{-6} M unlabelled neurotensin (Peninsula) and ^{3}H-neurotensin served as 'blank' controls. Autoradiography was performed using the emulsion-coated coverslip technique (Kodak NTB 3). After 6 weeks of exposure, the emulsion was developed and the tissue stained with toluidine blue. For 'saturation' analysis, sections from two haloperidol-treated rats, two control rats, two neuroleptic-treated schizophrenics, and two neurologically normal control patients were incubated in 10^{-7} M labelled neurotensin, as

SNR, substantia nigra pars reticulata; SNC, substantia nigra pars compacta; IPN, interpeduncular nucleus; RN, red nucleus; PAG, periaqueductal grey; PN, nucleus paranigralis; S. COLL, superior colliculus. *b*, Darkfield photomicrograph of ^{3}H-neurotensin autoradiogram of the basal midbrain from a control saline-injected rat. *c*, Same as *b* for haloperidol-injected rat. *d*, 'Blank' section adjacent to *a*, incubated with 5×10^{-6} M unlabelled neurotensin and 4 nM ^{3}H-neurotensin to establish a control. ×32.

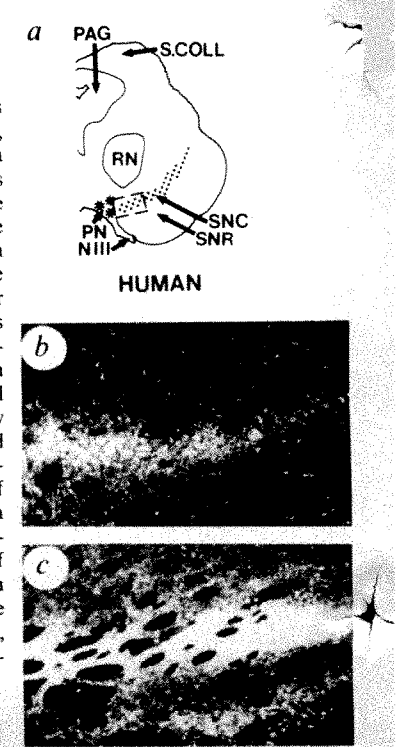

Fig. 2 Neurotensin receptors in human basal midbrain. *a*, Diagram of the midbrain area shown in *b*, *c*. (Box represents the approximate location of the photographs; it is smaller here than in Fig. 1 as the human nigra is ~5 times larger than the rat nigra.) NIII, oculomotor nerve. Other abbreviations as for Fig. 1. *b*, Darkfield photomicrograph of ^{3}H-neurotensin autoradiogram of the basal midbrain from a neurologically normal human. *c*, Darkfield photomicrograph of ^{3}H-neurotensin autoradiogram of the basal midbrain from a schizophrenic, neuroleptic-treated human. Broadening of the zone of dense neurotensin receptor grains is evident in the human nigra, as in the rat nigra, following neuroleptic treatment. ×36.

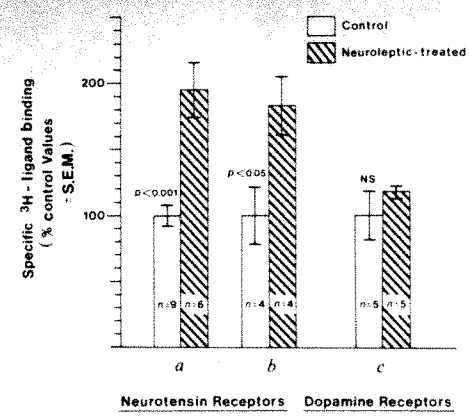

Fig. 3 Histogram of neurotensin (*a* and *b*) and dopamine (*c*) receptor densities in substantia nigra of normal and neuroleptic-treated humans (*a*) and rats (*b* and *c*). *a*, Specific ^{3}H-neurotensin receptor binding levels in substantia nigra specimens from neuroleptic-treated schizophrenic patients and neurologically normal humans without known neuroleptic treatment. Mean age of the control patients was 51; that of the schizophrenics 50. Mean postmortem interval for control brains, 22 h; for schizophrenics, 29 h. The age, postmortem interval, disease duration, cause of death and medication regimen of the six drug-treated human schizophrenic patients were as follows: S1: 36 yr, 27 h; >15 yr, ? overdose, fluphenazine/thioridazine/doxepin/molindon. S2: 36 yr, 41 h, ? 15 yr, gunshot wound, chlorpromazine/thiothixene/fluphenazine/trifluoperazine. S3: 46 yr, 24 h, 20 yr, myocardial infarction, fluphenazine. S4: 51 yr, 29 h, "years", aspiration, loxapine. S5: 64 yr, 39 h, 12 yr, bowel perforation, chlorpromazine/trifluoperazine. S6: 67 yr, ~12 h, "years" ?overdose, ?haloperidol. The age, postmortem interval and cause of death for nine neurologically normal control patients without histories of neuroleptic use were as follows. N1: 30 yr, 33 h, multiple trauma. N2: 36 yr, 19.5 h, myocardial infarction. N3: 40 yr, 42 h, myocardial infarction. N4: 40 yr, 19 h, sudden death. N5: 42 yr, ~18 h, myocardial infarction. N6: 61 yr, 23 h, myocardial infarction. N7: 65 yr, ~12 h, myocardial infarction. N8: 66 yr, 16 h, gunshot wound. N9: 77 yr, ~12 h, ruptured aorta. *b*, Specific ^{3}H-neurotensin receptor binding levels in substantia nigra specimens from rats treated for 1 month with 0.5 mg per kg per day of either haloperidol s.c. or vehicle alone. *c*, Dopamine receptor binding (ADTN (2-amino-6,7-dihydroxy-1,2,3,4-tetrahydronapthalene)–displaceable ^{3}H-spiroperidol binding) to rat substantia nigra sections adjacent to those assayed for ^{3}H-neurotensin binding in *b*. (Data from G.R.U., P. Whitehouse, D. Price and M.J.K., in preparation.)

described above, and exposed to coverslips for 3 weeks. Dopamine receptors were labelled as described elsewhere[19]. We counted grains overlying the substantia nigra zona compacta, ~400 μm from its medial border. Three 1,000-μm^2 regions of each substantia nigra were counted manually in each case. The data presented here derive from the substantia nigras of nine normal humans, six drug-treated schizophrenic patients, five saline-injected rats and five haloperidol-injected rats. Values for adjacent 'blank' sections from these same regions were subtracted from the values obtained to yield 'specific' grain counts. Statistical calculations (Student's *t*-test, Pearson correlation coefficient) were performed using a Hewlett–Packard programmable calculator.

In the control human brains, and in rat brains, receptor distributions in the basal midbrain were similar to those reported previously[7–9]. High densities of receptor grains overlying the substantia nigra and ventral tegmental area contrasted with much lower levels over the cerebral peduncles and red nucleus (Figs 1*b*, 2*b*). These high grain densities were 6–10 times the levels noted in adjacent 'blank' sections incubated in the presence of unlabelled neurotensin (Fig. 1*d*). Values obtained for human blank samples were also less than one-sixth of total nigral binding. Densities of receptors in human control cases did not correlate significantly with either patient age or postmortem interval ($P > 0.1$ in each case).

Binding of labelled neurotensin in the substantia nigra was substantially increased in both rats and humans treated with neuroleptics (Figs 1*c*, 2*b*). There was almost a doubling of receptor densities in both species, with only slight overlap between normal and drug-treated values ($P < 0.05$ for rats; $P < 0.01$ for humans) (Fig. 3*a*, *b*).

Saturation analysis suggested that this alteration in receptor binding was principally due to alterations in receptor number, as we found the same relationship between treated and untreated individuals. Human schizophrenic tissue showed 1.8 times the binding in normal control tissue, while drug-treated rats revealed 1.9 times, however, control binding. Our ability to detect subtle changes in the affinity constant, K_D, using this paradigm is, however, limited.

Could these results be due to direct neuroleptic influences on peptide binding? In *in vitro* binding assays performed using homogenates or tissue sections, concentrations of haloperidol up to 10^{-5} M were ineffective in displacing or augmenting neurotensin binding, making this an unlikely possibility (G.R.U., unpublished data)[10].

Recently, Mazella *et al.* described[20] high- ($K_D = 0.1$ nM) and low- ($K_D \sim 4$ nM) affinity binding sites for ^{125}I-neurotensin; we might expect ~50% occupancy of lower affinity and ~97% occupancy of higher affinity sites in our binding conditions. It is possible that we have labelled both of these sites in our studies[20].

These results may have implications for understanding receptor regulation, and might provide insight into neuroleptic drug effects. Chronic administration of neuroleptic, dopamine receptor-blocking drugs has been associated with several brain changes. Nigrostriatal receptors for dopamine, especially the D-2 subtype, and for cholecystokinin peptides are increased by ~20% by neuroleptics[6,18,21]. We have observed similar quantitative changes in autoradiographic dopamine receptor binding in our rat brains, although these alterations did not reach statistical significance with our small sample (G.R.U., P. Whitehouse and M.J.K., in preparation; Fig. 3*c*). In the present study, neuroleptic-induced neurotensin receptor changes were of substantially greater magnitude than alterations in the density of other receptors influenced by these drugs. Recent electron microscopic studies revealing increased numbers of terminals on nigral dendrites in neuroleptic-treated animals could provide a possible anatomical correlation with the present results[22]. Interestingly, the increased population of nerve endings possesses properties characteristic of (though not diagnostic of) peptide-containing terminals[23–26]. Conceivably, presynaptic as well as postsynaptic peptidergic mechanisms could be involved. Neurotensin levels are elevated in some brain areas in neuroleptic-treated rats and schizophrenics, though nigral peptide levels have not been examined[27,28].

These results seem to provide an example of 'autoregulatory' responses extending beyond changes in drug-blocked receptors to include other receptor types on the same cell. The increased density of neurotensin receptors could lead to increased excitability of dopamine cells, and partially supercede the effects of dopamine receptor blockade. Whether such an effect could occur at the level of the individual cell, or whether it requires polysynaptic feedback circuits such as those provided by striatonigral projections awaits further study.

The magnitude of the neuroleptic-induced neurotensin receptor change and its occurrence in both rat and human brains are consistent with a possible role for these peptide receptor alterations in the clinical expression of long-term neuroleptic effects such as tardive dyskinesia. Augmented neurotensin receptor densities on nigrostriatal neurones could possibly lead to increased dopamine release from these neurones, and hence to motor symptoms of dopamine excess. Conceivably, elucidation of neuroleptic-induced alterations in nigral neurotensin receptors could enhance our understanding of the motor side effects of frequently used neuroleptic drugs.

We acknowledge the support and helpful suggestions of Drs S. Snyder and D. Price; the invaluable assistance with specimen collection of Drs W. Tourtellotte, Peter Whitehouse, Charles White III and Juan Troncoso; technical assistance from Ms Naomi Taylor, Gail Hackney and Susan Goehring; and manuscript preparation by Ms Darlene Weimer and Mrs Mary Flutka. These experiments were supported by grants from the NIMH (MH25951 and a RCDA Type II award MH00053), the McKnight Foundation and the American Parkinson's Disease Association.

Cation selectivity of light-sensitive conductance in retinal rods

King-Wai Yau & Kei Nakatani

Department of Physiology and Biophysics, University of Texas Medical Branch, Galveston, Texas 77550, USA

Vertebrate photoreceptors respond to light by a membrane hyperpolarization which is thought to result from the decrease of a Na-selective conductance in the outer segment[1–6]. One hypothesis is that light increases intracellular free Ca which reversibly blocks the Na conductance[7,8]; at least part of this Ca is then extruded to the cell exterior by a Na–Ca exchanger at the plasma membrane[9–14]. We describe experiments here which show that the light-sensitive conductance in rods is also highly permeable to K. While external Na acts to keep the conductance open, external K tends to keep it closed, both actions probably involving the Na–Ca exchanger. The conductance is also permeable to the monovalent cations Li, Rb and Cs and the divalent cations Ca, Sr and Ba. The ability of both Na and K to go through the light-sensitive conductance explains the long-standing puzzle as to why the reversal potential for the light response is at 0 to +10 mV[15–17].

Under IR light a piece of retina from a dark-adapted toad (*Bufo marinus*) was finely chopped in Ringer's solution, yielding some isolated rods with intact outer and inner segments. The light-sensitive current from one of these rods was recorded by sucking its inner segment into a close-fitting glass pipette containing Ringer's solution while its outer segment was exposed to perfusing solution[13,14]. The solution exchange time as judged from junction currents[14] was about 200 ms, rapid enough to study the light-sensitive conductance before it collapsed upon removal of all external Na[14].

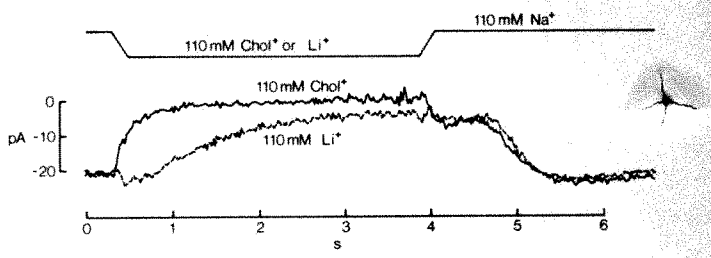

Fig. 1 Effects on the light-sensitive current in toad rod of complete replacement of Na in Ringer's by choline and Li. External Ca was maintained at 1 mM throughout. Recordings were made from the same rod with a current-to-voltage converter connected to the suction pipette. Time courses of solution changes, as indicated by junction currents, are shown above the traces.
Methods: The valve which controlled solution changes was operated pneumatically and with electronic timing so that the solution changes could be reproduced exactly many times. Traces were obtained from total recorded current (light-sensitive current plus junction current), measured in darkness, minus junction current, measured in a repeated run in bright light. Outward light-sensitive current across the outer segment is plotted upwards. In addition to 110 mM Na, choline or Li, the solutions also contained 2.5 mM K, 1.6 mM Mg, 1.0 mM Ca, 117.7 mM Cl, 5 mM tetramethylammonium (TMA)-HEPES, 5 mM dextrose and were buffered to *p*H 7.65. The choline trace is averaged from two dark minus two light trials; the Li trace is from the difference between single dark and light trials. All recordings were low-pass filtered at 100 Hz, 8-pole, and bright steady light for junction current measurements delivered 80–189 photons (500 nm) $\mu m^{-2} s^{-1}$, unpolarized.

The solid trace in Fig. 1 shows an experiment in which all Na in the perfusing Ringer's was briefly replaced by choline, a cation with little or no ability to go through the light-sensitive conductance[13,14,18]. The initial rapid reduction in current upon Na removal indicates removal of most or all of the Na current, while the small initial current jump upon restoring Na probably represents Na current going through a substantially lower light-sensitive conductance caused by the failure of choline to drive the Na–Ca exchanger and maintain open conductance. The delayed secondary increase in current probably reflects the gradual reopening of the conductance due to the reactivation of the Na–Ca exchanger by Na, which leads to lower internal Ca. The dashed trace in Fig. 1 was obtained from the same cell with Li replacing Na. There was no initial drop but rather a slight increase in current upon Li substitution, but thereafter the current did decline to a low level. Upon restoring Na there was no initial jump in current, but the secondary rise was identical to the choline case. These results suggest that Li goes through the light-sensitive conductance as well as or slightly better than Na but that it cannot run the Na–Ca exchanger. In the squid axon Li also cannot substitute for Na in driving the exchanger[19].

Figure 2*a* shows a similar experiment in which K completely replaced Na. Like the Li case, there was an excess of inward light-sensitive current compared with choline replacement that could only be attributed to K. The small initial decline in current indicates that the conductance is somewhat less permeable to K than to Na, while the secondary decline again suggests a progressive reduction in the conductance. From the initial current reductions in choline and in K the permeability ratio K:Na was estimated to be about 0·6. Besides carrying current, external K also tended to reduce the light-sensitive conductance. Figure 2*b* shows that when 20 mM or 55 mM Na was replaced, the steady-state current was actually smaller in K than in choline, even though K could carry substantial current. This blocking action of K seems to arise from inhibition of the Na–Ca

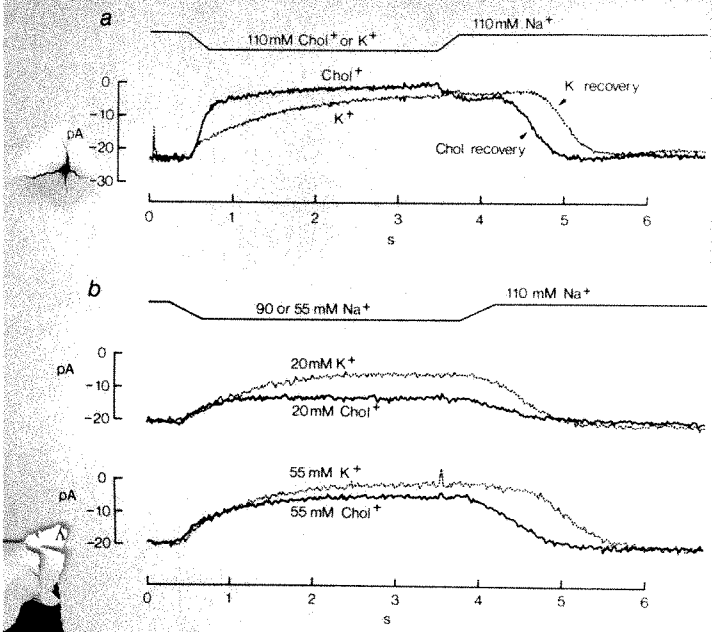

Fig. 2 Effect on rod light-sensitive current of the replacement of Na in Ringer's by K. 1 mM external Ca throughout. *a*, Complete replacement. *b*, Partial replacements. Two separate cells in *a* and *b*. The junction currents are already subtracted in each trace. All other ionic concentrations are the same as in Fig. 1 (including the extra 2.5 mM K). In *a*, the choline record is averaged from the differences between two dark and two light trials (alternated) while the K record is averaged from the differences between four dark and four light trials. In *b*, each of the choline and K records is averaged from the difference between two dark and two light trials. Small spikes in lower records of *b* are from incomplete subtraction of valve movement artefacts. Temperature 24.5 °C in both cases.

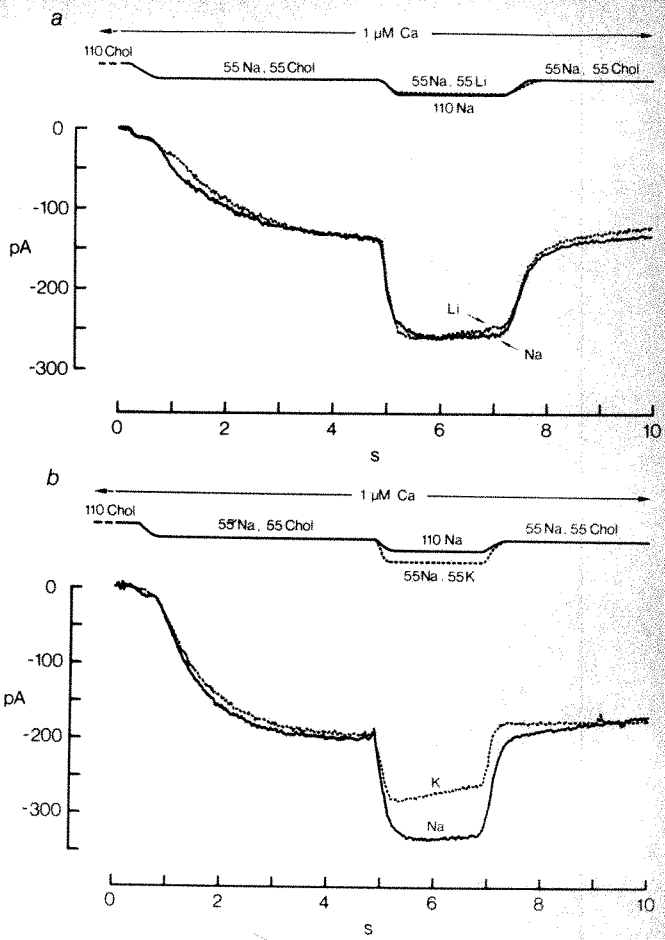

Fig. 3 Comparison of light-sensitive currents carried by Na, Li and K after the conductance was increased or 'primed' by a solution containing 55 mM Na, 55 mM choline and 1 μM Ca. Two separate cells in *a* and *b*. Junction currents, shown magnified above the light-sensitive currents, indicate the time courses of solution changes. The junction currents are already subtracted in each trace. All traces are from single trials. In addition to Na, choline, Li and K in various isotonic substitutions, the buffered 1 μM Ca solutions contained 2.5 mM K, 1.5 mM Mg, 0.093 mM Ca, 2 mM Mg-EDTA, 5 mM TMA-HEPES, 5 mM dextrose and were buffered to *p*H 7.6 (see ref. 14 for Ca buffering).

exchanger, as suggested by the increased delay in recovery after high K exposure (Fig. 2*b*). Indeed, the recovery after 55 mM Na, 55 mM K was as much delayed as that after 0 Na, 110 mM choline (see Fig. 2*a*), when the Na-dependent Ca efflux is presumably fully inhibited. Part of this K inhibition is probably due to a membrane depolarization effect on the exchanger, resulting from high K leaking into the pipette and affecting the inner segment, but there may also be a direct inhibition by K on the exchanger.

It has previously been shown that low external Ca substantially increases the light-sensitive current in rods[7,13,14], apparently by reducing internal free Ca[14]. This provides a more striking way to demonstrate passage of Li and K through the conductance. In Fig. 3*a* and *b* the outer segment was initially exposed to a 'priming' solution containing 55 mM Na, 55 mM choline and 1 μM Ca[14], which caused the light-sensitive current to climb slowly to a high level. At the plateau level an additional 55 mM Na, Li or K was added and the resulting current increases were compared. From the slopes or initial peaks of the current increases, the Li:Na permeability ratio was found to be near unity and K:Na was about 0.7, both similar to the estimates obtained from 1 mM Ca experiments. The fact that the additional 55 mM Na caused rather little slow secondary increase in current after the initial jump also suggested that the conductance was near its maximum in the 55 mM Na, 1 μM Ca solution.

In the same manner Rb and Cs were found to go through the light-sensitive conductance (data not shown). The permeability ratio Rb:Na was ~0.4–0.5, and Cs:Na was ~0·2–0.3. In addition, Rb had an inhibitory action like K. Since the relative selectivity for monovalent cations seems to stay unchanged in normal and low Ca conditions, low Ca perhaps simply increases the effective number or fractional open time of the conductance sites.

We have also found that the divalent cations Ba and Sr go through the light-sensitive conductance in both normal and low Ca solutions. A large light-sensitive Ca current was similarly detected when the rod outer segment was exposed to isotonic Ca immediately after the 55 mM Na, 1 μM Ca priming solution mentioned above[14], though for reasons still not well understood no Ca current could be observed when Na in normal Ringer's was completely replaced by Ca. Ba and Sr generally have permeation properties similar to Ca[20]; it therefore seems most likely that Ca does go through the conductance in normal Ringer's. In physiological conditions such a Ca current is perhaps small relative to the Na current because of the large difference in their extracellular concentrations (1 mM versus 110 mM). A small but steady Ca influx through the light-sensitive conductance could, however, provide a simple replenishment mechanism for internal Ca, which otherwise would be gradually depleted by extrusion to the cell exterior in the presence of light[9,10].

The above experiments support and extend earlier observations that when external Ca is extremely low (≤1 μM), cations other than Na can go through the light-sensitive conductance[13,14,18,21,22]. They also underscore the key role of the Na–Ca exchanger in maintaining the open conductance and explain why earlier experiments with slower solution changes did not detect substantial ion movements besides Na in normal Ca conditions[13]. The relative abilities of Na and K to go through the conductance as measured above, together with estimates

of their internal concentrations in rods[23], are consistent with the reversal potential for the rod light response being at 0 to +10 mV[15–17].

The rapid perfusion method was developed jointly with Professor Alan Hodgkin and Drs Peter McNaughton and Brian Nunn. They have independently obtained similar results on monovalent cations and have also provided comments on this paper. We also thank Drs Denis Baylor, Malcolm Brodwick, Lee Moore and John Russell for comments and discussions. The work was supported by US National Eye Institute and the Retina Research Foundation, Houston, Texas.

Intracellular Na^+ activates a K^+ channel in mammalian cardiac cells

M. Kameyama*, M. Kakei, R. Sato, T. Shibasaki, H. Matsuda & H. Irisawa†

National Institute for Physiological Sciences, Myodaiji-cho, Okazaki 444, Japan

In a wide variety of cells, various intracellular agents, such as Ca^{2+} (refs 1, 2), ATP[3,4] and cyclic nucleotides[5,6], regulate ionic conductances of the membrane. In cardiac cells, the intracellular Na^+ concentration ($[Na^+]_i$) frequently increases when a disturbance occurs in the electrogenic Na–K pump activity or the Na–Ca exchange mechanism. We have investigated a possible role of $[Na^+]_i$ in controlling ion channels by using a patch-clamp method[7], and have found a K^+ channel that is gated by $[Na^+]_i$ >20 mM, but not by the intracellular Ca^{2+} concentration ($\sim 10^{-4}$ M). We report here that the channel has a unitary conductance of 207 ± 19 pS($n = 16$) with K^+ concentrations of 150 mM outside and 49 mM inside, and shows no detectable voltage-dependent kinetics. The Na^+-activated K^+ channel represents a novel class of ionic channel.

In our experiments we used guinea pig ventricular single myocytes, dissociated by treatment with collagenase[8,9] (0.04%; Sigma type I). In the inside-out patch clamp experiments, at least three types of single-channel activities were observed with a pipette solution containing 150 mM KCl. One type of channel was identified as the inward rectifier K^+ channel[10–12] as it had a slope conductance (γ) of 32 pS, a reversal potential (25–30 mV) near the K^+ equilibrium potential (E_K) of 29 mV, and a mean open time of 200–250 ms at −40 mV (Fig. 1*ai*). The opening probability of the channel decreased with hyperpolarization. For the second type of channel, γ was 94 pS (Fig. 1*aii*) and there was little voltage dependency in the opening probability. The reversal potential of this channel was 30 mV, which was also close to E_K. The channel opening was blocked by 2 mM ATP inside the membrane. Thus, this channel is identical to the ATP-sensitive K^+ channel reported previously[4]. The third type of channel activity (Fig. 1*aiii*), however, has not been described previously; the γ for this channel was 220 pS (range 179–240 pS) in the potential range −60 mV to 0 mV. The reversal potential was 28 mV (Fig. 1*b*; mean = 28.7 ± 5.5 mV, $n = 12$), which is very close to E_K. With 50 mM K^+ and 100 mM Na^+ in the pipette, γ was 77 pS ($n = 3$) and the reversal potential was 1 mV, suggesting a 58 mV change for a 10-fold change in external K^+ concentration. Therefore, we conclude that this channel is selective for K^+. The slope conductance decreased at potentials more positive than 20 mV with 150 mM K^+ in the pipette (Fig. 1*b*), indicating an inward rectification of the single-channel current. Opening of the channel was usually accompanied by closures of short duration, which yielded bursts of openings (Fig. 1*aiii*). With 100 mM Na^+ on the inner side of the membrane, long intervals between bursts occurred only rarely. Therefore, the mean open and closed times were obtained from the arithmetical mean of the open or closed times. The mean open and closed times were 8.4 ± 2.0 ms and 6.5 ± 3.5 ms ($n = 4$), respectively, at 0 mV. The opening of the channel was unaffected by 2 mM ATP on the inner surface of the membrane. The probability of opening (P) was 0.49–0.54 and showed little voltage dependency at potentials between −40 mV and +20 mV (Fig. 1*c*). Thus, this type of K^+ channel differs from both the inward rectifier channel and the ATP-sensitive K^+ channel in single-channel conductance, mean open time and ATP sensitivity.

The value of P was found to depend on $[Na^+]_i$. Figure 2*a* shows that the activity of the channel was almost negligible in Na^+-free bathing solution (substituted by $Tris^+$); activity appeared only after the bath was perfused with 50 mM Na^+. We obtained similar results in eight other patches using $Tris^+$ or $choline^+$ as a Na^+ substitute. In contrast, $[Ca^{2+}]_i$ of 10^{-4} M failed to activate the channel (Fig. 2*b*). In this patch, we observed two channels after activation with 100 mM Na^+. Even when the channel was activated by Na^+, increasing $[Ca^{2+}]_i$ to 10^{-5} M had no significant effect on P. The inability of Ca^{2+} to activate the channel was confirmed in three other patches. Figure 3 shows the dose–response relationship of $[Na^+]_i$ to P for five patches. The channel was activated at about 20 mM, and P was 0.55 ± 0.10 ($n = 7$) at 100 mM $[Na^+]_i$. For a kinetic analysis, we considered, as a first approximation, a kinetic scheme having one open state and two closed states:

$$\text{open} \underset{\beta_1}{\overset{\alpha_1}{\rightleftharpoons}} \text{closed} \underset{\beta_2}{\overset{\alpha_2}{\rightleftharpoons}} \text{closed}$$

The transition rate constants (s^{-1}), calculated from the exponential distributions of the open and closed times[10] for a particular case with 50 mM K^+ in the pipette at −40 mV, were: $\alpha_1 = 422$, $\beta_1 = 398$, $\alpha_2 = 14.2$ and $\beta_2 = 63.1$ ($t_o = 2.51$ ms, $t_f = 2.05$ ms and $t_s = 81.3$ ms) with 30 mM Na^+ inside, and $\alpha_1 = 518$, $\beta_1 = 235$, $\alpha_2 = 44.3$ and $\beta_2 = 82.4$ ($t_o = 4.24$ ms, $t_f = 1.64$ ms and $t_s = 26.4$ ms) with 50 mM Na^+, where t_o, t_f and t_s are time constants of the open time distribution, and the fast and slow components of the closed time distribution, respectively. Thus, intracellular Na^+ affects all the rate constants. Among these effects, the predominant one might be an increase of α_2, which corresponds to a decrease in the interval between bursts. Within the pH range 8.0–6.5, P did not change significantly ($n = 3$). Li^+ (100 mM) could not substitute for Na^+ in the activation of the channel.

Further evidence for the activation of K^+ conductance by $[Na^+]_i$ was obtained in whole-cell clamp experiments. In Fig. 4,

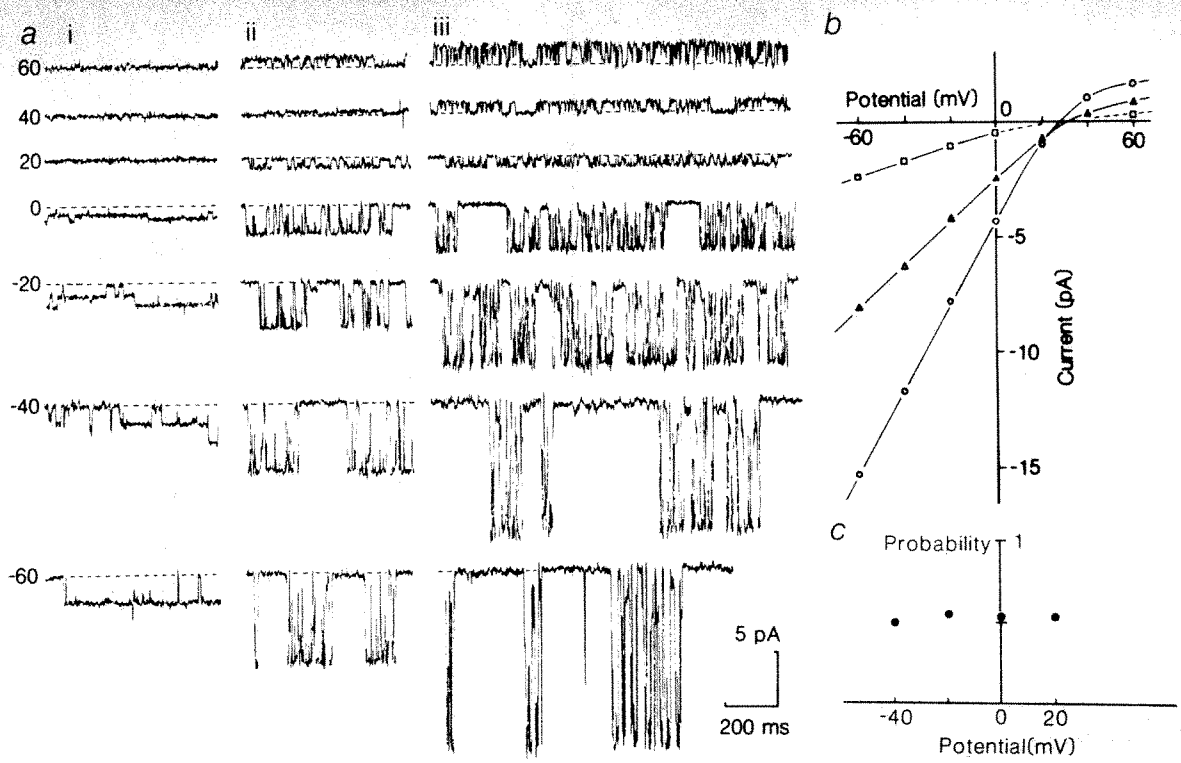

Fig. 1 Single-channel currents of three types of K^+ channel in inside-out patches. *a*, Current traces (recorded at potentials between −60 mV +60 mV) of the inward rectifier channel (i), ATP-sensitive channel (ii) and Na^+-activated K^+ channel (iii). *b*, Current–voltage relationship of the channels in *a*i (□), *a*ii (△) and *a*iii (○). The conductances measured at the linear part of the inward current were 32, 94 and 220 pS, respectively. *c*, Opening probability of the Na^+-activated channel in a different patch measured by integrating the current for at least 16 s. The compositions of the pipette and bath solutions were the same as for *a*iii. The pipette solution consisted of (in mM): KCl, 150; $CaCl_2$, 1.8; HEPES buffer, 5.0, *p*H 7.4. The bath solution for *a*i, *a*iii and *c* contained (in mM): KCl, 40; Na aspartate, 100; $MgCl_2$, 0.5; KH_2PO_4, 5.0; EGTA, 1.0; HEPES buffer, 5.0; glucose, 5.5; K_2-ATP, 2.0, with the *p*H adjusted to 7.4 by adding aspartic acid. In the patch illustrated in *a*ii, ATP was 0.5 mM; for the others the same concentration as in *a*i was used. Temperature of the perfusate was kept at 30–35 °C.

the inside of the cell was first dialysed with a Na^+-free solution, while perfusing the bath with Ca^{2+}-free Tyrode's solution. When the pipette solution was changed to 45 mM Na^+ solution, there was a shift in the current–voltage curve consistent with the activation of an outward current. The reversal potential of the activated conductance was −66, −67, −73 and −75 mV in four trials with three cells, consistent with E_K of −74 mV. The current induced by intracellular Na^+ shows an inward rectification around its reversal potential, but outwardly rectifies at potentials more positive than −24 mV. It is not clear whether this is due to a property of the Na^+-activated channel or an activation of other conductance systems.

These results indicate that intracellular Na^+ regulates the gating of a specific type of K^+ channel. The Na^+-activated K^+ channel can be characterized by its large conductance (207 pS), its inward rectifying property and its lack of appreciable voltage dependence of *P*. K^+ channels of very high conductance (~240 pS) have been reported in several tissues[13], most of which

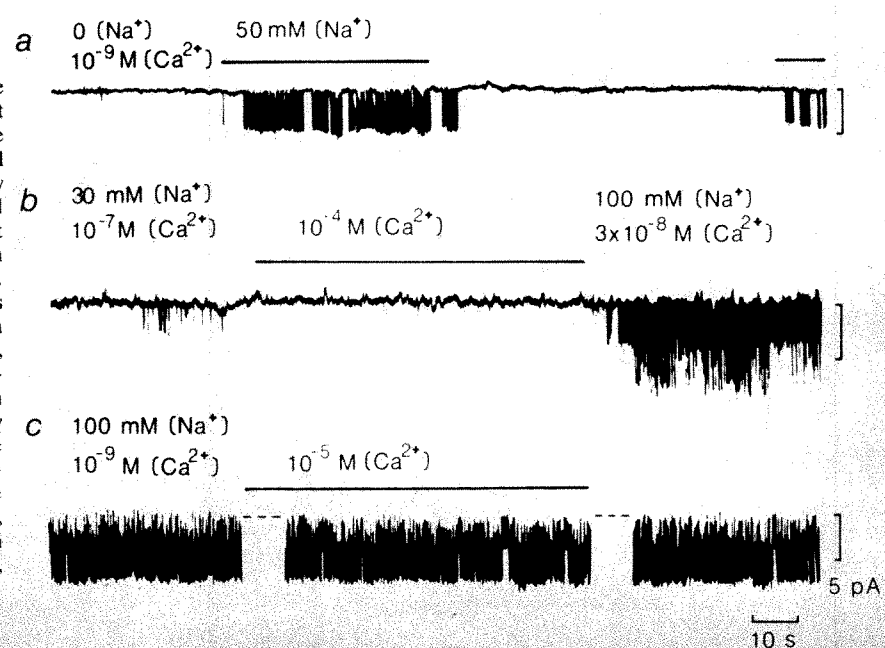

Fig. 2 *a*, Activating effect of $[Na^+]_i$ on the channel. Bath solutions with and without 50 mM Na^+ (0 $[Na^+]$ substituted by $Tris^+$) were alternatively perfused. Membrane potential was held at −30 mV. The opening probability (*P*) in 50 mM Na^+ was 0.54 and slightly reduced at the second trial. *b*, Lack of activating effect of $[Ca^{2+}]_i$ on the channel. The bath solution contained 30 mM Na^+ and 70 mM $Tris^+$. $[Ca^{2+}]_i$, buffered with Ca-EGTA buffer, was raised from 10^{-7} to 10^{-4} M, as calibrated by a Ca^{2+}-sensitive electrode (Orion Res. Inc., Cambridge, USA). Two channels were activated in the same patch by 100 mM Na^+, in which *P* was initially 0.23 and gradually increased to 0.48. *c*, Effect of $[Ca^{2+}]_i$ on the channel activated by 100 mM Na^+. Interruptions of the trace, lasting 3 min, represent the change of $[Ca^{2+}]_i$. The values of *P* before, during and after the elevation of $[Ca^{2+}]_i$ from 10^{-9} to 10^{-5} M were 0.60, 0.57 and 0.59, respectively.

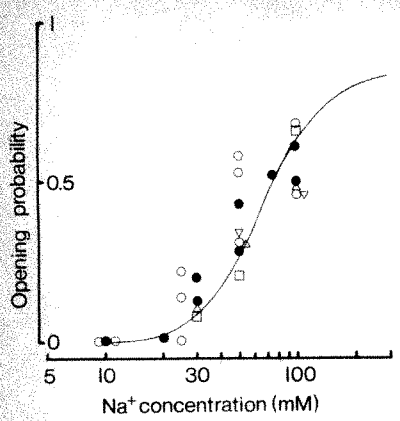

Fig. 3 Dose–response relationship between $[Na^+]_i$ and the opening probability of the channel. Measurements were performed in five different patches as indicated by the different symbols. A theoretical curve was drawn according to the following equation: $P = 0.85/1 + (K_D/Na_i)^n$, where K_D is a dissociation constant and n is Hill's coefficient. Using a least-squares fit, the values of K_D and n were found to be 66 mM and 2.8, respectively. The data indicated by solid circles were obtained in an opened cell-attached patch, where a part of the cell membrane was chemically skinned by treatment with saponin (10 mg ml^{-1}) while keeping the cell-attached patch intact.

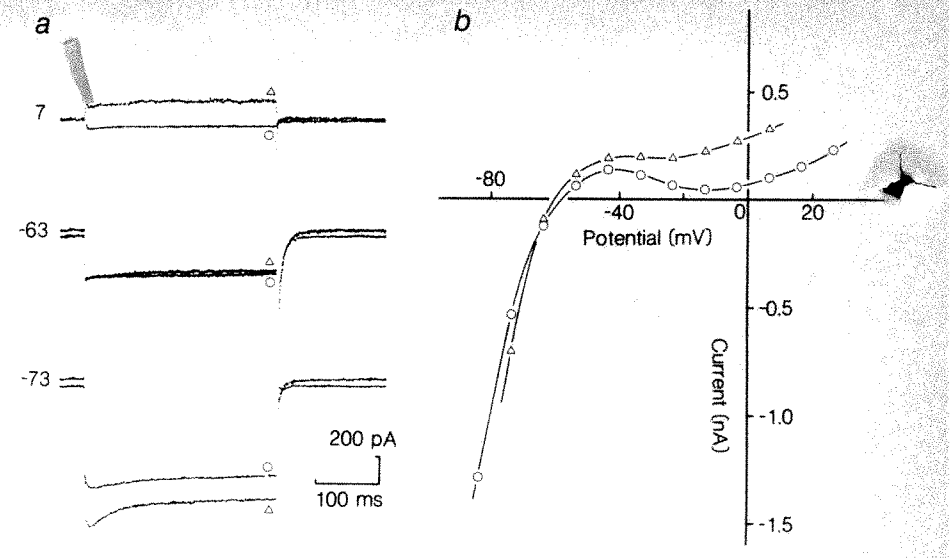

Fig. 4 Activation of a K^+ conductance by an increase in $[Na^+]_i$ in the whole-cell clamp. *a*, Current traces recorded with Na^+-free internal solution (○) containing (in mM): K-aspartate, 90; Tris-HCl, 50; K_2-ATP, 5; EGTA, 5, *p*H 7.4. Thereafter, 45 mM Tris-HCl was replaced with equimolar NaCl (△). The bath solution contained (in mM): NaCl, 143; KCl, 5.4; $MgCl_2$, 0.53; NaH_2PO_4, 0.33; glucose, 5.5; HEPES buffer, 5.0, *p*H 7.4. The holding potential was set at −43 mV to inactivate the Na^+ current. Test potentials are indicated at the left of each trace. *b*, Current–voltage relationship for the cell in *a*. The slope conductance at −67 mV was increased by 36%.

are Ca^{2+}-activated K^+ channels. It is of interest that the inward rectifier current in starfish egg cells requires intracellular Na^+ to be activated by hyperpolarization[14]. A similar mechanism might underlie the interaction of Na^+ with the channel reported here.

In normal cardiac cells, $[Na^+]_i$ has been reported to be <10 mM (refs 15, 16), a concentration which is balanced between the influx through Na^+ channels, the Na–Ca exchange mechanism and other passive leakage pathways, and active extrusion via the Na–K pump[17] as in other excitable cells. A prolonged failure of Na^+ pumping increases $[Na^+]_i$, resulting in a less efficient Ca^{2+} extrusion by the Na–Ca exchange, or even in a reversal of this mechanism due to a decrease in the Na^+ driving force[18,19]. Activation of K^+ conductance by the elevated $[Na^+]_i$ might improve the Ca^{2+} transport by opposing depolarization of the cells.

We thank Drs A. Noma and Y. Kurachi for helpful discussions, and Drs Y. Fukushima and M. E. Barish for their critical reviews of the manuscript. This work was supported by grants from the Ministry of Education, Science and Culture of Japan and the Ministry of Health and Welfare of Japan.

Adoptive transfer of myelin basic protein-sensitized T cells produces chronic relapsing demyelinating disease in mice

F. Mokhtarian*, D. E. McFarlin* & C. S. Raine†

* The Neuroimmunology Branch, National Institute of Neurological and Communicative Disorders and Stroke, National Institutes of Health, Bethesda, Maryland 20205, USA
† Albert Einstein College of Medicine, 1300 Morris Park Avenue, New York, New York 10461, USA

The autoimmune disease of the central nervous system (CNS), experimental allergic encephalomyelitis (EAE), is induced by challenge of genetically susceptible animals with spinal cord homogenates or myelin basic protein (MBP)[1–4]. Chronic and relapsing forms of the disease have some similarities to human demyelinating disorders, namely, multiple sclerosis[3,5–7], and are of particular interest. EAE can be transferred passively with sensitized lymphoid cells into syngeneic animals[8] but transferred EAE has been believed to have limited relevance to human disease because it is usually monophasic and manifested by minimal demyelination[9]. We report here that a single transfer of MBP-sensitized lymph node cells or T cells, in the absence of a peripheral antigen depot, leads to both acute EAE with significant primary demyelination, and chronic relapsing disease with lesions typical of demyelination over a long period. These findings have major implications for the immunological mechanisms involved in experimental and human demyelinating diseases.

Guinea pig myelin basic protein (GPBP) was prepared by the method of Diebler *et al.*[10]. The purity of the preparation was established by polyacrylamide gel electrophoresis. Female SJL/J

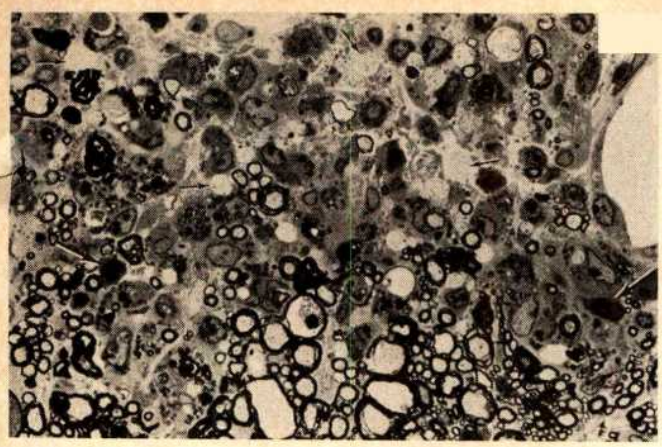

Fig. 1 Acute passively transferred EAE, 14 days post-transfer (1 μm epoxy sections stained with toluidine blue). Thoracic spinal cord. Higher magnification shows demyelinated axons (small arrows), large mononuclear cells containing myelin debris and at the edge of the lesion, polymorphonuclear leukocytes (large arrows). Some axonal damage and unaffected fibres are seen below. ×600.

mice, 6–10 weeks old, were injected subcutaneously at four sites, with 400 μg GPBP and 30 μg *Mycobacterium tuberculosis* in complete Freund's adjuvant[11]. Ten days later, the animals were killed; the draining lymph nodes were removed and passed through mesh in Hank's balanced salt solution (HBSS) to obtain a single cell suspension. Total lymph node cell (LNC) suspensions or B-cell-depleted suspensions, prepared by panning on anti-mouse IgG coated plates[12], were adjusted to 4×10^6 per ml and cultured in the presence of GPBP[11]. Four days later, the cells were removed and washed extensively. B-cell-depleted LNC were depleted further of adherent cells[13] by two successive incubations on Petri dishes precoated with fetal calf serum for 90 min at 37 °C. The desired numbers of LNC or T cells in 0.2 ml were inoculated into the tail vein of syngeneic recipients.

Animals were observed daily for clinical signs of EAE. The severity of the disease was graded on a scale of 1–5 (ref. 11). Relapses were only scored when a mouse developed a similar or more severe neurological deficit following a previous improvement. Routine histology was performed as described previously[4]. Selected animals between 14 days and 3 months after inoculation were perfused with 20 ml of 2.5% glutaraldehyde in PO_4 buffer and post-fixed in 1% osmium tetroxide. Blocks were dehydrated in ethyl alcohol and embedded in Epon 812. Epoxy sections 1 μm thick were stained with toluidine blue[14].

All recipients of $2–6\times10^7$ LNC or T cells developed clinical and histological signs of acute EAE 7–10 days after inoculation (Table 1, expts 1, 2). A few recipients of 7×10^6 cells showed a delayed onset of clinical disease as late as 82 days after transfer.

Approximately 20% of mice receiving 6×10^7 LNC died. After 2 weeks, the remaining mice with acute EAE either stabilized clinically, or gradually recovered with residual signs. At this time, some mice were killed for pathological examination and others were maintained for long-term clinical observations. Morphologically, the CNS of mice with acute disease showed perivascular inflammatory infiltrates in the meninges and parenchyma. The latter contained large lesions consisting of a primary wave of polymorphonuclear leukocytes which was followed by mononuclear cells. There was widespread loss of myelin but remarkable sparing of axons throughout the CNS, particularly in the subpial portion of spinal cord (Fig. 1); axonal degeneration was occasionally observed.

In five consecutive experiments, every mouse which recovered after the acute attack developed chronic relapsing disease. This usually began 30 days after the initial attack. After each relapse, the animals' conditions improved, but never returned to normal and with time there was progressive deterioration. Two representative experiments are shown in Table 1. In all studies, the potency of the adoptive transfer of chronic relapsing EAE, as judged by the number of relapses, the interval between relapses, clinical severity at the end of each attack and pathology was proportional to the number of LNC or T cells transferred.

Mice with chronic disease showed large lesions (Fig. 2) which were gliotic and contained inflammatory infiltrates consisting of a few polymorphonuclear leukocytes, many lymphocytes and macrophages. Although some axonal depletion was found, primary demyelination with sparing of axons was always evident and CNS remyelination was common (Fig. 3). The optic nerves were severely affected and dense collections of inflammatory cells were found within the angus of the lateral ventricles.

Chronic relapsing EAE has been induced in guinea pigs[2,3] and mice[4] by subcutaneous inoculation of CNS homogenates. Immunization with MBP may lead to relapsing disease in

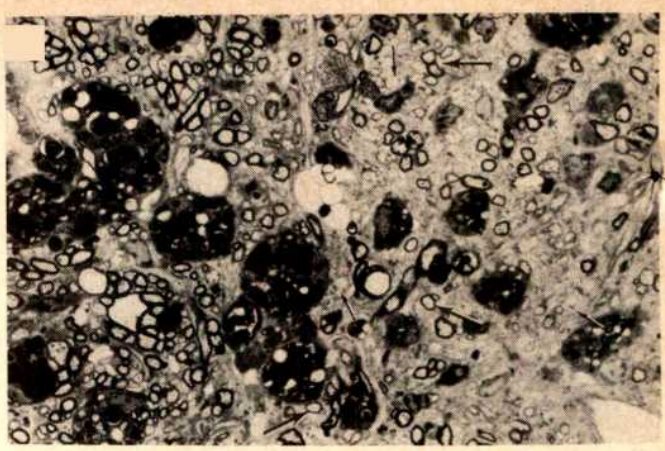

Fig. 3 Chronic relapsing EAE, 3 months post-transfer. At the edge of a chronic lesion, demyelinated axons (small arrows) and remyelinated axons (large arrows) can be seen. Towards the more normal white matter to the left, myelin degradation by large macrophages is apparent. ×600.

rats[15,16] and mice[17]. Injection of galactocerebroside with MBP augmented the level of demyelination observed in guinea pigs[18], and contamination of MBP preparations with lipid components has been reported[19]. These observations raise the possibility that trace amounts of lipids in our antigen preparation could contribute to the recurrent disease. Although this cannot be excluded, we believe it is unlikely because MBP prepared by the method used in this study does not produce demyelinating disease in guinea pigs.

Only acute EAE has been transferred to naive recipients either by sensitized lymphoid cells[8,11-16,20-23] or by T-cell lines[24]. Previously it was shown that the cells responsible for the transfer of acute murine EAE are Lyt-1$^+$2$^-$ T cells[11]. Recent work suggests that this subset of lymphocytes recognizes antigen in conjunction with class II molecules of the major histocompatibility complex (MHC). Although the reactive cells are directed at MBP, it is believed mostly to be localized in the major dense line of the myelin membrane[25] and therefore inaccessible to normal immune surveillance. Thus, reaction between MBP and immune cells may occur at some site other than the myelin membrane. MBP released during myelin turnover may be processed and presented to reactive cells. Indeed, macrophages[26], endothelial cells within the CNS[26] and oligodendroglia[27] have been reported to bear class II MHC molecules and could present antigen to immune cells. MBP is detectable in the blood of most species[28] which may help maintain immunological tolerance[29]. If MBP enters the circulation via the vascular endothelial cells, the luminal surface of such cells may be a site for interaction between immune cells and MBP[30]. This could lead to inflammation and result in subsequent myelin breakdown through a by-stander effect[28,31].

The mechanisms responsible for relapsing demyelinating disease in the absence of injected antigen are not known. One possibility is that MBP in antigen presenting cells is transferred along with the immune T cells and stimulates immune reactivity already present, but our previous findings with radiolabelled MBP indicate that the amount transferred would be less than 50 ng per animal[11]. Further, T cells depleted of antigen presenting cells still produced the chronic disease (Table 1, expt 2). Another possibility is that the acute disease produced by transferred T lymphocytes causes release of myelin antigen(s). MBP released with other myelin components during tissue damage may be more immunogenic than soluble MBP, and lead to alternation between the diseased and tolerant states[29]. Such antigen could either induce an immune response in the recipient or lead to an expansion of transferred memory effector cells. Rats immunized with cells from effector T-cell lines obtained from MBP-primed animals developed acute EAE but recovered, although they continued to harbour anti-MBP memory T cells in the thymus for months after the cell transfer[32]. Finally it is also possible that the acute disease induces an immune response against components of myelin other than MBP. Identification of the pathogenetic mechanisms responsible for the chronic autoimmune disease are of considerable importance because similar processes could occur in human demyelinating disorders.

Phagocytosing macrophages exclude proteins from the zones of contact with opsonized targets

Samuel D. Wright & Samuel C. Silverstein

Laboratory of Cellular Physiology and Immunology,
The Rockefeller University, New York, New York 10021, USA

During receptor-mediated phagocytosis, macrophages release toxic molecules such as hydrogen peroxide which enable them[1] to kill antibody-coated tumour cells[2] and parasites[3], too large to consume. Previous workers observed that while peroxide was clearly responsible for cytolysis of certain antibody-coated tumour cells[2,4,5], extracellular catalase was unable to inhibit this cytolysis, and they suggested that macrophages secrete peroxide into a protected cleft between the phagocyte and target. We have tested this and report here that the space beneath macrophages spread on glass surfaces is accessible to proteins with a molecular weight (MW) as large as 200,000 but the space beneath macrophages plated on glass surfaces coated with phagocytosis-promoting ligands is impermeable to proteins as small as 50,000 MW. It appears indeed that macrophages form a protein-tight seal at the periphery of their contact with ligand-coated surfaces and thereby create a closed compartment between the cell and the target.

To examine the ability of soluble proteins to permeate the zone of contact between a macrophage and a ligand-coated target, glass slides were coated with dinitrophenol (DNP)[6] and then with a monoclonal IgM anti-DNP antibody to give a IgM-coated surface (Fig. 1). IgM is not recognized by receptors on the macrophage, and therefore they spread on these surfaces as they would on glass or plastic. The purpose of the IgM-coated surfaces to provide binding sites for fluoresceinated anti-IgM antibodies. In parallel experiments, we incubated the DNP surfaces with a mixture of IgG–anti-DNP and IgM–anti-DNP (Fig. 1). The Fc domain of IgG is recognized by Fc receptors on macrophages, thus when the cells settle on such IgG-bearing surfaces they produce hydrogen peroxide[1] and spread extensively as though in an attempt to phagocytose the slide.

Human monocytes cultured for 4–12 days in Teflon beakers[7] were allowed to adhere to one of these ligand-coated surfaces. They were then incubated at 20 °C for 1.5 h with fluoresceinated anti-IgM, washed, fixed, and viewed with a fluorescence microscope. This antibody binds uniformly to IgM-coated substrates, even directly under the macrophage (Fig. 2*c*) and indicates that the space between the undersurface of adherent macrophages and the substrate is accessible to soluble proteins. In contrast, on IgG + IgM-coated surfaces, the fluoresceinated anti-IgM is excluded from the zone between the phagocyte and the substrate leaving 'black holes' in the fluorescent surface that correspond closely to the margins of the spread macrophage (Fig. 2*a*). This suggests that during phagocytosis, macrophages make a tight seal against the target surface that excludes soluble protein.

We have done several experiments to eliminate alternative explanations of these observations. The exclusion of fluoresceinated anti-IgM from the space beneath a phagocyte on an IgG-coated surface is not a consequence of the greater spreading or the evolution of peroxide seen when macrophages interact with IgG. If cells are treated with the tumour promoter, phorbol myristate acetate (PMA), the cells spread extensively and evolve large amounts of peroxide[1,8]. However, PMA-treated cells do not exclude fluoresceinated anti-IgM from their regions of contact with control IgM-coated surfaces (data not shown). Further, neither phagocytes nor their secretion products quench the antibody fluorescence because, when fluoresceinated anti-IgM is added to the IgG + IgM-coated surface before the cells are plated, the surface remains uniformly fluorescent. Finally, the cells do not consume or destroy the antigens recognized by the fluorescent antibody. When cells that had formed black holes are permeabilized with 1% Triton X-100 (in phosphate-buffered saline, 10 min, 5 °C), the IgM underlying the former holes can be stained with fluorescent antibody (data not shown).

We have confirmed our observations using electron microscopy. For these studies, we used horseradish peroxidase-labelled IgG anti-IgM (HRP anti-IgM) instead of fluorescent antibody, and the HRP anti-IgM was visualized by staining with diaminobenzidine. Sections cut perpendicular to the substrate show that HRP anti-IgM readily penetrates beneath macrophages spread on IgM-coated surfaces (Fig. 3*a*), but HRP anti-IgM cannot penetrate beneath macrophages engaged in a 'phagocytic' interaction with IgG + IgM-coated surfaces (Fig. 3*b*). The penetration of HRP anti-IgM stops within 0.28 (±0.15) μm of the margin of the cell, in a zone where the plasma membrane appears tightly adherent to the substrate. The entire plasma membrane is not, however, tightly adhered to IgG + IgM-coated surfaces. The membrane underlying the central area of the macrophage resembles that of a macrophage spread on a control substrate with interspersed regions of close apposition and regions well separated from the substrate (Fig. 3). Thus, there exists an open space or compartment between the cell membrane and substrate that is inaccessible to external proteins.

The exclusion of protein from the macrophage–substrate interface is not a simple physical consequence of receptor–ligand bridging. Macrophages have receptors for the third component of complement, C3, that mediate binding but not phagocytosis

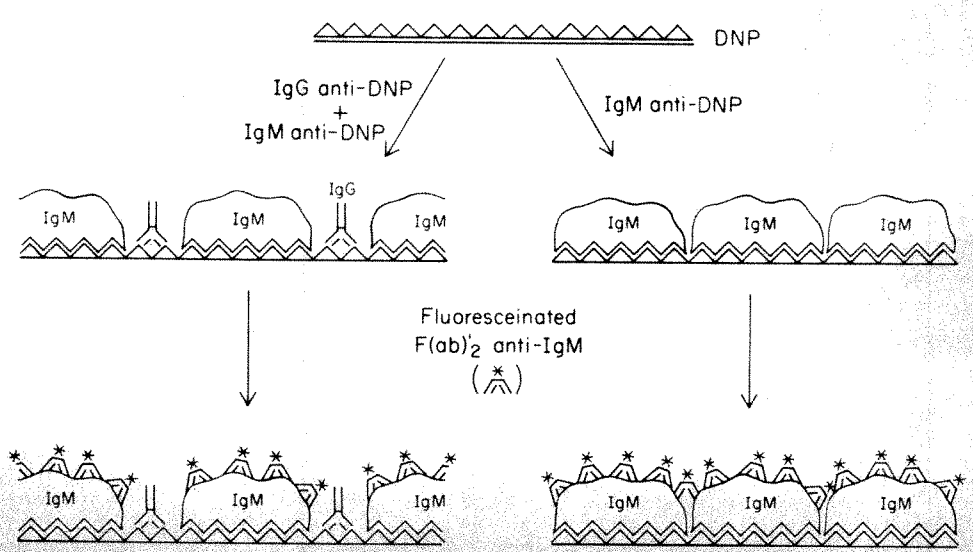

Fig. 1 Construction of ligand-coated surfaces. Masked slides (Carlson Scientific) were treated with poly-L-lysine then with 2,4-dinitrobenzene sulphonate to yield DNP-coated surfaces[6]. These surfaces were treated with 10 μl of murine monoclonal IgM anti-DNP (1:200 dilution of ascites fluid) with or without 10 μg ml^{-1} of affinity purified rabbit IgG anti-DNP (ref. 15) for 30 min at 20 °C. The surface was washed and macrophages were allowed to adhere to it. Fluoresceinated goat anti-IgM antibodies (IgG or the $F(ab')_2$, or Fab fragments (Cappell)) were diluted 1:100 in phosphate-buffered saline and added for 1.5 h at 20 °C. Fluoresceinated $F(ab')_2$ fragments are depicted here.

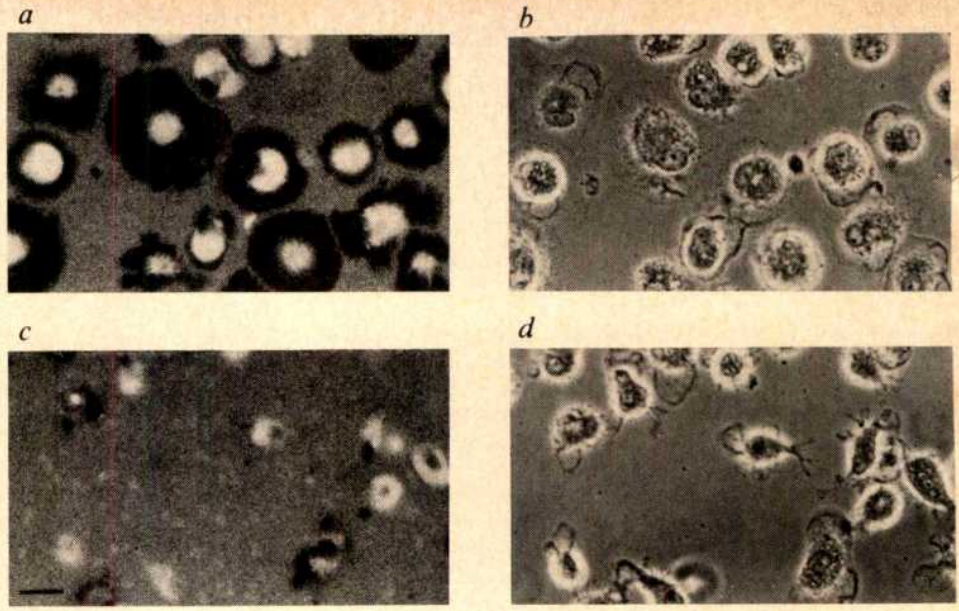

Fig. 2 Staining of ligand-coated substrates with fluoresceinated anti-IgM. Macrophages were cultured for 10 days in Teflon beakers, collected, then allowed to spread for 45 min at 37 °C on IgG + IgM-coated surfaces (*a*, *b*) or IgM-coated surfaces (*c*, *d*). The surfaces were then incubated for 1.5 h at 20 °C with a 1:100 dilution of fluoresceinated anti-IgM. Preparations were then washed, fixed in 3% formalin (diluted in phosphate-buffered saline) for 30 min at 20 °C, and photographed with a fluorescence microscope. The right-hand panels (*b*, *d*) are phase contrast photographs, and the left-hand panels (*a*, *c*) are fluorescent photographs of the same fields. Note that the IgM-coated surface underlying the cells is uniformly stained with the fluorescent antibody (*c*) but that cells spread on the IgG + IgM-coated surface protect the underlying antigens from binding the fluorescent anti-IgM (*a*). The centre of the cell appears bright owing to yellow autofluorescence that is easily distinguished from the green fluorescence of the antibody. In this experiment, fluoresceinated $F(ab')_2$ fragments of anti-IgM were used. Similar results were obtained using fluoresceinated Fab fragments or fluoresceinated whole IgG. Scale bar, 20 μm.

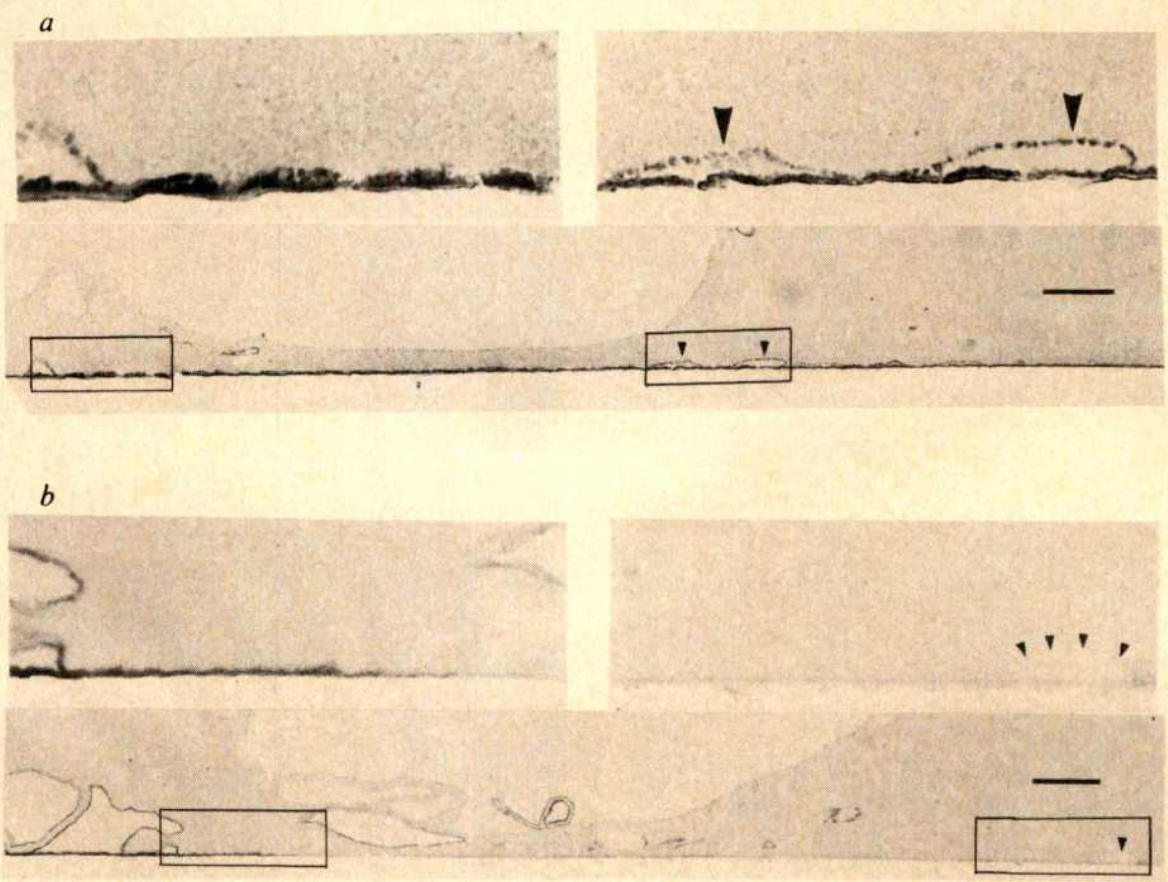

Fig. 3 Ultrastructural localization of horse radish peroxidase-labelled anti-IgM (HRP anti-IgM) on ligand-coated substrates. Macrophages were cultured for 8 days in Teflon beakers, collected, then allowed to spread for 45 min at 37 °C on IgM-coated surfaces (*a*) or IgG + IgM-coated surfaces (*b*). The surfaces were then incubated for 1.5 h at 20 °C with a 1:100 dilution of HRP anti-IgM, washed, then fixed for 1 h at 20 °C with 2.5% glutaraldehyde. HRP was stained using diaminobenzidine[16], the specimens were treated with 1% osmium tetroxide, and were then embedded in resin[17]. Sections cut perpendicular to the surface were viewed in an electron microscope without further staining. The electron-opaque reaction product generated by HRP is seen coating the entire IgM-coated surface, even directly under spread macrophages (*a*). In contrast, reaction product is not seen beneath cells spread on IgG + IgM-coated surfaces (*b*), even in locations where the plasma membrane rises from the substrate revealing an open space between the membrane and substrate (arrows). Boxed areas are shown in 3.5-fold enlargements. Scale bars, 0.1 μm.

of C3-coated erythrocytes[7]. We therefore constructed surfaces bearing C3 by incubating IgM-coated surfaces with a source of complement[9]. When macrophages spread on such surfaces C3 receptor activity is lost from the apical portion of the cell[7,10] because of diffusion of the receptors to the basal surface where they are 'trapped' by interaction with ligand[11]. However, despite this ligand–receptor interaction IgG anti-C3 can still penetrate readily beneath the macrophage. (To observe this, macrophages on C3-coated surfaces were cooled to 20 °C, then incubated for 45 min with murine IgG anti-C3, then for another 45 min with fluoresceinated Fab anti-IgG and examined by fluorescence microscopy.) In contrast, stimulated macrophages are able to phagocytose via their C3 receptors; the addition of 30 ng ml^{-1} PMA to macrophages cultures increases phagocytosis promoted by C3 receptors 10–50 fold[7]. Macrophages plated on a C3-coated surface in the presence of PMA exclude IgG anti-C3 from the interface with the substrate (data not shown). These experiments demonstrate that sealing of the contact zone between macrophage and target is not caused by receptor–ligand interaction alone but that cytoplasmic movements initiated by receptor–ligand interaction causes the sealing.

The spreading of cultured cells on glass or plastic has been likened to the cells' attempt to phagocytose a particle of infinite diameter. Here we show, however, that spreading and phagocytosis appear quite different. After spreading, the space between macrophage and substrate is freely accessible to proteins as large as 200,000 MW, but during a 'phagocytic' interaction with the substrate, proteins as small as 50,000 MW (Fab fragments of fluoresceinated anti-IgM) are excluded from the phagocyte–substrate interface. Thus it appears that the seal between macrophage and substrate is brought about by cellular movements characteristic of phagocytosis but not by the movements of spreading.

During phagocytosis, macrophages form the seal as a continuous rim at the leading edge of the advancing pseudopod, thus creating a closed compartment between phagocyte and target (Fig. 3). This observation is consistent with previous electron microscope studies which show the phagocyte's plasma membrane tightly appressed to the target at the leading edge and an open space between the macrophage and target at the base of the forming phagosome[11,12]. The presence of such a protected compartment has been predicted from experiments on the cytolytic action of phagocytes[2,4,5] and from studies of ligand-induced modulation of Fc receptors[13,14] and the data presented here provide evidence for its existence. We believe that this compartment is used to concentrate, protect and target toxic substances that may be specifically released into this space by the phagocyte.

We thank Dr V. Nussenzweig for the generous gift of monoclonal IgM anti-DNP, and Dr G. Kaplan for help with photography. This work was supported by USPHS grant CA 30198.

Separation of developmental compartments by a cell type with reduced junctional permeability

M. G. Blennerhassett & S. Caveney

Cell Sciences Laboratories, Department of Zoology, University of Western Ontario, London, Ontario, Canada N6A 5B7

Two recent reports[1,2] have suggested that the junctional membrane of the cells located at compartment boundaries in developing insect epithelia, although permeable to inorganic ions[3,4], prevents the cell-to-cell transfer of the fluorescent tracer Lucifer yellow (LY). However, cells within a compartment are linked by junctions permeable to both inorganic ions and organic tracers[1–5]. These findings imply that junctional communication is important in tissue development and that spatial selectivity may allow developmental autonomy in nearby compartments. The observation that LY was occasionally seen to pass across the segment border of the milkweed bug *Oncopeltus fasciatus*[1] suggested to us that the permeability of the junctions of the segment border may be locally controlled. We report here that the selectivity in the junctional channels at compartment boundaries in this insect is variable and under the control of a discrete population of border cells. The extent to which these cells reduce the rate of tracer passage across the compartment boundary relative to that within the compartment is influenced by the culture medium in which the tissue is placed.

Pieces of integument, containing three segment borders, were dissected from the dorsal abdominal wall of fourth instar nymphs of the mutant strain *cb;wb* (ref. 6). Epidermis of this stage was selected over that of the fifth instar studied previously[1] because the cuticle is smoother at the segment borders and allows greater cellular detail to be seen. The preparation was clamped in a culture dish containing one of three bathing media (Table 1), and examined at ×40 objective magnification by phase-epifluorescence[7]. Routine methods were used to microinject dye into cells by iontophoresis[8].

The transverse border of each segment is usually marked by the presence of several rows of elongated cells ('border cells') with their long axes parallel to the border[9]. The pigmentation and clonal origin of these cells suggest that they have a common lineage with the more posterior segment, that is, they are at the leading edge of the segment[9]. The border cells confront the most posterior cells of the segment ahead. Both these posterior cells and the general cells of the posterior segment are normal in shape (regular polygons) (Figs 1–3).

Three fluorescent dyes were used to probe the junctional permeability of the border cells: Lucifer yellow (LY, molecular weight 457), 6-carboxyfluorescein (CF, molecular weight 376), and lissamine rhodamine B (LRB, molecular weight 559). Dye was injected into a normally shaped cell one or two cells distant from the strip of border cells. The extent of dye spread was recorded photographically (Figs 1, 2), while the rate of dye passage in the cell sheet was determined from spreads videotaped during dye injection[10,11].

The cell-to-cell spread of all three dyes was radially asymmetrical (Fig. 1), as their passage into and across the strip of border cells was always retarded. In a typical LY spread (Fig. 1*a*), appreciable amounts of the dye passed into the cells next to the source cell within 3 s, and into the border cells within 10 s. A drop in fluorescence intensity coincided with the margins of the border cells. Within 30 s the dye had passed across the border into the normally shaped cells of the next segment, to image cell detail such as nuclei, vacuoles and cell margins. A dead cell in the recipient segment was silhouetted by the dye diffusing around it. This was observed irrespective of whether the source cell was anterior or posterior to the border. The 'texture' to the dye spread is proof that the dye passed from cell to cell and was not due to scattered light or to the dye passing between the cells and the underlying cuticle. The general

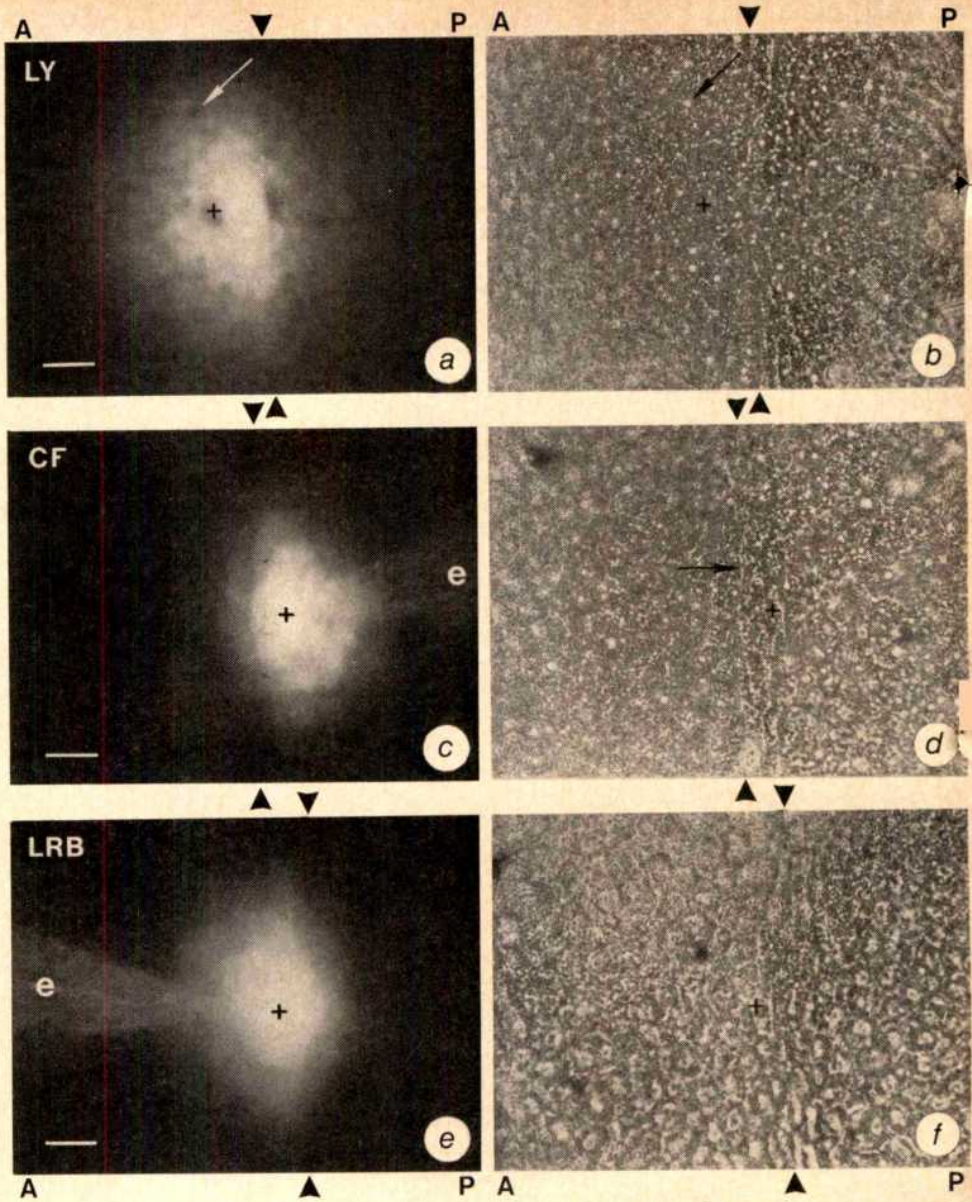

Fig. 1 Fluorescent tracers microinjected into epidermal cells near the segment border pass across it, although a drop in fluorescence occurs in this region. Left: record of three different fluorescent tracers spreading rapidly across the segment border. Right: the same preparations shown in phase contrast. The position of the border is marked by the arrowheads above and beneath the micrographs. A, anterior segment; P, posterior segment. Scale bar, 25 μm. *a*, Lucifer yellow (LY) was injected into a cell (+) anterior to the segment border for 30 s, the electrode was then removed and the extent of dye spread photographed immediately (60 s exposure). The spread of dye is impeded by the border. The appearance of the cells, imaged by dye localized in their nuclear regions, suggests that the border cells were not particularly elongated in this preparation. The source cell was damaged during electrode removal and failed to retain the dye. The dark area just across the border from the injection site is a dead cell imaged by the dye that diffused around it. *b*, Phase-contrast appearance of *a*. The most posterior cells of one segment are more opaque than the anterior cells of the adjacent segment. In some cells of preparations such as this one, the presence of small vesicles that exclude dye (diagonal arrow in *a* and *b*) allow the micrograph pairs to be matched up independently of the cell margins, which are often obscure. *c*, Carboxyfluorescein (CF) injected for 20 s, into a cell (+) posterior to the segment border, and the extent of its spread photographed (7 s exposure). CF has crossed the border within 30 s of the start of injection. This dye fills the individual cells more uniformly than does LY (*a*). The tip of the electrode (e) was left in the source cell after the period of dye injection was over. *d*, Phase-contrast appearance of *c*. In the centre of the micrograph the position of the segment boundary is marked by a thin intercellular space (horizontal arrow). Cell margins, although generally difficult to discern here, are seen as step-like drops in fluorescence in *c*. *e*, Lissamine rhodamine B (LRB) injected continuously for 120 s into a cell (+) in the anterior compartment and the spread photographed (12 s exposure) with the electrode (e) still inside the source cell. This dye was the slowest to image cell detail across the border. *f*, Phase-contrast appearance of *e*.

Methods: Cell preparations were excised from fourth instar nymphs in the middle of the instar, placed in medium 3 (ref. 15) and used within 60 min of dissection. Dye was iontophoresed from an electrode (200-ms current pulses, 1 per s; strength in *a*, 60 nA; in *c* and *e*, 6 nA) inserted into a normally shaped cell (the source cell) one or two cells distant from the border cell strip. Placing the electrode in this position prevented the tip from crossing the border accidentally, either during its insertion into the source cell or due to any slight electrode drift during injection. Both could give a false positive for the dye passage across the border. The source cell was close enough to the border to allow dye to bank up against it, and passage across it to be detected. The entry of the dye electrode into the source cell was timed from the moment its membrane potential was recorded on the chart recorder. Criteria for a successful dye spread were a stable membrane potential, between 26 and 35 mV during the period of dye injection, and the presence of cell detail in the fluorescence image.

features of the cell-to-cell passage of CF and LRB both within and between segments were the same as those for LY, although the rates differed. The spread of LRB was considerably slower than that of the other two dyes, as has been noted in another insect epidermis[11].

We noticed also that the rate of dye spread was considerably influenced by the medium in which the tissue was placed (Table 1). In some media, such as that used for the preparations shown in Fig. 1, the border offers little resistance to dye spread; in others, dye passage is almost totally blocked in the border region. This observation suggests that the cells at the segment border can regulate the segment-to-segment passage of cytoplasmic molecules, but does not indicate whether the asymmetrical spread of dye is the result of tighter packing of border cells (since dye spreads more rapidly within cells than between cells) or whether the permeability of the junctional channels in the border region is set at a different level from that elsewhere in the segment. To show that the altered shape of these cells is not the sole cause of the impeded dye spread, some preparations were placed in medium that depressed segment-to-segment dye coupling, a cell posterior to the border cells was injected with CF, and the extent of its spread photographed. The procedure was repeated on a cell anterior to the border, directly opposite the first cell. The result (Fig. 2) has two main features. First, dye spread is virtually blocked in the border region in both cases (in contrast to Fig. 1). It is unlikely that this could be due to changes in cell packing. Second, the lines along which the dye movement is restricted are not the same, but coincide instead

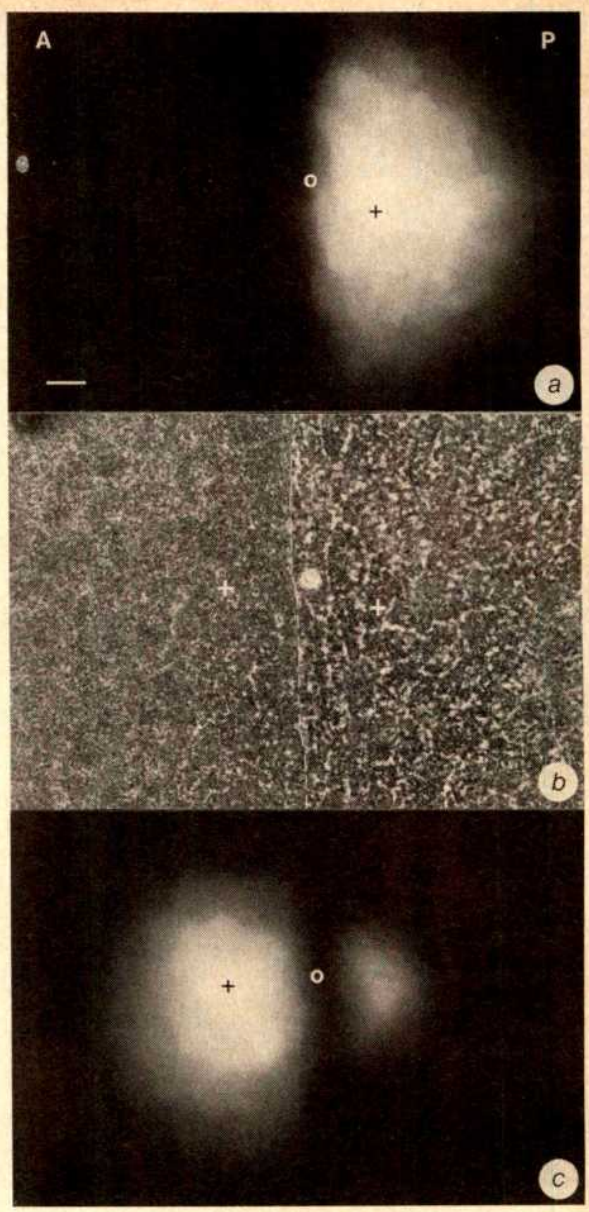

Fig. 2 When tracer was injected into a cell near the segment border in preparations immersed in medium 1 of Table 1, its spread was blocked along a line parallel to the segment border. Dye injected into the anterior segment was blocked at the border while that injected posterior to it was blocked at a line that did not coincide with the segment border, but was separated from it by a strip of cells. The junctional permeability of this border strip of cells appears to be regulated independently, since dye moved rapidly among cells within a segment. CF was injected (200-ms pulses of 60 nA, 1 per s) into cells labelled +. A, anterior segment; P, posterior segment. Scale bars, 10 μm. *a*, CF injected into a cell posterior to the segment border for 9 s and the extent of dye spread photographed 22 s later (4 s exposure) with the electrode removed. The dye spread in a radially asymmetrical fashion and was blocked in its passage along a line passing through a marker particle (white circle, see *b*). Contrast the shape of this spread with that in Fig. 1c, where the spread of dye is only slightly retarded in the border region. *b*, Phase-contrast view of the cells shown in *a* and *c*. The more opaque cells of the anterior segment are distinguishable from the clearer cells of the posterior segment; the position of the segment border is emphasized by the dashed white line. The refractile particle lying just to the right of the segment border serves as a reference for locating it in *a* and *c*. *c*, Dye injected for 8 s and its fluorescence photographed 23 s later (4 s exposure) with the electrode removed. Dye spread is asymmetrical with its movement strongly truncated at the segment border, just to the left of the marker particle (white circle). Residual fluoresence from the spread shown in *a* done 4.5 min earlier is seen to the right of the marker particle. A drop in tracer fluorescence at the border could be an artefact caused by a reduction in cell thickness or changes in the cuticle in this region. Histological sections, however, showed the integument to be flat and the cell and cuticle thickness to remain constant across the border in our fourth instar preparations. Since the fluorescence was viewed through the cuticle, it is also possible that a reduction in the light-transmitting properties of the cuticle might lower fluorescence at the border. Consequently, preparations injected with dye were then inverted and re-examined. With the cuticle removed from the light path, no change in the intensity and distribution of fluorescence was seen.

with the margin of the border cell population nearest the injection cell. In both cases, the dye spread one or two cell diameters towards the border before being stopped by the border cells, while at the same time spreading four to five cell diameters away from the border. Here, it appears that there is a separate population of border cells having greatly reduced junctional permeability.

The presence of a cell type with different junctional properties can also be demonstrated by injecting dye simultaneously into two cells, one on either side of the border (Fig. 3). A narrow strip of elongated cells, lying just posterior to the segment border, is revealed by its lower tracer permeability, despite a high concentration of dye potentially able to enter these cells from both sides. When a border cell identified in this way was subsequently injected with dye, it passed at best slowly and radially into the surrounding cells. No preferential movement of dye among the border cells was detected.

Although Warner and Lawrence[1] clearly demonstrated an alteration in the normal cell-to-cell diffusion of microinjected tracers at the compartment border, they did not explain how this was achieved. The data suggested, nevertheless, that reduced junctional permeability at the border results from the confrontation of the surfaces of cells belonging to different compartments. This implies that communication is reduced only at areas of membrane junctions connecting cells of adjacent compartments, but that it remains normal at junctions connecting border cells with other cells in the same compartment. However, this appears not to be the case. *In vitro*, reduced communication between compartments in the bug is due to the intervention of a discrete population of cells (located at the anterior margin of each segment) whose junctions in certain culture media all have reduced permeability. These cells communicate less not only with the cells of the compartment anterior to them, but also among themselves and with the general epidermis of their own

Table 1 Extent of cell-to-cell spread of three fluorescent tracers across the segment border

Tracer	No. of preparations tested	Appearance of individual dye spreads		
		a	*b*	*c*
Carboxyfluorescein	29	13 (1)	69 (1–3)	3 (3)
Lucifer yellow	10	0	25 (1–3)	8 (2, 3)
Lissamine rhodamine B	19	10 (1)	36 (1–3)	2 (3)

About equal numbers of spreads were prepared in which the source cell lay anterior or posterior to the border. No differences in dye spread were noted. *a*, Dye spread restricted to within one segment by border cells; *b*, dye spread into adjacent segment but impeded by border cells; *c*, dye spread minimally retarded by border cells. As we were concerned that the composition of the culture medium might influence junctional permeability, three media were tested. Each preparation was used in only one medium. Numbers in parentheses refer to the media in which a particular result was obtained. Medium 1 was TC 199 containing 10 mM PIPES buffer, medium 2 was leafhopper medium[14] and medium 3 was a *Drosophila* medium[15] lacking amino acids. The media contained 10% fetal calf serum and the *p*H was adjusted to 6.7 with NaOH. Of the three, medium 3 least retarded the movement of fluorescent tracer across the border. It also resembled most closely the blood of phytophagous hemiptera in its monovalent and divalent cation levels.

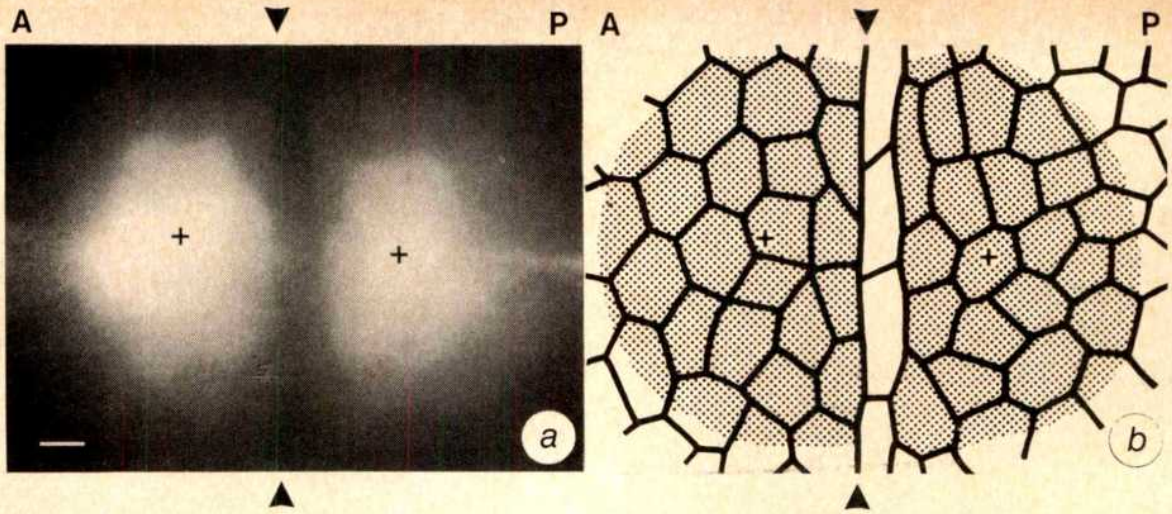

Fig. 3 The cell-to-cell spread of LRB injected into a cell on each side of the border simultaneously outlines a border strip of cells slow to receive the dye. The reduced permeability of these cells may explain how molecular interactions between compartments are limited. Arrowheads mark the position of the segment border. A, anterior segment; P, posterior segment. Scale bar, 10 μm. LRB was injected into the two cells (+) with 200-ms current pulses of 5 nA, 1 pulse per s. In *a*, the extent of spread of LRB was photographed between 20 and 30 s after injection (exposure time 10 s). In this preparation the border strip of cells only partially restricted the segment-to-segment spread of dye. While dye spread extensively among the cells of each segment, it was retarded sufficiently in the border region to outline the border cells. *b*, Margins of the cells seen in *a* drawn from their combined fluorescence and phase-contrast images, showing the extent of the dye spread (stippled areas) from the two injection sites. As in Fig. 2, the border strip (not stippled) appears to consist of a single row of cells.

compartment (similar to a mechanism that may exist at compartment boundaries in the *Drosophila* wing disc[2]). The ability of the border cell junctions to block selectively the passage of organic tracers in certain conditions *in vitro*[1,2] suggests that these cells may modulate the size range of molecules able to pass from segment to segment at different times in development.

Other distinct behaviours of the border cells include their rapid migration and proliferation during wound healing[12,13]. Their reduced junctional communication and characteristic behaviour may allow these cells to remain neutral in their gradient properties[12] and hence serve to establish and maintain discontinuity between the segmental compartments.

We thank Dr M. Locke for constructive comments on the manuscript and Rosemary Melchin for typing it. This work was supported by NSERC of Canada.

The heavy (H) and light (L) chains of antibodies consist of variable (V) and constant (C) regions. The V regions of the heavy and light chains form the antibody combining site[1,2]. To determine whether a V region could be functional when joined to a polypeptide other than its own C region, we constructed a chimaeric gene encoding the V region of a mouse heavy chain and the C region of a mouse κ light chain (V_HC_κ). The heavy-chain gene is derived from an A/J mouse hybridoma cell line 36-65 whose antibody product (γ1, κ) is specific for the hapten azophenylarsonate[3]. We report here that, when introduced into a mouse myeloma cell line, the chimaeric gene is expressed and a protein of the expected molecular weight is secreted into the medium. As light chains tend to dimerize[4,5] we expected that the V_HC_κ protein might associate with light chain from the cell line 36-65 to form an antibody-binding molecule. Affinity binding experiments and K_a determination indicate that this is the case. Dimers of this type offer a novel and interesting alternative to existing antibody-binding molecules.

Figure 1 shows the scheme used to construct two plasmids, ΔHpV and ΔHpVE, bearing the V_HC_κ chimaeric gene and the selectable marker Ecogpt[6,7]. Both ΔHpV and ΔHpVE contain the rearranged 36-65 V_H gene with its 5′ flanking sequence[8], and DNA encoding the C region of the κ light chain of the S107 BALB/c mouse myeloma cell line[9]. A chimaeric intron separates the V_H and C_κ genes; this intron includes the light chain transcriptional enhancer sequence (E_κ)[10,11] (V.T.O. and S.L.M., unpublished results) in ΔHpV, and both E_κ and E_H, the heavy chain transcriptional enhancer sequence[12–14], in ΔHpVE (Fig. 1).

ΔHpV and ΔHpVE were separately transfected into J558L BALB/c mouse myeloma cells by protoplast fusion[15] as described elsewhere[16]. (J558L is a variant of the J558 cell line[17] that synthesizes and secretes only a λ light chain but no heavy chain.) Transformants containing the Ecogpt gene were selected in medium containing mycophenolic acid[6,7]. Ten transformants from each of the two transfection experiments were analysed for production of V_HC_κ by immunoprecipitation with rabbit antiserum specific for the C region of mouse κ chain, and separately with rabbit anti-idiotype (Id) antiserum specific for

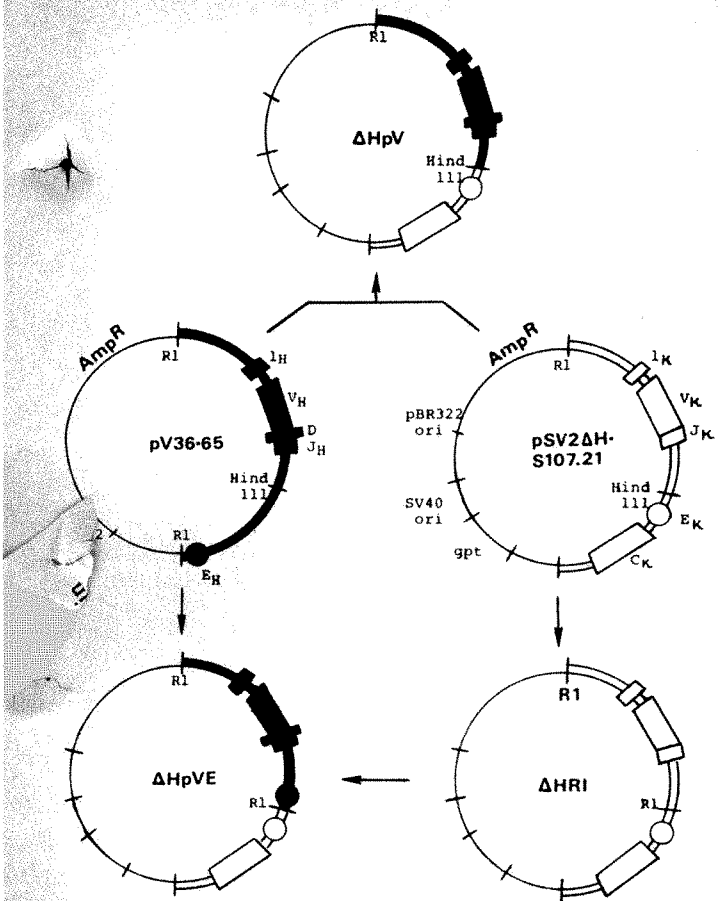

Fig. 1 Construction of V_HC_κ-containing plasmids. pV36-65 contains the 363-base pair (bp) rearranged V_H gene derived from the hybridoma cell line 36-65. This gene is flanked by 2.4 kilobase pairs (kbp) of upstream sequence and 2.1 kbp of downstream sequence terminating in the J_H–C_μ intron[8]. pSV2ΔHS107.21 was derived from pSV2-S107 (ref. 16) by elimination of one *Hin*dIII site. pSV2ΔHS107.21 contains the *Escherichia coli* xanthine–guanine phosphoribosyl transferase gene (*gpt*), and the entire rearranged genomic κ light-chain gene of the S107 myeloma cell line[9] including the leader (1_κ), V_κ and C_κ exons as well as flanking 5′ and 3′ sequences. The *gpt* gene confers on mammalian cells resistance to mycophenolic acid when xanthine is present in the medium[6,7]. The simian virus 40 (SV40) origin of DNA replication (ori) and early promoter are located 5′ to the *gpt* sequence. The S107 κ gene is oriented in the opposite direction to *gpt*. ΔHR1 was constructed from pSV2ΔHS107.21 by converting the *Hin*dIII site into an *Eco*RI site. To generate ΔHpV the *Eco*RI–*Hin*dIII fragment containing the rearranged V_H gene from pV36-65 was substituted for the *Eco*RI–*Hin*dIII fragment containing the rearranged V_κ gene in pSV2ΔHS107.21. To generate ΔHpVE the *Eco*RI–*Eco*RI fragment containing the rearranged V_H gene from pV36-65 was substituted for the *Eco*RI–*Eco*RI fragment containing the rearranged V_κ gene in ΔHR1. The heavy-chain exons and introns are represented by solid boxes and lines; the κ chain exons and introns are represented by open boxes and lines; the heavy-chain enhancer sequence (E_H)[12–14], and the κ chain enhancer sequence (E_κ)[10,11] (V.T.O. and S.L.M., unpublished results) are represented by a solid and an open circle, respectively. Plasmids are not drawn to scale.

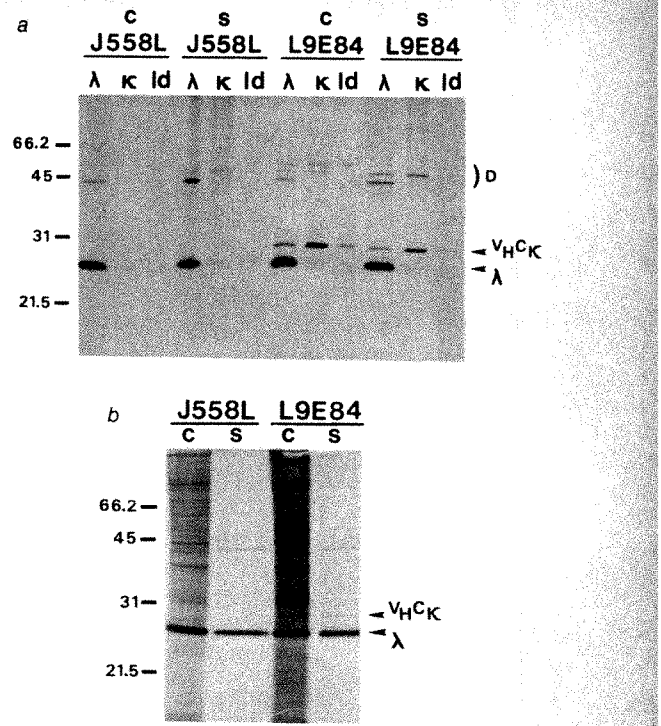

Fig. 2 Autoradiographs of SDS-polyacrylamide gels of cytoplasmic (c) and secreted (s) proteins. Cells were biosynthetically labelled with ^{35}S-methionine in methionine-free Dulbecco's modified Eagle's medium (Irvine Scientific, Santa Ana, California) for 1 h for cytoplasmic protein assay and 3 h for secreted protein assay. Cell extracts were in 0.5% Nonidet P-40 (NP40) containing 0.06 M iodoacetamide. Electrophoresis was in 12.5% SDS-polyacrylamide gels in non-reducing conditions. The positions of the molecular weight markers (Biorad) (in kilodaltons) are indicated; the positions of V_HC_κ and λ light chain are indicated by arrows. ***a***, Cytoplasmic and secreted proteins from J558L and from L9E84 cells were immunoprecipitated with rabbit anti-mouse antisera and *Staphyloccocus aureus*[26] (Staph A) and electrophoresed as described[27]. The antisera used are indicated above each lane. Rabbit anti-mouse κ was obtained from M. Potter under the auspices of NCI contract NO1-CB-25584. Rabbit anti-mouse α + λ (designated λ) was prepared in the laboratory of S.L.M. by L. A. Wims. Rabbit anti-Id antiserum was prepared by L. J. Wysocki. Dimers (D) are indicated. ***b***, Total cytoplasmic and secreted proteins from J558L and from L9E84 cells. Densitometer tracings of L9E84 lanes were done using a Quick Scan (Helena Laboratories). For quantitation, peaks from Xerox copies of the scans were cut out and weighed.

the V_H protein sequence[3,18]. Whereas 6 out of 10 ΔHpVE transformants produced a protein reactive with the anti-κ and anti-Id antisera, only one out of 10 ΔHpV transformants produced such a protein. The relative amounts of the chimaeric protein produced by ΔHpV and ΔHpVE transformants were not significantly different (not shown). The greater number of positive transformants obtained with ΔHpVE might reflect the presence of the heavy-chain enhancer in ΔHpVE.

The ΔHpV positive transformant (which was the first to be recovered) was subcloned in soft agarose[19,20], and one clone, L9E84, was selected for further studies. Figure 2*a* shows an immunoprecipitation analysis of biosynthetically labelled cells. A protein of the expected molecular weight (29,500) reactive with anti-κ and with anti-Id antisera is present in L9E84 but not in J558L cell extracts. Furthermore, this protein is secreted into the medium (Fig. 2*a*). Immunoprecipitation of V_HC_κ from L9E84 culture supernatant by anti-κ antiserum removed the species reactive with anti-Id antiserum (not shown). The V_HC_κ chimaeric protein can be differentiated from the J558L λ light chain by its lower mobility in SDS-polyacrylamide gels in non-reducing conditions (Fig. 2). The upper bands in Fig. 2*a* are probably covalent dimers (D); from the relative sizes of these putative dimers it seems that V_HC_κ can dimerize both with itself and with the J558L λ light chain.

The V_HC_κ chimaera comprises about 1% of the biosynthetically labelled L9E84 cell protein and is present in one-tenth the amount of J558L λ light chain, as determined by densitometer tracing of the autoradiogram shown in Fig. 2*b*.

Ascites from BALB/c mice injected intraperitoneally with L9E84 cells contains the chimaeric protein, as determined by radioimmunoassay. This assay measured the ability of the ascites fluid to compete with the ^{125}I-labelled idiotype-bearing molecule, 36-65 Fab, for the binding of rabbit anti-Id antiserum[3].

mRNA encoding the V_HC_κ protein in L9E84 cells was detected by Northern analysis (Fig. 3). An RNA species of the expected size, ~1.3 kilobases (kb), that hybridizes with an azophenylarsonate (Ars) idiotype probe (specific for the V_H sequence) and with a κ probe (specific for the C_κ sequence) is present in L9E84 but not in J558L cells. It is noteworthy that the chimaeric intron between V_H and C_κ is probably correctly spliced using the donor splice site from the heavy-chain gene and the acceptor splice site from the κ light-chain gene. Correct splicing of a chimaeric intron was observed previously[21].

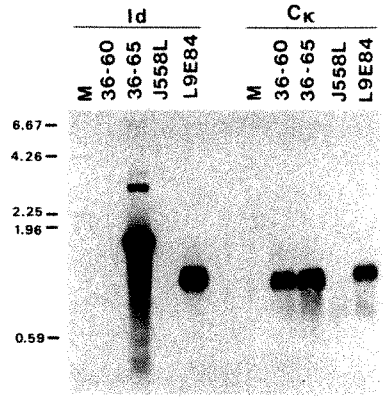

Fig. 3 Northern analysis of L9E84 and control cell RNA. Total cell RNA was prepared from culture cells as described elsewhere[28]. The RNA (6 μg per lane) was electrophoresed in duplicate in a 1.2% agarose gel in 10 mM Na-phosphate and transferred to nitrocellulose[29]. The nitrocellulose filter was cut in two and the RNA hybridized to nick-translated ^{32}P-labelled probes. One half was hybridized to a 133-bp V_H probe specific for the V_H gene encoding the anti-Ars idiotype-positive heavy chain[8,30], while the other was hybridized to a mouse C_κ region cDNA probe (obtained from A. Bothwell and D. Baltimore). The cell line from which the RNA was derived is indicated above each lane. 36-60 is an A/J-derived hybridoma which produces an antibody specific for Ars but devoid of the Ars cross-reactive idiotype[3], and uses an unrelated V_H gene. A ^{32}P-labelled *Hin*dIII digest of phage λ DNA was used as a molecular weight marker (M), and fragment sizes are indicated in kbp. The two halves of the nitrocellulose filter were reattached for autoradiography.

We wished to determine whether V_HC_κ would associate with the homologous 36-65-derived κ light chain to form an antigen-binding dimer; such a dimer would be analogous to a Fab fragment, except that it would have two C_L domains. It has been shown that V_H and V_L can associate to form a fully active antibody-combining site or Fv fragment[1,2]. Furthermore, X-ray crystallographic evidence suggests that in a light-chain dimer one monomer is oriented as the light chain while the other simulates the heavy chain in an antigen-binding Fab fragment[22]. It was therefore expected that a V_HC_κ–$V_\kappa C_\kappa$ dimer would function as a Fab fragment. For this experiment the source of 36-65κ chain was cell line 36-65L, a variant of the 36-65 cell line that synthesizes and secretes only the κ light chain and no heavy chain (isolated by J.S.). When V_HC_κ and the homologous 36-65κ light chain were associated *in vitro*, the resulting molecule bound to Ars-bovine γ-globulin (Ars-BGG)–Sepharose. SDS-polyacrylamide gel electrophoresis of the affinity-bound protein (Fig. 4*Ab*, MIX) and densitometric analysis showed that the V_HC_κ and the 36-65κ chain were present in a 1:1 molar ratio. Binding to Ars-BGG–Sepharose was significantly reduced by competition with Ars-tyrosine hapten (Fig. 4*Ac*, MIX). λ Chain, [illegible] amounts of ~30% of the κ or V_HC_κ chain, also bound to the Ars-BGG–Sepharose (Fig. 4*Ab*, MIX); this binding is evidently nonspecific because, unlike that of the κ and V_HC_κ chains, it is not competed for by the Ars-tyrosine hapten (Fig. 4*Ac*, MIX). L9E84 cells produce large amounts of this chain (see Figs 2*b*, 4*Aa*), and ~2% of the input chain binds to the Ars-BGG resin.

These data suggest that a V_HC_κ chimaera can associate with light chain *in vitro* to form an antigen-binding molecule. We estimate, from densitometer tracing of gel autoradiograms (not shown), that 20–30% of the V_HC_κ protein had associated with 36-65 light chain to form a functional binding site.

We have recently succeeded in introducing the V_HC_κ gene into 36-65L cells by fusion of 36-65L cells with myeloma cells that had been transfected with the V_HC_κ gene (J.S., unpub-

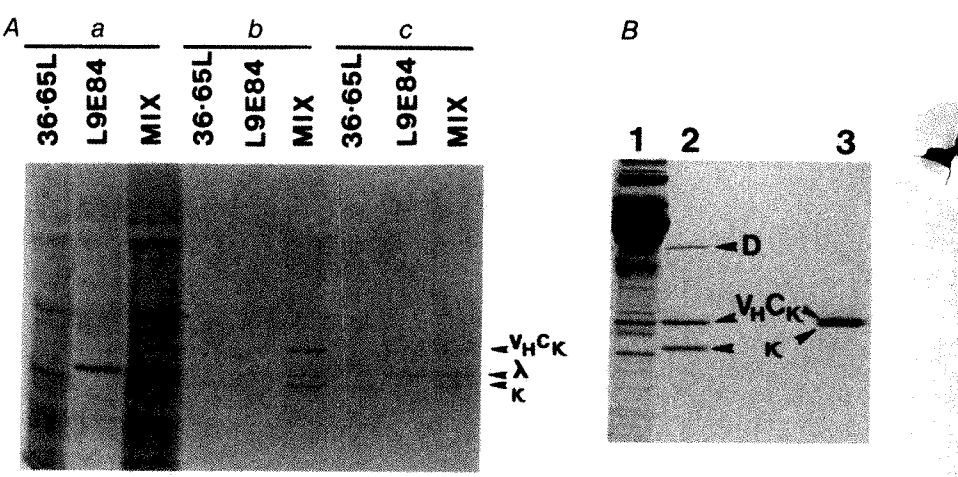

Fig. 4 Association of V_HC_κ with 36-65 κ light chain to form an antigen-binding molecule. *A*: *a*, Dialysed cell extracts and mix preabsorbed with BGG–Sepharose. One-fifth the amount used for binding to Ars-BGG–Sepharose was applied to the gel. *b*, Protein bound to Ars-BGG–Sepharose. *c*, Protein bound to Ars-BGG–Sepharose in the presence of 0.5×10^{-3} M Ars-tyrosine (ABA-tyrosine from Bioresearch, San Rafael, California). The positions of V_HC_κ, λ and 36-65 κ chain are indicated. *B*, SDS-polyacrylamide gel electrophoresis of V_HC_κ–$V_\kappa C_\kappa$ dimers purified from 25D3 ascites. Lane 1, 2 μl of ascites, in non-reducing conditions; lane 2, purified V_HC_κ–$V_\kappa C_\kappa$ dimers in non-reducing conditions; lane 3, purified V_HC_κ–$V_\kappa C_\kappa$ dimers, in reducing conditions. The positions of V_HC_κ, κ and covalent dimers (D) were determined from their ^{35}S-biosynthetically labelled counterparts in cell line 25D3, and are indicated by arrows.

Methods: *A*, L9E84 and 36-65L cells were biosynthetically labelled separately with ^{35}S-methionine and cell extracts prepared as described in Fig. 2 legend. Portions of 36-65L, L9E84 and an equal mixture of the two extracts (MIX) were made up to 0.5 M in propionic acid to dissociate interchain noncovalent interactions. After 30 min at room temperature the individual extracts and the mix were dialysed exhaustively against 5 mM of Na-acetate *p*H 5.5 at 4 °C to allow association into dimers[31,32], and finally against phosphate-buffered saline (PBS) at room temperature. The dialysed extracts and the mix were preabsorbed with BGG-coupled Sepharose for 2.5 h at 4 °C to reduce nonspecific binding, and then portions of each were mixed with 15 μl of Ars-BGG–Sepharose for 10 h at 4 °C in Eppendorf tubes. The resin aliquots were washed five times with 1 ml of PBS, 1 M NaCl, 0.5% NP40, once with 1 ml of ethylene glycol[33,34] in the above solution, and once with 1 ml of PBS. Bound protein was eluted with SDS sample buffer at 100 °C[35]. SDS-polyacrylamide gel electrophoresis in non-reducing conditions, and auto-radiography were as described[27]. Densitometer tracing and quantitation were done as described in Fig. 2 legend. (The ratio of methionine residues in V_HC_κ to those in 36-65 κ is 3:2.) *B*, Ascites was produced in (BALB/c × A/J) F_1 mice by intraperitoneal injection of 10^5 25D3 cells after priming with 0.5 ml of pristane (2,6,10,14-tetramethylpentadecane; Aldrich)[36]. Dimers with antigen-binding activity were purified by affinity chromatography on Ars-BGG–Sepharose. Elution was with 0.2 M NH_4OH. The eluted material was chromatographed on an Ultrogel AcA 44 column (LKB) that had been calibrated with molecular weight markers; the bulk of the material was recovered as a 55,000-molecular weight protein peak. SDS-polacrylamide gel electrophoresis was performed as described above, and proteins were visualized by Coomassie blue staining.

lished). This resulted in *in vivo* association of V_HC_κ with the light chain of 36-65. Formation of functional antibody molecules *in vivo* following transfection of heavy and light chains into myeloma cells has been demonstrated[23]. Ascites from (BALB/c×A/J)F_1 mice that had been injected with the hybrid cell line, 25D3, contains the V_HC_κ–$V_\kappa C_\kappa$ dimer. This dimer was purified by affinity chromatography on Ars-BGG–Sepharose. Gel filtration chromatography indicated a molecular weight of 55,000, as expected. SDS-polyacrylamide gel electrophoresis showed the presence of V_HC_κ, κ and covalent dimers (Fig. 4*B*).

Measurements of the fluorescence quenching of the V_HC_κ–$V_\kappa C_\kappa$ dimer and of 36-65 hybridoma protein by Ars-tyrosine were made as described[24] and used to calculate K_a. The K_a values for the association of V_HC_κ–$V_\kappa C_\kappa$ and that of the 36-65 protein with Ars-tyrosine (assuming one binding site per molecule for the V_HC_κ–$V_\kappa C_\kappa$ dimer and two binding sites per molecule for the 36-65 protein) are essentially the same: $3.8\times10^5\ M^{-1}$ and $4.2\times10^5\ M^{-1}$, respectively. A similar value was determined previously for hybridoma protein 36-65 (ref. 24).

It would be interesting to compare X-ray crystallographic studies of the V_HC_κ–$V_\kappa C_\kappa$ dimer and of the Fab fragment of 36-65 protein. The dimer might be a good candidate for crystallization because of its increased symmetry compared with Fab fragments. (It has been observed that some Fab fragments cannot be induced to crystallize[25].) Such structural studies might provide insights into designing antibody molecules consisting of V_H and V_L attached to other molecules of interest such as enzymes and toxins.

We thank the Eli Lilly Company for supplying mycophenolic acid; M. Pereira, P. Silver and R. Wharton for reading the manuscript; T. Rothstein for advice on the fluorescence quenching experiments; and B. Ransil for use of his computing facilities in the Department of Medicine, Beth Israel Hospital and Harvard Medical School. J.S. was supported by a postdoctoral fellowship from the Damon Runyon–Walter Winchell Cancer Fund, DRG-531, and recently by a postdoctoral fellowship from the NIH (AI06651). This work was supported in parts by NIH grant AI18589 to M.P., NIH grants CA28900 and AI13357 and American Cancer Society grant NP6M to M.L.G, American Cancer Society grant PF-2440 to T.M., and NIH grants CA16858 and CA22736 to S.L.M.

Schwann cells induce morphological transformation of sensory neurones *in vitro*

Anne W. Mudge

MRC Neuroimmunology Programme, Department of Zoology, University College London, Gower Street, London WC1E 6BT, UK

Cell–cell interactions are thought to play a crucial part in determining the developmental fate of vertebrate cells and regulating their subsequent differentiation. In the peripheral nervous system, for example, signals from neuronal axons determine whether or not some Schwann cells wrap their plasma membrane concentrically around the axon to form a myelin sheath[1,2]. Moreover, there is some evidence that the interactions between Schwann cells and neurones are not all one way: for example, Schwann cells are thought to provide signals for neuronal sprouting and regeneration[3–5]. However, there are no clear examples in which Schwann cells have been shown to influence the normal development of neurones. Here I have used purified populations of embryonic sensory neurones and Schwann cells to demonstrate that Schwann cells have a dramatic influence on the development of these neurones. In the presence of Schwann cells, but not other cell types, the sensory neurones undergo a morphological transformation from an immature bipolar form to a mature pseudo-unipolar form. This provides a striking example of the importance of glial cells for neuronal development.

During development in the dorsal root ganglion (DRG) of birds and mammals, sensory neurones are initially bipolar in form, extending one axon to the periphery and the other to the spinal cord. During the second half of development, these neurones undergo a remarkable change in morphology well described by Ramon y Cajal[6]. The cytoplasm of the neuronal cell soma bulges to one side and the two axons approach one another so that the cell becomes bell-shaped. Eventually the cytoplasm between the cell body and the processes elongates to form the initial segment of the axon from which the original processes emanate (see Fig. 1). This change from bipolar to pseudo-unipolar morphology is associated with a rearrangement of the cell body cytoplasm and cytoskeleton[7,8].

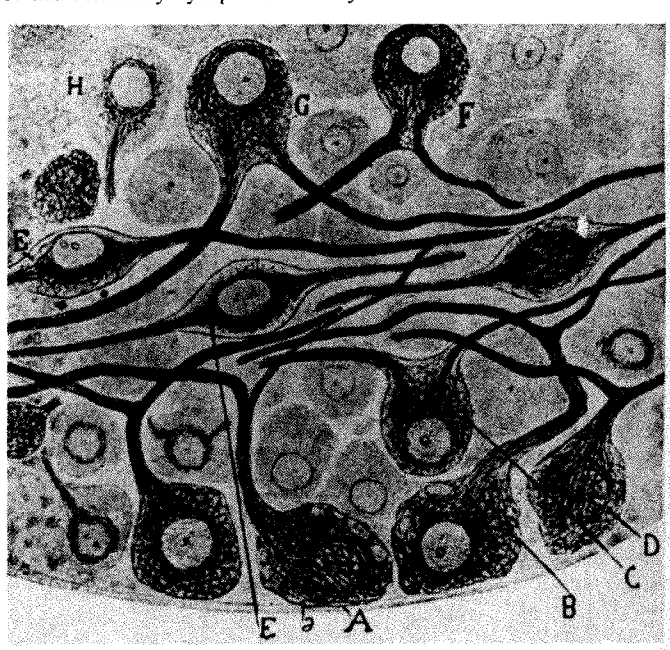

Fig. 1 DRG neurones from 14-day-old chick embryo, stained with silver nitrate. This drawing which shows the transition of bipolar sensory neurones to the pseudo-unipolar form is reproduced from ref. 6.

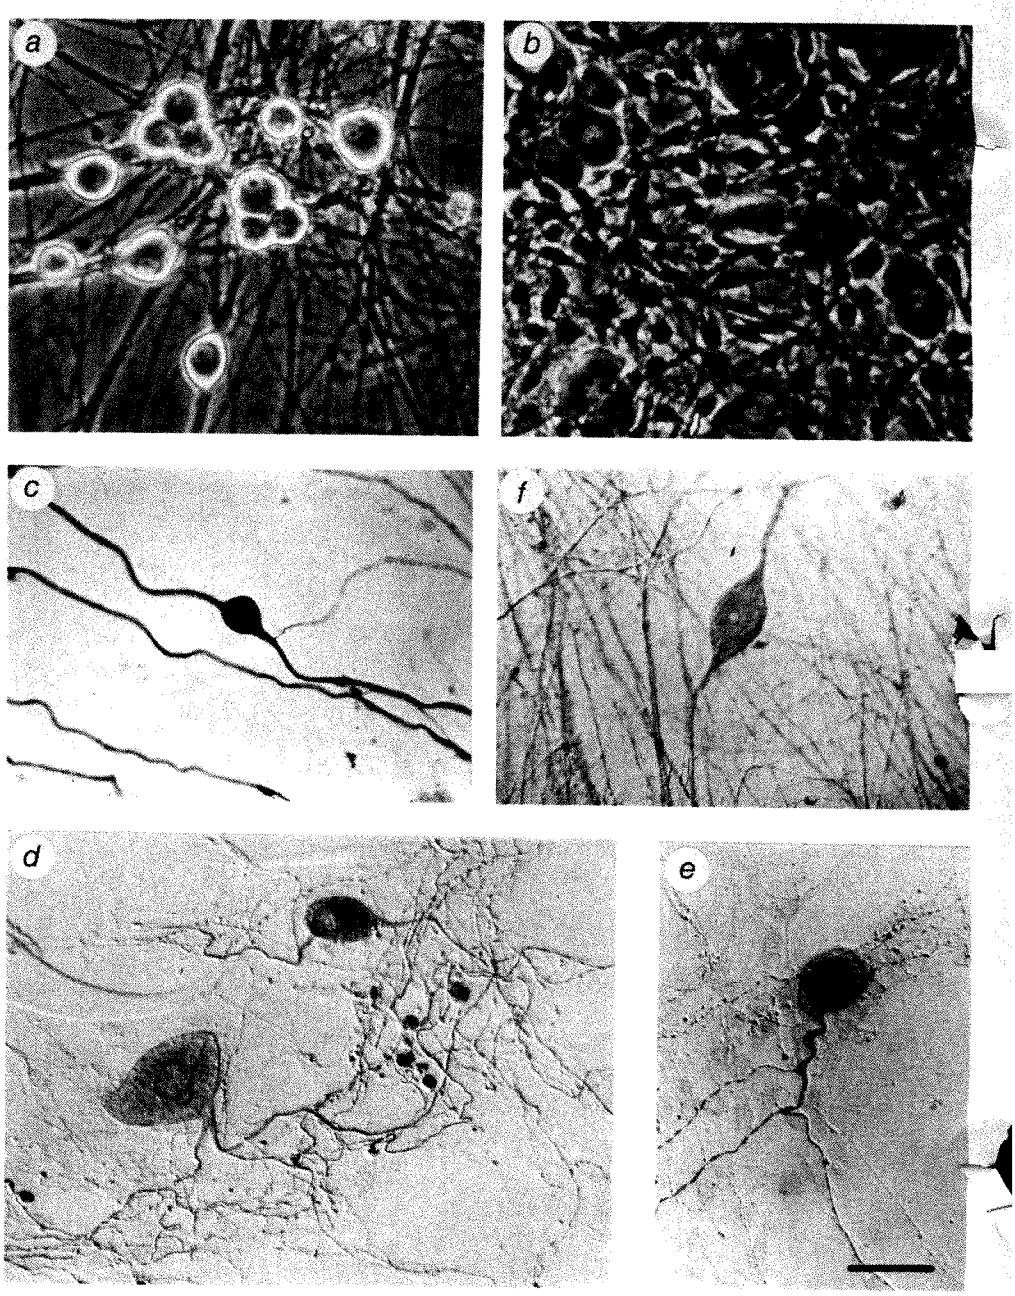

Fig. 2 *a*, *b*, Phase-contrast micrographs of sensory neurones grown for 10 days without the addition of Schwann cells (*a*), or grown for 5 days after the addition of Schwann cells (*b*). *c*, Sensory neurone grown for 15 days on a collagen substrate in the absence of non-neuronal cells. *d*, Sensory neurones 10 days after the addition of Schwann cells. The neurones appear to be undergoing a transition to the pseudo-unipolar form. *e*, Sensory neurone 10 days after the addition of Schwann cells. *f*, Sensory neurone grown on extracellular matrix material laid down by bovine endothelial cells. Scale, 50 μm.

Methods: ***a***, ***b***, DRGs from 9–10-day-old chick embryos were dissociated using 0.1% Dispase (Boehringer Mannheim) in Ca^{2+},Mg^{2+}-free saline and plated onto collagen-coated 35-mm tissue culture dishes (Falcon) or 16-mm glass coverslips in 24-multi-well trays (Linbro). Cells were grown in minimal essential medium containing 10% heat-inactivated horse serum, 5% chick embryo extract, 2 mM glutamine, 50 μg ml^{-1} penicillin, 50 U ml^{-1} streptomycin and 1 μg ml^{-1} nerve growth factor as previously described[9,10]. The cultures were treated with 5×10^{-6}M cytosine arabinoside for 5 days to eliminate non-neuronal cells. At this time, purified Schwann cells were added to some of the neurone-alone cultures. The plating density of the Schwann cells was either 200,000 per 35 mm dish or 50,000 per 19 mm multi-well with coverslip. ***c–f***, Sensory neurones plated at low density and labelled with anti-NF antibody viewed with Nomarski optics. Cultures were fixed with 4% paraformaldehyde followed by extraction with cold methanol. The extracted cells were then incubated with a monoclonal antibody (RT 97)[12] to neurofilament proteins, washed and then incubated with anti-mouse Ig conjugated to peroxidase (Tago). The bound antibody was then visualized by reacting with diaminobenzidine (0.05%) and H_2O_2 (0.01%).

In the present experiments, DRGs were dissected from 9–10-day chick embryos, dissociated to single cells and plated onto collagen-coated glass coverslips or plastic tissue-culture dishes. The cultures were treated for 5 days with cytosine arabinoside (5×10^{-6} M) to kill most of the ganglionic non-neuronal cells[9,10]. After this period purified Schwann cells were added to some of the neuronal cultures. The Schwann cells were obtained from newborn rat sciatic nerves and purified free of fibroblasts by pulsing with cytosine arabinoside (10^{-5} M for 2 days) followed by complement-mediated cell lysis of Thy 1.1-positive fibroblasts according to the method of Brockes *et al.*[11]. After growth for a further 5–15 days, the cultures were photographed, then fixed and labelled with a monoclonal antibody against neurofilament proteins (RT97; anti-NF)[12].

Most of the neurones in cultures of 9–10-day-old embryonic chick DRGs were phase bright and bipolar, and maintained this morphology for periods of up to 1 month if grown in the absence of non-neuronal cells (Fig. 2*a*, *c*). However, when purified Schwann cells were added, the morphology of the neurones changed dramatically within 5 days (see below). When viewed with phase-contrast optics, all the neurones had become flat and phase-dark; moreover, the initial segment of the axons appeared thicker (Fig. 2*b*). Labelling the mixed cultures with anti-NF antibody showed that all the neurones had changed from the bipolar to the pseudo-unipolar form. Figure 2*c–e* shows neurones grown at low density with and without the addition of Schwann cells and labelled with anti-NF. This set of cultures was chosen for illustration because they clearly show the intermediate forms reminiscent of Ramon y Cajal's drawings (Fig. 2*d*).

The time required for this change to occur was related to the number of Schwann cells added: with high densities of Schwann cells the change occurred in less than 1 week, the first 'flattening' being observed after 3 days. With low numbers of Schwann cells, the change occurred after a longer period (up to 15 days); however, when the neurones eventually flattened, the majority did so over a period of a few days. Although the dependence on Schwann cell number and the synchrony of the transition suggested that a secreted factor might be responsible for the effect, attempts to induce the morphological change with super-

natants from Schwann cell cultures were unsuccessful. This suggests that neuronal–Schwann cell contact may be required.

Of the cells tested, only Schwann cells were able to induce the morphological change in DRG neurones. Fibroblasts from either rat or chick skin, chick myotubes, rat cortical astrocytes, or the glial cell lines RN22 and C6, had no effect on neuronal morphology when added to DRG cultures. Changing the composition of the substrate by adding fibronectin and/or laminin to the collagen also had no effect. Similarly, DRG neurones cultured on the extracellular matrix material laid down by bovine endothelial cells[13] remained in the bipolar form after 2 weeks, although this matrix greatly stimulated neurite extension. (Fig. 2*f*). Therefore if extracellular matrix components are involved in the change, these components seem to be specific to the Schwann cells.

The present experiments used early embryonic chick neurones and purified rat sciatic nerve Schwann cells. Fortunately, the mechanism of this signalling between Schwann cells and neurones seems to be conserved between species. Chick rather than rat DRG neurones were studied because of the relative ease of culturing early embryonic chick neurones free of non-neuronal cells; many of the neurones taken from chick embryos older than 10 days (or rat embryos older than 15 days) have already been signalled to become pseudo-unipolar, and when put into culture retain this morphology. Rat Schwann cells were used because of the availability of methods for identifying and purifying these cells; comparable methods for identifying and purifying chick Schwann cells are not available. However, I have found that chick non-neuronal cells enriched for glial cells (using spindle-shape morphology as a criterion) also promote the morphological transformation of chick sensory neurones. Dichter and Fischbach[14] noted the presence of a few 'flat' phase-dark chick DRG neurones, which were probably pseudo-unipolar, in cultures grown in the presence of ganglionic non-neuronal cells that were mostly mesenchymal rather than glial cells. Other workers[15] have described the presence of pseudo-unipolar sensory neurones in unpurified rat DRG cultures containing both rat neurones and Schwann cells. However, because of the heterogeneity of the cell populations used, no specific interaction between two identified cell types could be identified in any of these three cases.

The present report illustrates the power of using purified cells to determine which of the properties of differentiated neurones are intrinsic to these cells and which depend on interaction with other cell types. There is a striking similarity between the transformation seen in these cell mixing experiments *in vitro* and that seen during the normal development of sensory neurones *in vivo*. This, together with the fact that the transformation occurs at a time that correlates with Schwann cell proliferation in the DRG[16], suggests that Schwann cells play a crucial part in mediating this morphological change *in vivo* as well as *in vitro*.

I thank Rasila Patel for technical help, Richard Hynes for help in preparing fibronectin, G. Martin for the gift of laminin, C. Kintner for the matrix-coated coverslips, and Martin Raff and my colleagues in the Neuroimmunology Project for their helpful comments.

Epstein–Barr virus transforms precursor B cells even before immunoglobulin gene rearrangements

Shigeru Katamine*, Masayuki Otsu, Kotaro Tada, Shigeru Tsuchiya, Tetsuo Sato, Nakao Ishida, Tasuku Honjo† & Yasushi Ono

Department of Bacteriology, Tohoku University School of Medicine, 2-1 Seiryo-machi, Sendai 980, Japan
† Department of Genetics, Osaka University School of Medicine, Osaka 530, Japan

The very early stages of the human B-cell differentiation pathway are poorly understood, primarily because of the lack of appropriate permanent cell lines. Epstein–Barr virus (EBV) is a putative human oncogenic virus which transforms human B cells *in vitro* into continuously proliferating cells[1]. It has been believed that EBV transforms mature B cells[2,3] but recently, transformation of immature pre-B-cell lines has been reported[4–6], suggesting that EBV might also transform cells much earlier in the B-cell lineage. We report here the establishment of cell lines transformed by EBV at various stages of the B-cell differentiation pathway. Interestingly, two lines showed the complete absence of immunoglobulin synthesis and the lack of immunoglobulin gene rearrangement despite containing EBV genome and surface markers of B cells. Our results indicate that EBV can infect and tranform cells of the B lymphocyte lineage even before immunoglobulin gene rearrangement.

EBV was obtained from the culture fluid of the B95-8 marmoset cell line[7]. The fetal liver was obtained from an embryo artificially aborted at the 16th week of gestation. Mononuclear cells separated by Ficoll–Conray gradient centrifugation were infected with EBV at a multiplicity of infectivity of 0.1. Infected cells were distributed into microculture plates (no. 3042, Falcon) at a density of 1×10^5 cells per well in RPMI 1640 medium supplemented with 20% heat-inactivated fetal bovine serum, 0.2 mM L-serine, 1 mM pyruvic acid, 2 mM L-glutamine, 100 U ml^{-1} of penicillin, 100 $\mu g\ ml^{-1}$ of streptomycin and 10 mM HEPES and were cultured at 37 °C in an atmosphere of 5% CO_2 in air[8]. After 30–40 days, transformation occurred in 30% of the wells, as determined by the morphological appearance of lymphoblastoid cells, increase of cell numbers and acid production.

The immunoglobulin phenotypes of 24 cell lines thus obtained were examined (Table 1). The various cell lines showed different immunoglobulin production and were classified into four groups. Of the 24 cell lines, 20 were IgM producers which had both cytoplasmic and surface μ and light chains. The amounts of IgM secreted in culture fluid varied over 270–52,500 ng ml^{-1}. The light chains made by all of these cell lines except FLEB5 were κ isotype. This finding may reflect the dominant expression of κ isotype in the fetal liver B cells, and supports the hypothesis that the κ-chain gene is activated before the λ-chain gene in human B-cell ontogeny[9]. Another cell line, FLEB12, synthesized only μ chains in the absence of light chains and therefore appeared to represent a pre-B cell[10,11]. Using the method of double colour staining[12], 60% of the FLEB12 cells possessed μ chains only in the cytoplasm but 10% had μ chains both in the cytoplasm and on the cell surface (data not shown). This result supports the proposal that μ and light chains may not need to be assembled for expression on the cell surface. In the case of line FLEB20, only κ chains were detected. This might be a similar cell line to those mouse cell lines reported by Siden *et al.*[13] which produce light chains only but have rearranged heavy-chain genes[14]. Unfortunately, the FLEB20 was subsequently lost. The remaining two cell lines, FLEB14 and 18, showed complete absence of immunoglobulin synthesis.

The amounts of IgG and IgM were determined by an inhibition radioimmunoassay described by Platts-Mills and Ishizaka[24]. Briefly, immunoadsorbent column-purified IgG and IgM were labelled with ^{125}I(NEN) by the chloramine-T method. 100 µl of appropriately diluted supernatants and standard human IgG (or IgM) were mixed with 0.1 ml of rabbit anti-human IgG (or anti-human IgM) serum. After 2 h incubation at room temperature, 0.1 ml of ^{125}I-labelled IgG (or IgM) (59 ng ml^{-1}) was added and incubated for another 2 h at room temperature. Then 0.1 ml of goat anti-rabbit IgG serum was added and allowed to stand overnight at 4 °C. The precipitates were spun down and radioactivity was counted using an autogamma-counter. Cytoplasmic and surface immunoglobulins were detected by direct immunofluoresence. The cells were smeared on a coverslip, fixed in acetone at −20 °C and stained for cytoplasmic immunoglobulin with fluorescein isothiocyanate (FITC)-coupled rabbit monospecific antisera, F(ab')$_2$ fragment, against human μ, δ, γ, α, κ and λ chains. Surface immunoglobulin was stained by the method of Kumagai *et al.* after treatment with acid *p*H[25].

Three representative cell lines (FLEB2, 12 and 14) were subcloned in semi-solid agarose. Each subclone conserved the same characteristics as the parental cell lines. To confirm the immunoglobulin phenotypes of three subcloned lines (FLEB2, 12 and 14), the cells were metabolically labelled with ^{14}C-leucine and their cell lysates and culture fluids were immunoprecipitated with purified anti-μ serum. The precipitated polypeptides were analysed by SDS–polyacrylamide gel electrophoresis (PAGE) (Fig. 1). In the lysate (lane 1) and culture fluid (lane 4) of FLEB2 the molecular weights (MWs) of two observed polypeptides were 76,000 and 29,000, corresponding to those of authentic μ and light chains purified from human serum. In the case of FLEB12 (Fig. 1, lanes 2, 5), two μ-related polypeptides were detected in the lysate but no precipitable polypeptides were observed in the culture fluid. The minor band of the lysate was 76,000 MW and identical in size to the standard μ chain, while the major one was ~80,000 MW. This higher molecular weight may result from differences in the length of these polypeptides and/or in the degree of glycosylation. Alternatively, it may not be a μ-gene product, such as the supposed heavy-chain binding protein (BiP) noncovalently bound to heavy chains reported in murine pre-B-cell lines[15]. The anti-μ antibody did not precipitate any molecules at all in the case of FLEB14 (lanes 3 and 6). Thus, FLEB14 was completely lacking in immunoglobulin expression.

To determine whether FLEB14 belonged to the B-cell lineage or not, the lines were tested for various other markers (Table 2). Like the other cell lines tested, FLEB14 possessed Fc μ receptors, C3 receptors and HLA-DR antigens, which are characteristic of B cells, although not unique to them. They lacked any T-cell markers and peroxidase activities. In addition, FLEB14 was positive for EBV-induced nuclear antigens

EBNA was detected according to the method of Reedman and Klein[16]. Rosette formation of the cells was performed by the method of Tachibana *et al.*[26]. Neuraminidase-treated sheep erythrocytes (SRBC) were used for E-rosette formation. Cells with IgG-Fc or IgM-Fc receptors were tested with IgG- or IgM-coated ox erythrocytes. IgM–human complement-coated SRBC and IgM-C5-deficient mouse complement-coated SRBC were used for detection of C3b and C3d receptors. HLA-DR antigen, CALLA(J5)[27] and T-cell differentiation antigens (Leu 1, Leu 2a, Leu 3a, Leu 4) were tested by fluorocytometry using murine monoclonal antibodies (Becton Dickinson). Terminal deoxynucleotidyl transferase (TdT) activity was determined according to the method of Tofen *et al.*[28]. Peroxidase staining was performed by a standard method.

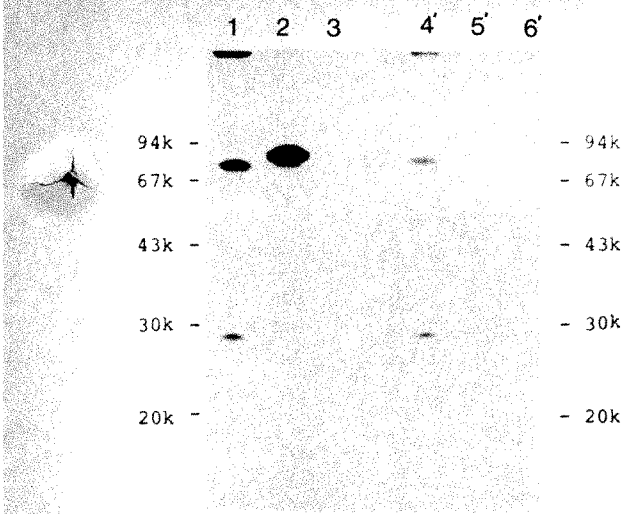

Fig. 1 Lanes 1, 2 and 3 are from cell lysates of FLEB2, 12 and 14. Lanes 4, 5 and 6 are from culture supernatants of FLEB2, 12 and 14. Cells were cultured at 5×10^6 cells per ml with 5 μCi ml^{-1} of ^{14}C-leucine (NEN) for 2–12 h in leucine-free minimal essential medium supplemented with 10% heat-inactivated fetal calf serum. After labelling, the culture media were saved. The cells were washed wice with cold phosphate-buffered saline and were lysed in lysis uffer containing 10 mM sodium phosphate *p*H 7.4, 0.1 M NaCl, 1% Triton X-100, 0.5% sodium deoxycholate, 0.1% SDS, 1 mg ml^{-1} of bovine serum albumin and 1 mM phenylmethylsulphonyl fluoride. The lysed cells were centrifuged at 100,000*g* for 60 min at 4° C and the supernatants were saved. The spent media and cell lysates were mixed with 10 μl of rabbit anti-human IgM serum. After 12 h incubation at 4° C, 0.1 ml of a 10% suspension of fixed *Staphylococcus aureus* Cowan I was added and incubated for 2 h at room temperature followed by three washings. Bound immunoglobulins were removed and reduced in buffer containing 10 mM Tris-HCl *p*H 6.8, 6.2 M urea, 2.3% SDS and 5% 2-mercaptoethanol for 3 h at 70° C, and *S. aureus* was removed by centrifugation. Reduced samples were separated on a 10–15% gradient polyacrylamide gel according to the method of Laemmli[29]. Following electrophoresis, the gel was fixed and fluorographed.

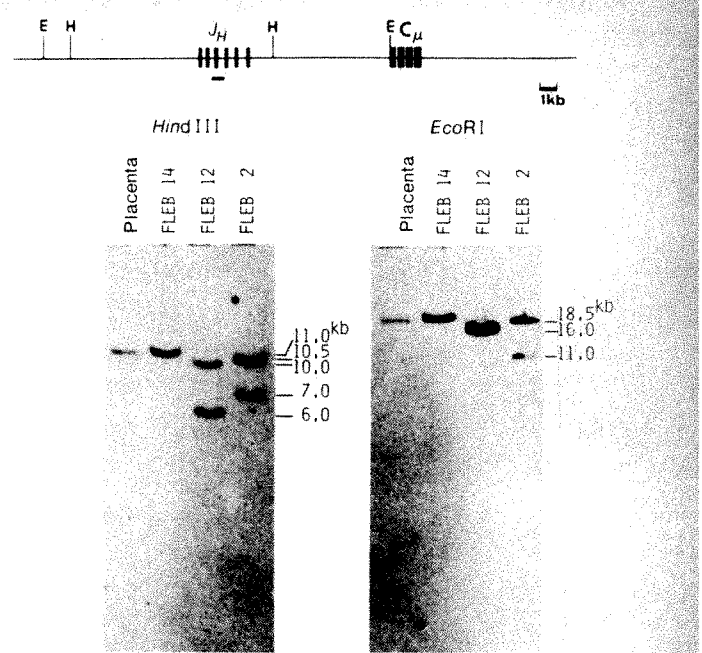

Fig. 2 Immunoglobulin heavy-chain gene analysis of FLEB2, 12 and 14 cell lines with a cloned human J_H gene fragment as a probe. High molecular weight DNA was isolated from each cell line according to the method of S. Gattoni (personal communication)[30]. The human placental DNA was used as a control. The fragments obtained by *Hin*dIII or *Eco*RI digestion of DNA (about 2 μg) were size-fractionated by electrophoresis in a 0.5% agarose gel, transferred to a nitrocellulose filter according to the method of Southern[31], then hybridized with a ^{32}P-labelled cloned J_H gene probe (specific activity 3×10^8 d.p.m. per μg). The probe used was a 0.7-kb *Hha*I–*Hha*I fragment of Ch4A.H.Igμ-24 (ref. 22) which is indicated by a bold bar below the restriction map. The labelling of the probe was performed by nick-translation as previously described[32]. In the restriction map, structural genes are indicated by closed rectangles, and restriction sites of *Hin*dIII and *Eco*RI are shown by H and E, respectively.

(EBNA)[16], thus they must have receptors for EBV[17]. It has been suggested that the presence of EBV receptor could be considered as a B-cell marker[17,18]. The common acute lymphoblastic leukaemia antigen (CALLA), which is limited to expression mainly on pre-B cells[19], was not detected on FLEB14 cells. Therefore, FLEB14 appears to be committed to the B-cell lineage but definitive assignment can be made only if immunoglobulin production can be induced.

As the first event characteristic of B-cell ontogeny is the rearrangement of immunoglobulin genes, it was of interest to know the immunoglobulin gene organization of FLEB14. It has been demonstrated that heavy-chain gene rearrangement precedes that of light-chain genes, and is accomplished by the joining of V_H, D and J_H gene segments[20,21]. The DNA fragments containing J_H before rearrangement, digested by *Hin*dIII or *Eco*RI, are 11.0 or 18.5 kilobases (kb)[22] in length, respectively. The DNAs from cells of three of these lines (FLEB2, 12 and 14) and human placental cells as germ-line control were digested with *Hin*dIII or *Eco*RI (Fig. 2). *Hin*dIII digests of FLEB2 gave J_H positive fragments of 10.5 and 7.0 kb and from FLEB12, fragments of 10.0 and 6.0 kb. None of these corresponded to the fragment of the human placental DNA (11.0 kb). FLEB14, however, showed the fragment of the germ-line size. Similarly in *Eco*RI digestion, J_H-positive fragments of 18.5 and 11.0 kb in FLEB2 and 16.0 kb in FLEB12 were detected, indicating that the immunoglobulin genes had undergone rearrangement in these cell lines. *Eco*RI-digested DNA of FLEB14, however, again produced only one band of 18.5 kb, identical in size to that found in the human placental DNA. These results show that somatic rearrangement of the heavy-chain gene has already occurred in FLEB2 and 12, but that in FLEB14 the heavy-chain gene retains its germ-line configuration. Based on other experiments, the light-chain genes also conserve the embryonic configuration in FLEB14 (M.O., unpublished results).

These cell lines should therefore provide a useful model for studying the regulation of B-cell differentiation. Of particular interest is one cell line, FLEB14, which makes neither heavy nor light chain and has no immunoglobulin gene rearrangement despite carrying B-cell markers. This line may be the first example of the category of 'ur-B cell', proposed recently by Wabl *et al.*[23]. If immunoglobulin gene rearrangement in FLEB14 can be successfully induced, it will provide a system in which to study the earliest molecular aspects of immunoglobulin gene activation. In preliminary experiments, we have obtained some evidence suggesting heavy-chain gene reorganization in FLEB14 during successive cultivation (M.O., to be published).

We thank Dr S. Hino and Mrs S. Watanabe for preparation of this manuscript. This research was partially supported by a grant from the Ministry of Education, Science and Culture of Japan. M.O is supported by a doctoral fellowship from JSPS.

Relaxin affects the central control of oxytocin release

A. J. S. Summerlee, K. T. O'Byrne, A. C. Paisley, M. F. Breeze & D. G. Porter

Department of Anatomy, The Veterinary School, University of Bristol, Bristol BS8 1TD, UK

In several species the myometrium is quiescent shortly before parturition[1]. At this time high titres of relaxin are present in the plasma[2] and there is evidence[3] that the hormone has a direct inhibitory action on the uterine muscle. Relaxin could also contribute to uterine quiescence by inhibiting oxytocin release. To determine whether relaxin has a central action on the release of oxytocin, we have studied the effect of intravenous injections of porcine relaxin on milk ejection in the anaesthetized lactating rat. We report that reflex milk ejection was suppressed by relaxin in a dose-dependent manner, the onset of inhibition being rapid and lasting from 10 to 60 min. After the period of inhibition the normal temporal pattern of reflex milk ejection was resumed. Mammary sensitivity to exogenous or endogenous oxytocin was reduced by relaxin but not sufficiently to explain the effects observed. Furthermore, relaxin (1 μg per rat) injected into the cerebral ventricles profoundly disturbed the pattern of reflex milk ejection without affecting the response of the mammary gland to oxytocin. These results suggest a novel role for relaxin within the central nervous system. The site in the brain at which the effects of relaxin are exerted remains unknown.

Rats were taken from the departmental colony where they had been housed in an environment of controlled light and temperature, with water and food available *ad libitum*. The day of delivery was denoted as day 1, and the animals were used between days 8 and 12 of lactation. The protocol for these experiments has been described in detail elsewhere[4]. Briefly, the young rats were separated overnight from their mother to promote mammary engorgement. The following morning the lactating rats were anaesthetized with ethyl carbamate (1.25 g per kg intraperitoneal, i.p.; urethane, BDH) and 2.5 mg intramuscular (i.m.) xylazine (Rompun; Bayer). A saphenous vein and two caudal mammary glands were cannulated and the animal was left for 3 h to stabilize after surgery. Ten hungry young rats were then allowed to suck at the nipples—this stimulus caused the onset of reflex milk ejection characterized by an abrupt and transient rise in intramammary pressure[5], together with the behavioural response of the sucking young. The latency to the first milk ejection was 12 min (mode) with a range of 5–48 min and thereafter occurred every 3–7 min. After at least eight milk ejections had been observed as a control, purified porcine relaxin, prepared by the method of Walsh and Niall[6], was given in 0.2 ml isotonic saline by intravenous (i.v.) injection. Three doses of relaxin were tested (2.5, 5 and 10 μg). Milk ejection was considered to be inhibited if intervals between successive milk ejections were significantly longer than intervals in the pretreatment period (see Fig. 1 for statistical analysis).

Injection of relaxin at all three doses cause a clear suppression of reflex milk ejection (Fig. 2); this effect was dose-dependent

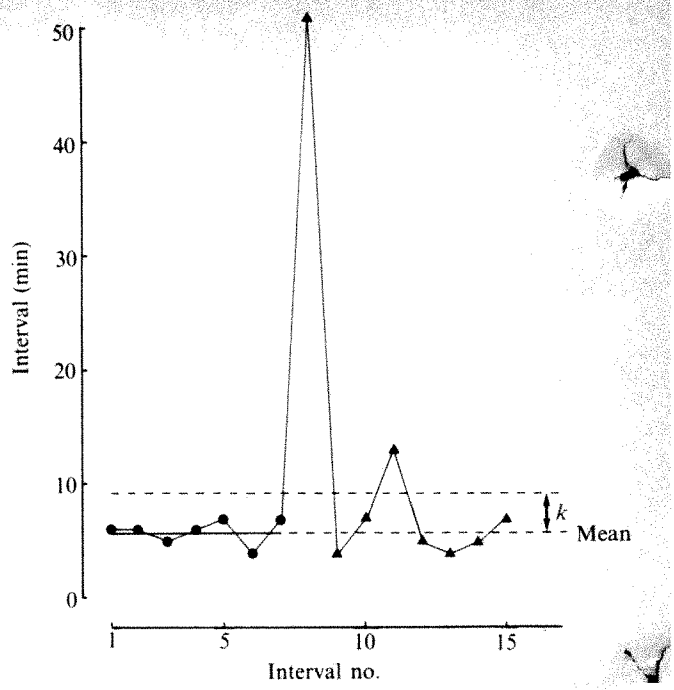

Fig. 1 Analysis used to assess the inhibition of reflex milk ejection by relaxin. This approach was first described by Clarke *et al.*[4]. Intervals between successive milk ejections are plotted sequentially, before (●) and after (▲) injection of relaxin. The lower horizontal line is the mean interval between milk ejections before treatment. The upper dashed line represents a 99% probability estimate ($P = 0.01$) based on the equation $k = \text{s.d.} \times t\sqrt{[(n+1)/n]}$* where s.d. = standard deviation of the milk ejection interval before treatment, n = number of control intervals; t = 't'-value for $n-1$ degrees of freedom at $P = 0.01$ and * = Bessel's correction for small size of preinjection sample. Milk ejection was judged to have been significantly inhibited if any milk ejection interval, within 30 min of relaxin treatment, exceeded the calculated level above.

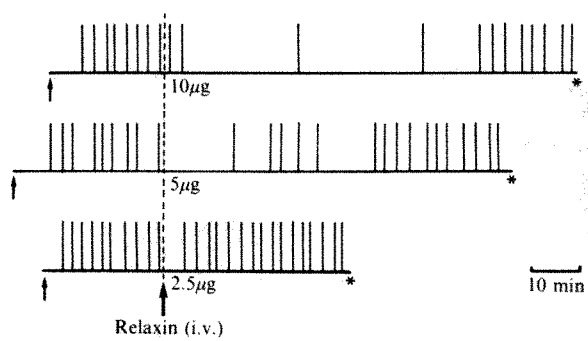

Fig. 2 The effects of intravenous injection of porcine relaxin on the pattern of reflex milk ejection in three suckled, urethane-anaesthetized rats. Each vertical bar corresponds to an intramammary pressure cycle characteristic of milk ejection (↑, onset of sucking stimulus of 10 young rats; *, termination of experiment). The three traces have been aligned with respect to the time of administration of relaxin. Reflex milk ejection was suppressed in a dose-dependent manner (see Table 1).

(Table 1) and lasted from 10 to over 60 min from the time of injection. During periods of inhibition the sensitivity of the mammary gland to oxytocin was tested by i.v. injections of 0.5 mU oxytocin. On all occasions the gland responded to the oxytocin but sometimes after application of 5 or 10 μg relaxin, the amplitude of the pressure response was reduced by up to 50% (Fig. 3), although it was never abolished. After the period of inhibition, reflex milk ejections recommenced with a frequency similar to pretreatment rates. A second dose of relaxin (5 μg) was administered at least 2 h after the initial treatment in four animals; inhibition of the reflex still occurred but to a lesser degree. This might reflect a tachyphylactic response similar to that reported for the myometrium *in vitro*[7].

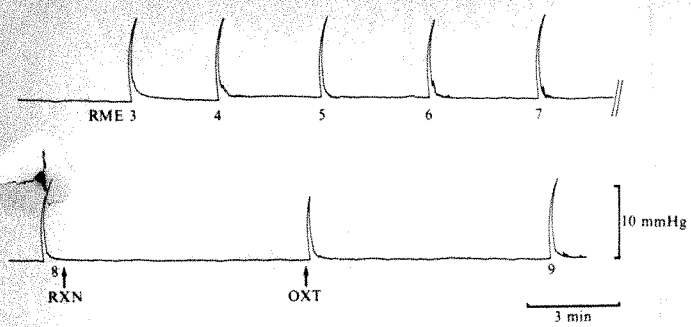

Fig. 3 The effect of relaxin on reflex milk ejection (RME) in an anaesthetized rat. The two traces of intramammary pressure responses are continuous. After the eighth RME, 10 μg relaxin (↑RXN) was injected i.v. Reflex milk ejection was suppressed for 16 min but during this time the mammary gland was still responsive to 0.5 mU exogenous oxytocin (↑OXT), suggesting that treatment with relaxin affected the central release of oxytocin.

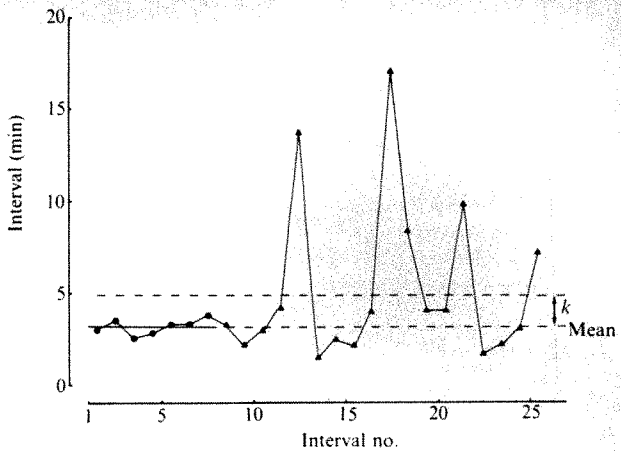

Fig. 4 The effect of intracerebroventricular relaxin on reflex milk ejection. Intervals between successive milk ejections are plotted sequentially before (●) and after (▲) injection of 1 μg relaxin. The lower dashed line is the mean interval between milk ejections before treatment and the upper dashed line represents 99% probability estimation of significant inhibition of the reflex. Reflex milk ejection was clearly suppressed after central administration of relaxin.

We tested the effect on reflex milk ejection of relaxin injected directly into the ventricular system of the brain in six animals. Rats which had been anaesthetized and prepared as described above were placed in a stereotaxic frame and a microsyringe (Hamilton 701N) positioned with its tip in one of the lateral cerebral ventricles. The tip was confirmed to be in the ventricular system by dye injection at the end of the experiment. Reflex milk ejection was initiated by the sucking young and after eight milk ejections, 1 μg relaxin in 1 μl isotonic saline was injected into the ventricle. Relaxin caused a profound disruption in the pattern of milk ejection (Fig. 4) but did not affect the response of the mammary gland to exogenous oxytocin in all six rats. Control injections of 1 μl isotonic saline ($n = 6$) did not affect the temporal pattern of reflex milk ejection. These data imply that the major component of the inhibitory effect of relaxin on milk ejected is exerted within the brain.

Control injections of 0.2 ml isotonic saline (two rats) and an extract of pig ovary (5 μg) shown to possess no relaxin immunoreactivity or bioactivity (uterine strip assay) did not alter the interval between reflex milk ejections in two and three rats respectively. Evidence suggests that electroencephalogram (EEG) synchrony may be a prerequisite for reflex milk ejection in the rat[8,9]. Therefore, we recorded the EEG activity in two anaesthetized lactating rats before and after the i.v. administration of relaxin (5 μg); in neither animal did relaxin alter the EEG activity, suggesting that the hormone did not change the animal's level of arousal. It is also unlikely that the effect of relaxin could be attributed to an action on blood pressure because previous experiments[10] demonstrated that relaxin in doses of up to 20 μg had no effect on arterial pressure.

A possible explanation of the results is that sensitivity of the mammary glands to oxytocin was diminished by relaxin. Therefore, we examined the effect of exogenous oxytocin on intramammary pressure in lactating rats before and after treatment with relaxin. Each injection of hormone (0.5–1 mU) produced an intramammary pressure cycle with a sharp rise and slow decline. These responses mimic the natural pressure changes seen at reflex milk ejection[5], and are relatively constant for a particular dose of hormone[5]. At lower doses the responses are variable; for this reason we used a standard dose of 0.5 mU of synthetic oxytocin (Syntocinon; Sandoz). Rats were anaesthetized and cannulated as described above. After 3 h, 0.5 mU oxytocin was injected i.v. and thereafter at 3-min intervals. A stable baseline of at least seven consistent responses was obtained as control in each animal before relaxin was given; the results are shown in Table 2. Only at doses of relaxin of 5 μg and 10 μg was partial inhibition recorded (Table 2) yet 2.5 μg relaxin caused a suppression of reflex milk ejection in 7 out of 10 rats (Table 1), and in all of six rats 1 μg of the hormone was effective when administered intracerebrally. Furthermore,

Table 1 Effects of porcine relaxin (i.v.) on reflex milk ejection in anaesthetized lactating rats

	Latency (min) to 1st RME [Mode (range)]	RME interval (min) (mean ± s.e.m.) Before relaxin	After relaxin	No. of rats inhibited	Duration (min) of inhibition [Mode (range)]	Milk ejection ratio (mean ± s.e.m.)
2.5 μg Relaxin ($n = 10$)	12 (5–34)	4.5 ± 0.4	5.2 ± 0.3	7/10	10 (4–16)	3.5 ± 0.7
5 μg Relaxin ($n = 10$)	10 (7–48)	4.7 ± 0.8	6.8 ± 0.7	10/10	14 (6–28)	5.9 ± 1.6
10 μg Relaxin ($n = 8$)	12 (6–31)	4.7 ± 0.6	9.9 ± 0.7	8/8	27 (23–>60)	11.0 ± 2.3

The statistical analysis used to assess inhibition is illustrated in Fig. 1. RME, reflex milk ejection. The milk ejection ratio is the duration of the longest interval which occurred within 30 min of relaxin treatment divided by the mean interval before treatment.

Table 2 Effects of porcine relaxin (i.v.) on oxytocin-evoked milk ejection

	No. of rats affected	% Reduction in amplitude of IMP [Mean (range)]	Latency (min) to onset [Mode (range)]	Duration of effect (min) [Mode (range)]
2.5 μg Relaxin ($n = 10$)	0/10	—	—	—
5 μg Relaxin ($n = 10$)	2/10	6.2 (4–90)	3 (3–6)	6 (6–12)
10 μg Relaxin ($n = 12$)	6/12	18.6 (4–92)	3 (3–12)	9 (6–18)

A steady baseline of at least seven consistent responses to 0.5 mU oxytocin given at 3-min intervals was obtained as a control before i.v. injection of relaxin. The reduction in amplitude of the intramammary pressure (IMP) response to exogenous oxytocin after relaxin treatment is expressed as a percentage of the control amplitude.

relaxin at doses of 5 μg and 10 μg only affected the mammary response to exogenous oxytocin for a maximum of 18 min (Table 2), considerably shorter than the period during which reflex milk ejection was suppressed (Table 1). These results indicate that although relaxin also has an effect on the myoepithelium, the block of reflex milk ejection by all three doses of relaxin cannot be explained solely by the peripheral action of the hormone.

Our findings suggest that the inhibitory effect of relaxin on milk yield as reported by Knox and Griffith[11] in rats, and Cowie *et al.*[12] in goats, had a central component. The results also suggest that relaxin reduces *pre partum* myometrial activity by a double mechanism, that is, by a direct effect on the smooth muscle of the uterus and by a central action to prevent oxytocin release.

We thank Miss Allison Hockey for technical assistance and Mr W. Phillips and his staff for providing the experimental animals. The work was supported by grants from the ARC and the MRC.

Identity of the proliferating cell nuclear antigen and cyclin

Michael B. Mathews, Robert M. Bernstein*, B. Robert Franza Jr & James I. Garrels

Cold Spring Harbor Laboratory, PO Box 100, Cold Spring Harbor, New York 11724, USA

Studies of growth regulation and cellular transformation will be assisted by the identification of proteins that are preferentially synthesized in dividing cells. The 'proliferating cell nuclear antigen' (PCNA), distinguished by its apparent association with cell division, is defined by reaction with an antibody found in the autoimmune disease systemic lupus erythematosus (SLE)[1,2]. This antibody reacts with proliferating cells including tumour cells but gives weak or undetectable immunofluorescence with resting cells of normal tissues[2–6]. Peripheral blood lymphocytes are devoid of PCNA until activated by mitogen *in vitro*. In synchronized cultures its level and distribution fluctuate through the cell cycle, with a striking accumulation in the nucleolus late in the G_1 phase and early in the S phase[3]. Many of these properties are shared by 'cyclin'. This nuclear protein, identified by its position in a two-dimensional separation of cell proteins, is also transformation-sensitive and is preferentially synthesized in the S phase[7–9]. We establish here that PCNA and cyclin are identical, and show that PCNA is an acidic nuclear protein of apparent molecular weight 35,000.

In a recent survey[10], we found anti-PCNA antibodies in about 3% of SLE sera. Immunoglobulins prepared from nine sera of this specificity all precipitated a protein of molecular weight 35,000 from ^{35}S-methionine-labelled HeLa cell extracts (Fig. 1*a*), and we conclude that this protein is the antigen. No evidence was found for an associated RNA species, in contrast to the ribonucleoprotein antigens recognized by certain other antibodies in SLE, but weak labelling of PCNA with ^{32}P-phosphate suggested that it is at least partly phosphorylated (R.M.B.,

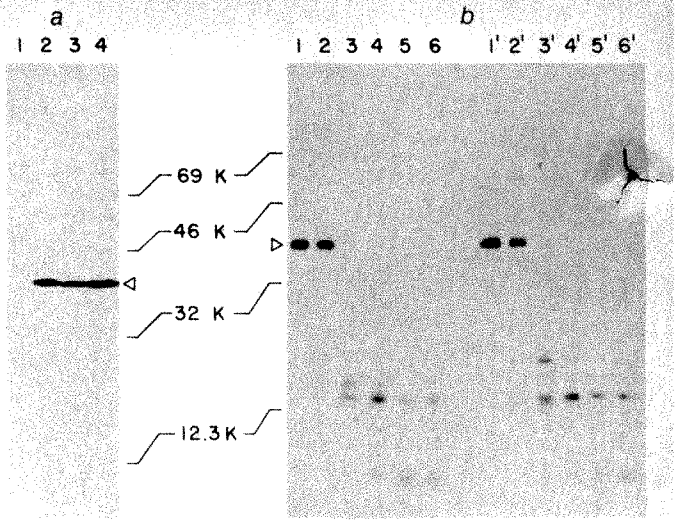

Fig. 1 Immunoprecipitation and peptide analysis of PCNA. *a*, Exponentially growing HeLa cell monolayers were labelled with ^{35}S-methionine for 5 h. Extracts were treated with control human IgG (lane 1) or with anti-PCNA IgG from each of three patients (lanes 2–4). Immune complexes were isolated using *S. aureus* as precipitant and were examined by electrophoresis in a 15% SDS-polyacrylamide gel as described elsewhere (ref. 16 and R.M.B., C. C. Bunn, G. R. V. Hughes, A. M. Francoeur and M.B.M., in preparation). *b*, Protein was extracted from gel bands containing immunoprecipitated PCNA (such as those in *a*) or from the two-dimensional gel spot identified as cyclin (as in Fig. 2*b*), by boiling in a solution containing 0.5% SDS, 10 mM 2-mercaptoethanol and 10 mM Tris-HCl *p*H 7.4. Aliquots of equal radioactivity were digested with protease from *S. aureus* strain V8 and examined in a 20% SDS-polyacrylamide gel. Lanes 1–6, immunoprecipitated PCNA incubated for 15 min at 37 °C with 0, 0.1, 1, 10, 100 and 1,000 ng of V8 protease. Lanes 1′–6′: two-dimensional gel-purified PCNA/cyclin (major spot) treated in the same way. Arrowheads indicate the PCNA band, and the positions of molecular weight markers are shown.

C. C. Bunn, G. R. V. Hughes, A. M. Francoeur and M.B.M., in preparation).

Examination of immunoprecipitates containing PCNA by two-dimensional gel electrophoresis (Fig. 2*a*) revealed a major spot with an apparent isoelectric point of 4.9 and MW ~35,000, together with a more acidic minor satellite spot. Removal of PCNA from the HeLa cell extract using anti-PCNA antibody led to the disappearance of both spots from the two-dimensional gel pattern (compare Fig. 2*b* and *c*), indicating that the spots contain PCNA only. Comparison of the HeLa cell protein pattern (Fig. 2*b*) with published gel patterns showed that PCNA resembles, in its apparent molecular weight and isoelectric point, the spot numbered IEF 49 and named 'cyclin' by Bravo and co-workers[7,8]. The identity of cyclin with PCNA was confirmed by an exchange of samples between our laboratory and that of J. Celis (data not shown), and by construction of one-dimensional peptide maps[10]. The peptides released from immunoprecipitated PCNA by partial proteolysis with *Staphylococcus aureus* V8 protease (Fig. 1*b*) closely resembled those from the two-dimensional gel spot (Fig. 1*b*′) and were similar in size and distribution to those published for cyclin[8,9]. A proteolysis pattern indistinguishable from that shown in Fig. 1*b*′ was also obtained from the acidic satellite spot eluted from a two-dimensional gel (not shown).

PCNA is a prominent component of many tumour cell lines, including HeLa. To examine the biological properties of the protein, we used the REF52 line of rat embryo cells and its virus-transformed derivatives[11]. Cultures of normal REF52 cells have a doubling time of 24 h and reach quiescence at a relatively low cell density, while Simian virus 40 (SV40)-transformed REF52 cells double in 18–19 h and reach a six- to eight-fold higher saturation density. PCNA was readily detected in a long-term labelled culture of proliferating REF52 cells (Fig. 3*a*),

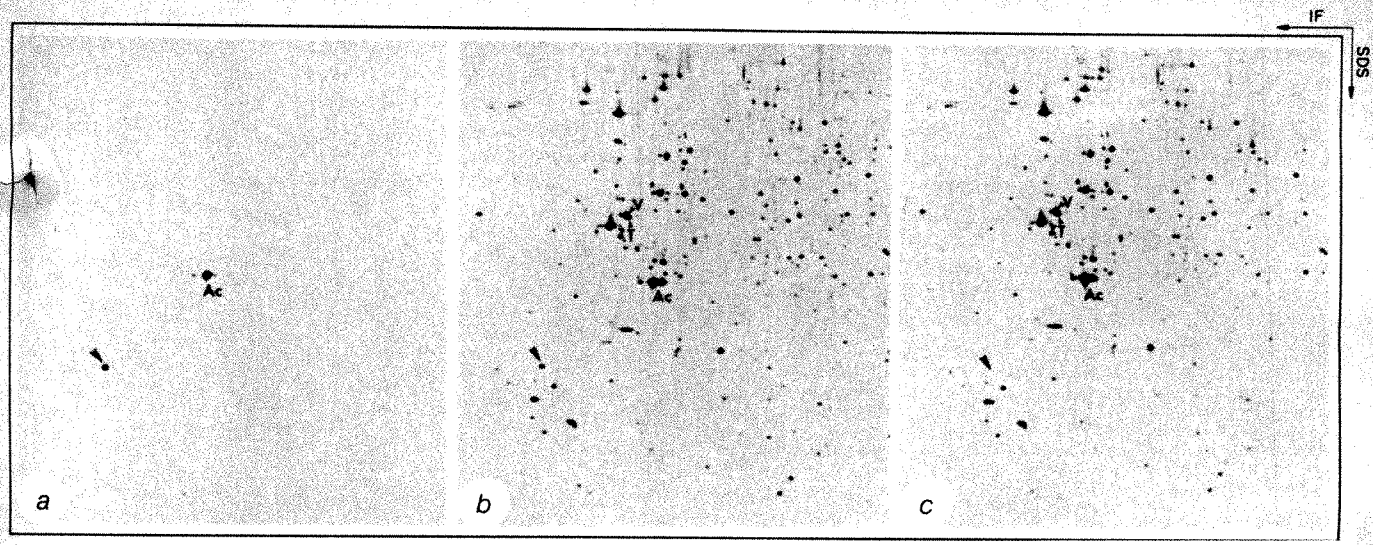

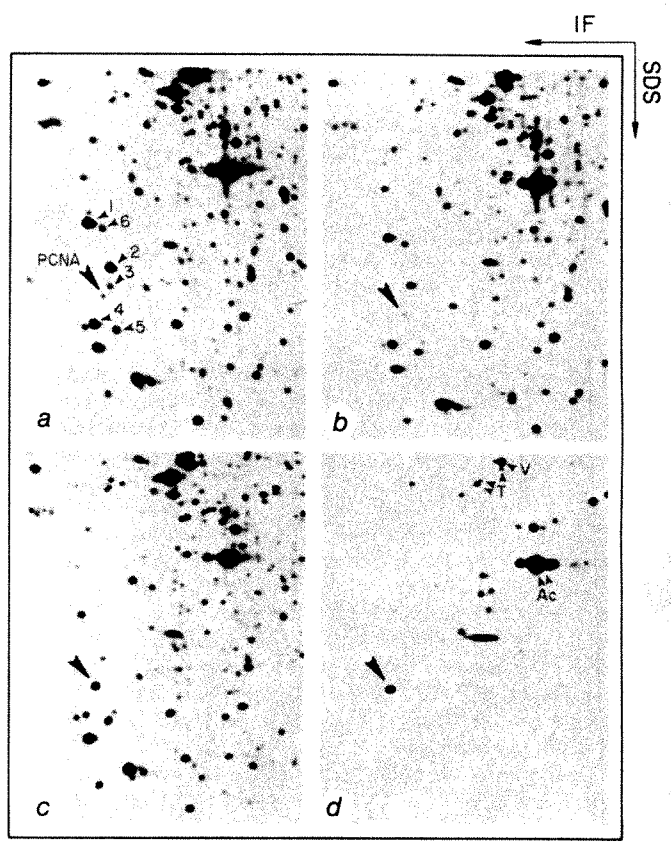

Fig. 2 Identification of PCNA in a two-dimensional gel. PCNA was precipitated from a HeLa cell extract as described in Fig. 1 legend. Proteins of the immunoprecipitate (*a*), the original extract (*b*) and the extract cleared of PCNA by anti-PCNA antibody (*c*), were resolved in two-dimensional gels using *p*H 3.5–10 LKB ampholytes in the first dimension (IF) and 10% acrylamide/SDS in the second dimension (SDS). Gels *b* and *c* were loaded with 500,000 d.p.m. of labelled protein and exposed for 9 days; gel *a* was loaded with 5,800 d.p.m. of labelled protein and exposed for 7 days. All gels shown were processed for fluorography[17] and exposed to XS-1 film. Arrowheads indicate the position of the major PCNA spot. The actin (Ac), vimentin (V) and tubulin (T) spots are also indicated. Actin is precipitated nonspecifically by both anti-PCNA and control sera, in amounts that vary between experiments. The gel shown in *a* contains actin serving as internal marker.

Fig. 3 (Right) PCNA in normal and transformed rat cells and purified nuclei. Proteins of proliferating REF52 cells 3 days after plating (*a*), quiescent REF52 cells 8 days after plating (*b*) and dividing REF52-AG6 cells 3 days after plating (*c*) were labelled for 24 h with ^{35}S-methionine and resolved in two-dimensional gels as in Fig. 2. Nuclear proteins from REF52-WT6 cells labelled for 2 h with ^{35}S-methionine were resolved in a similar gel (*d*). Nuclei were prepared by the method of Fleischer and Kervina[18]. REF52-WT6 cells are SV40-transformed REF52 cells[11], and REF52-AG6 cells are REF52-WT6 cells selected for growth in soft agar. Approximately 300,000 d.p.m. of labelled protein were applied to each gel. Gels *a*–*c* were exposed for 17 days and gel *d* for 4 days. The proteins indicated are the major PCNA spot (large arrowheads), actin (Ac), vimentin (V), tubulin (T) and tropomyosins 1–6 (numbers in *a*). The tropomyosin forms and their changes on transformation have been described elsewhere[12,19,20]. Quantitation was carried out using the QUEST system for computerized analysis of two-dimensional gels[21]. Each film was scanned using an Optronics P-1000 densitometer, and the spots were detected and integrated by the image analysis programs. Each film was calibrated[22] so that measurements of film density could be converted to d.p.m. per unit area before spot integration. The integrated d.p.m. for each spot was divided by the total trichloroacetic acid-precipitable d.p.m. applied to the gel. For the protein samples resolved in *a*–*c*, the proportion of total applied d.p.m. found in the PCNA spots was 0.014%, 0.008% and 0.067%, respectively.

but it was not a major protein constituent. It was also detectable in a resting culture of normal REF52 cells (Fig. 3*b*), although its level at quiescence was about half that in dividing cells. On the other hand, subconfluent SV40-transformed cells (Fig. 3*c*) contained about fivefold more PCNA than normal dividing REF52 cells (Fig. 3*a*). The magnitude of this increase, one of the largest inductions seen on transformation of REF52 cells by SV40 (data not shown), makes it unlikely that the higher level of PCNA in the transformed cells is due simply to their slightly shorter generation time. Furthermore, pulse-labelling experiments show that the rate of PCNA synthesis is elevated in all transformed lines examined, including cells transformed by SV40, adenovirus type 5 and Kirsten murine sarcoma virus[12].

In both HeLa cells (not shown) and SV40-transformed REF52 cells (Fig. 3*d*), PCNA was a major component of the nuclear fraction. It was more prominent in the nuclear pattern than in the whole cell protein pattern (Fig. 3*c*), unlike cytoplasmic components such as the tubulins and vimentin which were detectable but not enriched in the nuclei. However, the enrichment of PCNA in the nuclear fraction was not as great as that seen for certain other nuclear proteins. Indeed, some PCNA was detected in the cytoplasmic fraction of these cells (not shown), but in view of the overwhelmingly nuclear staining seen by immunofluorescence[2,3] this may represent a partial leaching from the nucleus during cell fractionation rather than a distribution between the two cellular compartments *in vivo*. Like its human counterpart, the rat PCNA spot was accompanied by a more acidic satellite spot. The ratio of the two forms did not vary substantially as a function of growth rate or subcellular fractionation, and the significance of this minor form is unclear.

These results demonstrate that PCNA is identical with cyclin in subcellular localization, electrophoretic behaviour and

peptide composition, as well as in biological properties. We suggest that the name PCNA be used in future, as it is the earlier nomenclature and the term cyclin has recently become ambiguous[13]. As shown here and elsewhere[3–9,12], the level of the protein falls in resting cells and, conversely, it becomes particularly prominent in transformed and tumour cells. Fluctuating PCNA levels have probably also been observed in other studies of transformed[14] and serum-stimulated[15] cells, but in these cases definite identification of PCNA is lacking. Although its function remains obscure, correlation of the previously unlinked reports on this transformation-sensitive and cell cycle-associated nuclear protein may yield illuminating clues. In this regard, it is intriguing that the maximal synthesis of PCNA appears to coincide with its accumulation in the nucleolus, preceding the peak of DNA synthesis[3,7]. The availability of relatively monospecific antibodies to PCNA should facilitate exploration of its connection with the nucleolus, cell division and transformation.

We thank C. Bunn, C. Herrmann, P. Smith and L. Cascio for their help, G. R. V. Hughes and E. M. Tan for serum samples, and S. J. Fey, P. Mose Larsen and J. Celis for comparison of protein samples by two-dimensional gel electrophoresis. This work was supported by NCI grant 13106 and a NATO travel grant.

Synthesis of biologically active rat transforming growth factor I

James P. Tam*, Hans Marquardt‡, Daniel F. Rosberger*, Tai Wai Wong* & George J. Todaro†‡

The hypothesis that some transformed cells produce endogenous transforming growth factors (TGFs) has been supported by isolation of peptide factors from transformed cells[1–5]. One group of TGFs, TGF-I, produced only by transformed cells, displays sequence homology with the functionally related mouse submaxillary epidermal growth factor (mEGF)[5]. Both TGF-I and mEGF exhibit similar activities in competition for binding to the EGF receptor, stimulation of DNA synthesis and cell growth. Another group of TGFs, TGF-II (also known as TGF_β)[2], present both in normal and transformed cells, is structurally and functionally unrelated to TGF-I or EGF, and does not compete for binding to the EGF receptor or induce cell growth. However, TGF-I or EGF in the presence of TGF-II produces a synergistic effect that is responsible for the observed phenotypic transformation of NRK fibroblasts[4]. The complete amino acid sequence of rat TGF-I (rTGF-I) from transformed Fischer rat embryo fibroblasts, has recently been determined[5]. Using this proposed sequence, we have now prepared synthetic rTGF-I by the solid-phase synthesis method and find that it exhibits chemical and biological properties indistinguishable from those of natural rTGF-I. Since synthetic rTGF-I is free of any biological contaminants, our findings provide independent evidence that rTGF-I is an active principle in the transformation of cells[6].

Rat TGF-I purified from the conditioned medium of Fisher rat embryo fibroblasts transformed by feline sarcoma virus is a single peptide chain containing 50 amino acid residues and 3 disulphide linkages. The primary structure was determined by Edman degradation in a gas-phase microsequencer to be[5]: H-Val-Val-Ser-His-Phe-Asn-Lys-Cys-Pro-Asp-Ser-His-Thr-Gln-Tyr-Cys-Phe-His-Gly-Thr-Cys-Arg-Phe-Leu-Val-Gln-Glu-Glu-Lys-Pro-Ala-Cys-Val-Cys-His-Ser-Gly-Tyr-Val-Gly-Val-Arg-Cys-Glu-His-Ala-Asp-Leu-Leu-Ala-OH.

The chemical synthesis of rTGF-I was performed manually by the stepwise solid-phase approach, following the general principles described by Merrifield[7]. We adopted the differential acid-labile protecting group strategy, using the conventional combination of t-butyloxycarbonyl for the N^α-amino terminus and benzyl alcohol derivatives for the side chains. An improved, more acid-stable benzyl ester linkage that anchored protected amino acids to the polymeric support was used to minimize loss of peptides during the repeated acid treatments[8]. Complete deprotection and removal of peptide from the resin was achieved by the new low–high HF method[9,10], which removed benzyl protecting groups by the S_N2 mechanism in dilute HF solution; this minimizes the serious side reactions due to carbocations generated in the conventional S_N1 deprotection method. It also minimizes the cysteinyl side reactions that can hamper the synthesis of proteins containing multiple disulphide linkages.

After HF treatment and before any purification, the crude and reduced synthetic rTGF-I was oxidized and regenerated by the mixed disulphide method in the presence of a combination of reduced and oxidized glutathione[11]. This avoided the formation of polymeric materials during purification. The regenerated, crude rTGF-I contained 40–50% of EGF radioreceptor and tyrosine-specific protein kinase activities when compared with natural rTGF-I. Crude synthetic rTGF-I was purified to homogeneity in three steps: (1) gel filtration on a BioGel P-10 column, (2) ion-exchange chromatography on a CM-Sephadex column and (3) preparative HPLC on a C_{18} reverse-phase column. Overall yield, based on starting loading of Ala to resin, was 31%.

In both reducing and nonreducing conditions, SDS-polyacrylamide gel electrophoresis of the purified synthetic rTGF-I gave a single band with an apparent molecular weight of 7,000. Amino acid analysis by 6M HCl and enzymatic hydrolysis provided the expected theoretical molar ratio of the proposed sequence. No free thiol was detected in synthetic rTGF-I by Ellman's method of sulphydryl determination[12], but thiolytic reduction produced the expected theoretical value of six cysteine residues. These findings support the conclusion that synthetic rTGF-I is a single-chain polypeptide containing six cysteines in disulphide linkages, which agrees with the expected chemical properties of natural rTGF-I. More importantly, synthetic rTGF-I co-eluted

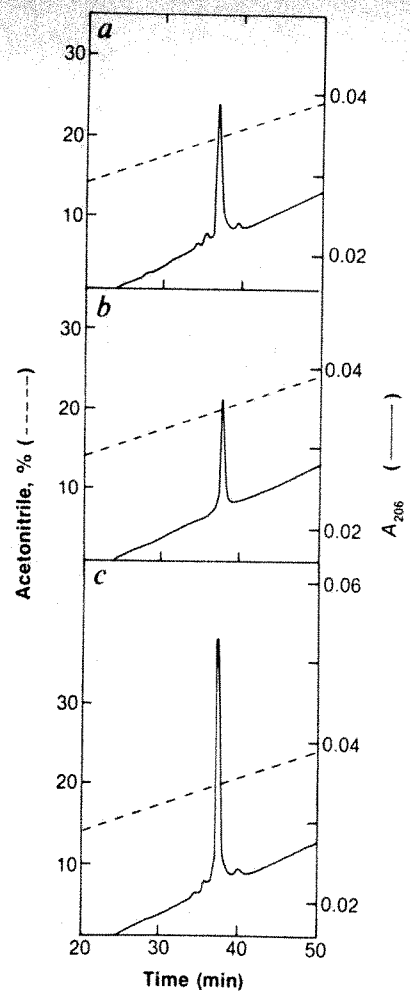

Fig. 1 HPLC of synthetic and natural rat TGF-I. *a*, 33.3 EGF-equivalents of natural rTGF-I; *b*, 26.3 EGF-equivalents of synthetic rTGF-I; *c*, 33.3 EGF-equivalents of natural rTGF-I and 26.3 EGF-equivalents of synthetic rTGF-I. Unit EGF equivalency is based on the displacement of ^{125}I-EGF in the radioreceptor assay. **Methods:** Crude synthetic rTGF-I was batch purified by gel filtration (P-10 column, 2.5 × 75 cm, elution with 1 M acetic acid), ion-exchange chromatography (CM-Sephadex column, 2.5 × 15 cm, linear *p*H gradient of 5.6–8.0 in 0.1 M NH_4OAc) and finally preparative HPLC (2.5 × 30 cm at a flow rate of 1.4 ml min^{-1}, eluting with a linear gradient of acetonitrile in 0.033% trifluoroacetic acid). Analytical HPLC was performed on a μBondapack C_{18} column (10 μm particle size, 0.39 × 30 cm, Waters Associates) at a flow rate of 1 ml min^{-1} at 40 °C. Peptides were eluted with a linear gradient of acetonitrile in 0.045% trifluoroacetic acid and were monitored at 206 nm.

with natural rTGF-I as a single symmetrical peak in C_{18} reverse-phase HPLC (Fig. 1).

Synthetic rTGF-I was compared with natural rTGF-I in three assays for the biological properties of the putative transforming growth factor. In the mitogen assay, TGF-I-stimulated growth of serum-deprived normal rat kidney cells was measured by the incorporation of ^{125}I-iododeoxyuridine. The soft agar assay, performed in the presence of fetal bovine serum and TGF-II, confirmed that the morphological and phenotypic alterations induced by rTGF-I could be quantified by colony formation in soft agar. The latter assay has been shown to correlate well with tumorigenicity[13]. Fetal bovine serum or TGF-II alone does not induce transformation of NRK cells in culture. Similarly, neither natural nor synthetic TGF-I produces such an effect in the absence of TGF-II. Both synthetic and natural rTGF-I displayed similar dose–response curves and half-maximal activities in these two assays (Fig. 2).

As rTGF-I is structurally related to EGF[14,15] and competes with mEGF for the binding of EGF receptors on cellular membranes[1], synthetic rTGF-I was compared with natural rTGF-I for binding on A431 human carcinoma cells. Again, the response and activities of the natural and synthetic rTGF-I were indistinguishable from each other (Fig. 3). The concentration required for 50% inhibition of ^{125}I-EGF binding was 3.5 and 4.1 nM for natural and synthetic rTGF-I, respectively. A consequence of TGF or EGF binding to the EGF membrane receptors is the stimulation of phosphorylation of tyrosine residues in synthetic peptides or endogenous substrates[16,17]. Synthetic rTGF-I was found to stimulate the phosphorylation of the synthetic angiotensinyl peptide substrate[18] with a half-maximal activity

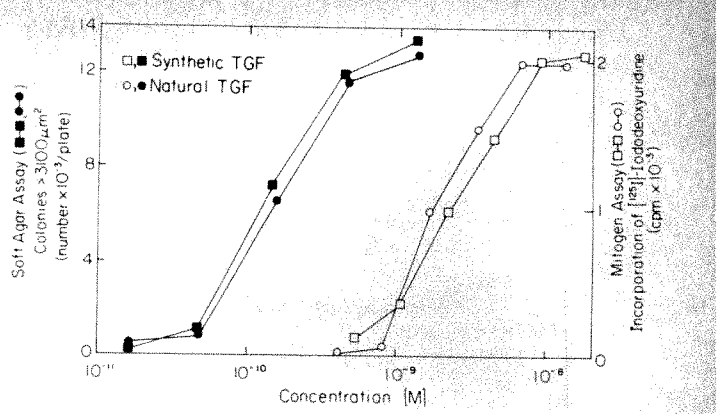

Fig. 2 Dose–response curves of mitogen and soft agar growth assays of synthetic and natural rTGF-I on normal rat kidney cells. The mitogen assay (open circles and squares) was performed in flat-bottom microwells (1 × 10^4 cells per well) in 100 μl Dulbecco's minimal essential medium with 10% heat-inactivated fetal bovine serum for 24 h and maintained in medium containing 0.1% fetal bovine serum for 7 days before the assay. Test samples were kept in 50 μl Waymouth medium[19], and [5-^{125}I]iodo-2′-deoxyuridine (^{125}I-IUdR, 2.5 μCi ml^{-1}, Amersham) was added for the final 24 h of culture[20]. Cells were washed and collected using a multiple harvester and counted in a γ-counter. Maximal ^{125}I-IUdR incorporation (2,048 c.p.m.) was 14-fold above control values (144 c.p.m.) without added mitogen. Values were corrected by subtracting ^{125}-I-IUdR incorporated into unstimulated control cultures. The assay for colony growth in soft agar (solid circles and squares)[21] using 49F fibroblast cells was performed as reported elsewhere[22], except that the crude platelet-derived murine TGF-II was added from stocks of 1 mg ml^{-1} in phosphate-buffered saline, containing 1 mg ml^{-1} bovine serum albumin. Stained colonies were quantified by number and size using a Bausch and Lomb image analyser[23]. The number of soft agar colonies (>3,100 μm^{-2}) in the presence of TGF-II was 96 per plate and was subtracted.

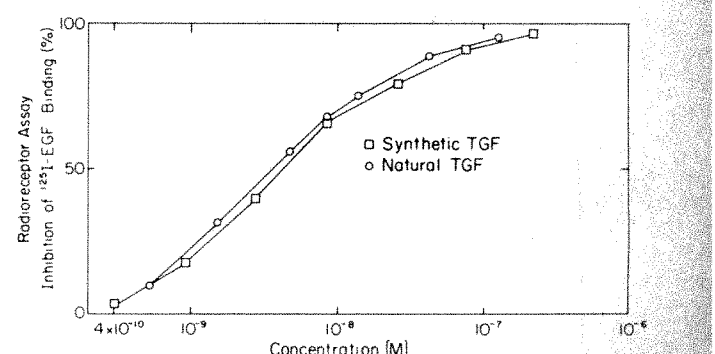

Fig. 3 Dose–response curve of radioreceptor assay of synthetic and natural rTGF-I. Purified mEFG was radiolabelled with Na ^{125}I by a modified chloramine-T method as described previously[5]. The ^{125}I-mEGF binding assay[1] was performed on subconfluent monolayers of formalin-fixed A431 cells[1]. Cells (8 × 10^3 per dish) were incubated with ^{125}I-mEGF (0.8 ng ml^{-1}, 82 μCi per μg) and unlabelled peptides at the indicated concentrations. The concentrations of natural and synthetic rTGF were quantified by amino acid analysis of companion aliquots. The ^{125}I-mEGF bound was determined, and nonspecific binding (binding in the presence of 2 μg ml^{-1} mEGF) was 2.4% and was subtracted. 100% binding corresponded to 10% of the input radioactivity.

of 0.3 nM (data not shown), comparable with the reported activity for natural rTGF-I[16].

In conclusion, we have demonstrated that synthetic rTGF-I possesses chemical and biological properties indistinguishable from those of natural rTGF-I. These findings, therefore, provide convincing evidence that the chemical structure of rat TGF-I is that proposed by sequencing studies[5]. Since synthetic rTGF-I is completely free of biological contaminants, its biological properties must be entirely due to the proposed structure of rat TGF-I, confirming the view that transformed cells produce endogenous growth stimulating polypeptide factors.

This research was supported by grants to J.P.T. from the Andrew W. Mellon Foundation.

Reversible inhibition of translation by *Xenopus* oocyte-specific proteins

Joel D. Richter*‡ & L. Dennis Smith†

* Department of Biochemistry, University of Tennessee, Knoxville, Tennessee 37996-0840, USA
† Department of Biological Sciences, Purdue University, West Lafayette, Indiana 47907, USA

A characteristic of growing oocytes of all animal species is the synthesis and accumulation of messenger RNA which is destined to be used primarily by the early embryo[1,2]. The mechanism(s) which regulates the translation of this maternal mRNA remains unknown. However, the inability of the oocyte to translate all of its putative mRNA has been attributed to at least three limitations: (1) The rate of translation is limited by the availability of components of the translational apparatus other than mRNA[3,4], (2) the structural organization of the mRNA prevents translation[5,6], and (3) proteins associated with the mRNA prevent translation[7,8]. Several investigators have suggested that proteins associated with maternal mRNA suppress translation in sea urchin eggs[7–10], although others claim that such results may be due to experimental artefacts[11,12]. Oocyte-specific proteins have been identified in association with non-translating poly(A)$^+$ mRNAs from *Xenopus laevis* oocytes[13–16], and we report here that when these proteins are reconstituted with mRNAs *in vitro* the translation of the mRNAs *in vitro* is reversibly repressed. The implication is that these proteins are involved in the regulation of translation of stored maternal mRNAs.

Recent studies have demonstrated that RNAs and proteins may be reconstituted faithfully *in vitro* (for example, refs 17–19).

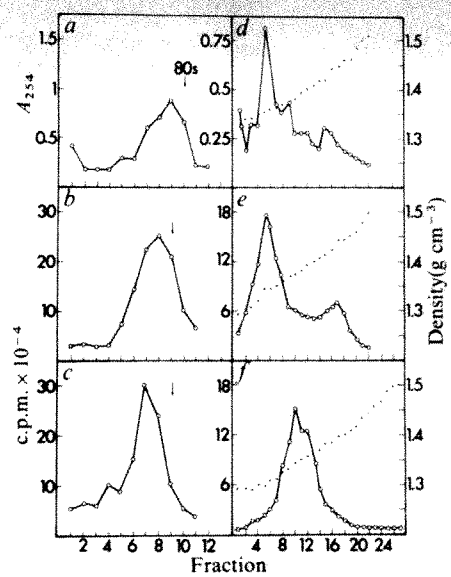

Fig. 1 Centrifugation of native and reconstituted RNPs. Formaldehyde-fixed native RNPs from oocytes were centrifuged through a sucrose gradient, fractionated and the absorbance at 254 nm in each fraction was determined (*a*). The fractions corresponding to 40–60S (fractions 8, 9) were collected, dialysed and centrifuged through a CsCl gradient. Fractions (0.2 ml) were collected and absorbance at 254 nm was determined, as was the density which was calculated from refractive index (*d*). Iodinated poly(A) RNA from stage 1–2 oocytes and rabbit globin mRNA were reconstituted with the RNA binding proteins and were centrifuged through sucrose gradients (poly(A) RNP (*b*); globin mRNP (*c*)). The 40–60S fractions from these gradients were then collected, fixed and centrifuged on CsCl gradients (poly(A) RNP (*e*); globin RNP (*f*)). Values for radioactivity (○–○) and density (···) are shown. The arrow indicates where the 80S monosome sedimented.

Methods: Stage 1–2 *Xenopus* oocytes were homogenized in polysome buffer (0.3 M KCl, 2 mM $MgCl_2$, 20 mM Tris-HCl *p*H 7.4, 4 μg ml^{-1} polyvinyl sulphate, 0.01% diethylpyrocarbonate, 10 μg ml^{-1} cycloheximide and 0.5% Nonidet P-40) and the post-mitochondrial supernatant was then centrifuged through a 5–30% sucrose gradient in buffer in an SW41 tube for 3 h at 4 °C at 34,000 r.p.m. The gradient fractions corresponding to the 40–60S region were collected, dialysed against 10 mM phosphate buffer *p*H 7.2, and then fixed in phosphate-buffered 4% formaldehyde for 2 h at 4 °C[27]. These particles then were suspended in 10 mM HEPES *p*H 7.5 and 0.5 M NaCl and applied to an oligo-d(T) cellulose column (P-L Biochemicals, type 7). The column was washed in high salt buffer until no UV(A_{254})-absorbing material was detected in the eluate. The poly(A) RNPs were then eluted in 10 mM HEPES *p*H 7.5. Fixed RNPs were centrifuged through preformed 30–60% CcCl gradients[28] for 12 h in an SW 50.1 tube at 33,000 r.p.m. at 4 °C. Poly(A) RNA and globin mRNA were iodinated by the $TlCl_3$ method as described previously[6,16].

To obtain oocyte protein for reconstitution experiments, stage 1–2 *Xenopus* oocytes were homogenized and the ribonucleoprotein (RNP) particles sedimenting through a sucrose gradient to a 40–60S fraction were collected. The proteins from such RNPs were purified further by elution from a phosphocellulose column in high salt as reported previously[16]. The five major proteins in this fraction have molecular weights of 50,000–94,000, bind poly(A)$^+$ RNA with high affinity and are oocyte-specific[16]. For reconstitution studies, these proteins were mixed with ^{125}I-labelled poly(A) RNA from stage 1–2 oocytes and compared with native particles by sucrose gradient and CsCl gradient centrifugation. Reconstituted poly(A) RNP particles sedimented primarily at 40–60S (Fig. 1*b*), as did the native particles originally used to obtain the proteins used for reconstitution (Fig. 1*a*). Most of the reconstituted poly(A) RNP particles which sedimented at 40–60S (Fig. 1*b*) exhibited a buoyant density in CsCl of 1.34 g cm^{-3}, with a minor peak at a density of 1.44 g cm^{-3} (Fig. 1*e*). These values again are virtually identical with those obtained with native particles which exhibited a peak

Table 1 Relative translatability of reconstituted globin mRNA in injected oocytes

	Synthesis of globin relative to injected pure globin mRNA (%)						
	Expt no.						
	1	2	3	4	5	6	$x \pm$ s.d.
Pure globin mRNA	100	100	100	100	100	100	100 ± 0
Globin mRNA + histones	140	139	133	111	—	—	131 ± 12
Globin mRNA + ribosomal proteins	—	150	155	120	—	—	142 ± 15
Globin mRNA + basic liver proteins	—	105	137	101	—	—	114 ± 16
Globin mRNA + basic leg muscle proteins	—	—	—	—	—	97	97
Globin mRNA + basic heart proteins	—	—	—	—	—	96	96
Globin mRNA + oocyte RNA binding proteins	5	30	37	11	40	37	25 ± 17

Expt 1: Four stage VI *Xenopus* oocytes were injected with 10 ng of pure globin mRNA, 10 ng of globin mRNA reconstituted with 10 ng calf thymus histones, or 10 ng of oocyte binding proteins (preparation 1) prepared as follows. Stage 1–2 *Xenopus* oocytes were homogenized and the post-mitochondrial supernatant was centrifuged through a sucrose gradient[16]. The RNPs sedimenting to the 40–60S fraction were collected and applied to a phosphocellulose column. The proteins eluting in 1–2 M NaCl were used for reconstitution[16]. Reconstitution conditions were 30–60 min on ice in 10 mM Tris-HCl *p*H 7.5 and 50 mM NaCl. Oocytes were cultured for 12 h in OR-2 medium[24] and then injected with ^{3}H-leucine[4]. Oocytes were then cultured for 1 h. The radioactive proteins were collected[4], electrophoresed on a SDS-12.5% polyacrylamide gel and the radioactive globin band was cut out, oxidized and the radioactivity determined by liquid scintillation spectrometry[4]. **Expts 2–6:** Five oocytes were injected with 3 ng pure globin mRNA, or globin mRNA reconstituted with 30 ng of calf thymus histones, *Xenopus* oocyte ribosomal proteins (that is, *Xenopus* stage VI oocyte proteins extracted from RNP particles with high salt (2 M NaCl) which sedimented at 80S and had a molecular weight <60,000 as determined by gel filtration), *Xenopus* liver, leg muscle and heart proteins prepared in the same way as the oocyte RNA binding proteins[16], or *Xenopus* stage 1–2 oocyte RNA binding proteins[16]. Oocytes were cultured for 18 h in modified Barth's saline[25] and then injected with ^{35}S-methionine[26]. Oocytes were cultured for an additional hour and the protein prepared as described previously[4]. The relative amount of globin synthesis was determined by densitometry of autoradiograms or by direct quantitation of the radioactivity in the putative globin band. Expt 2 used oocyte RNA binding protein preparation number 2, expt 3 used preparation 3, expt 4 used preparation 4 and expt 5 used preparation 5. The autoradiogram shown in Fig. 2 was taken from expt 4.

density of 1.36 g cm^{-3}, with a minor peak at 1.42 g cm^{-3} (Fig. 1*d*). Similar experiments were performed with ^{125}I-labelled rabbit globin mRNA. Reconstituted globin mRNP also sedimented in the 40–60S region of the gradient (Fig. 1*c*) and had a peak buoyant density of 1.34 g cm^{-3} (Fig. 1*f*). Using the formula of Spirin[20], the native RNPs had a protein to RNA mass ratio of 4.5 : 1, very similar to a previous estimate of oocyte poly(A) RNP protein to RNA mass ratio of 4 : 1 (ref. 14). The reconstituted poly(A) RNP and globin RNP had protein to RNA mass ratios of 5.5 : 1. Other experiments (data not shown) demonstrated that that same ratio was obtained even with a 10-fold greater amount of protein in the initial incubation with the RNA. Thus, based on the physical characteristic we have measured, the reconstituted RNPs appear to be very similar to native RNPs.

To test the translatability of reconstituted RNPs *in vitro*, we have injected RNPs into *Xenopus* oocytes. Since the endogenous mRNAs being translated represent a subset of total poly(A) RNA in the oocyte, the translation of reconstituted poly(A) RNAs would be difficult to assess quantitatively[6]. Accordingly, we have determined whether the oocyte-specific RNA binding proteins affect the translation of globin mRNA. Figure 2 shows an SDS gel autoradiogram of the proteins synthesized in mRNP-injected oocytes. When pure globin mRNA was injected, globin synthesis was readily detected (Fig. 2, lane 2). However, when globin mRNA was reconstituted with oocyte proteins before injection, no globin synthesis was apparent (lane 3). Globin mRNA reconstituted with other basic proteins such as histone (lane 4) or ribosomal proteins (lane 5) was still translatable. Furthermore, reconstitution of globin mRNA with basic liver proteins (lane 6), extracted from the 40–60S particle fraction and purified as described for the oocyte proteins, did not prevent translation.

Table 1 summarizes several experiments to determine the amount of globin synthesized as a consequence of reconstitution with protein from several sources. The reconstitution of globin mRNA with histones or ribosomal proteins or proteins from frog liver, muscle or heart prepared in a manner identical with the oocyte proteins described above, results in as much as 42% enhancement of globin synthesis. Examination of the protein species in these various fractions reveals that those present in the oocyte are absent from the somatic tissues (data not shown; see also ref. 16). As most globin mRNA turns over following injection[4], it is likely that the non-oocyte proteins protect the mRNA from oocyte nucleases until it is loaded onto polysomes. As Fig. 2 indicates, the oocyte-specific proteins inhibit globin synthesis in injected oocytes. On average, one-quarter as much globin is synthesized when the mRNA is reconstituted with the oocyte proteins as when pure mRNA is injected. Although there was some variation between preparations, the protein always inhibited globin mRNA translation by at least 60%.

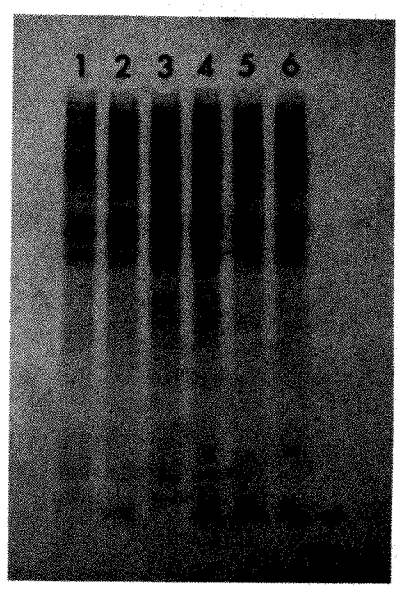

Fig. 2 Autoradiogram of proteins synthesized in mRNP-injected oocytes. Oocytes were injected with 5 ng of pure rabbit globin mRNA (lane 2), or 5 ng globin mRNA reconstituted with 30 ng of stage 1–2 oocyte proteins (lane 3), 30 ng of histones (lane 4), 30 ng of ribosomal proteins (lane 5), or 30 ng basic liver proteins (lane 6). Control oocytes were not injected (lane 1).
Methods: Conditions for reconstitution are described in Table 1 legend. Oocytes were injected with mRNA or mRNP, cultured for 18 h, injected with ^{35}S-methionine (Amersham; 1,220 Ci mmol^{-1}) and cultured for an additional hour. Oocytes were homogenized in 50 mM NaCl, the protein was collected[4], and resolved by SDS-12.5% polyacrylamide gel electrophoresis.

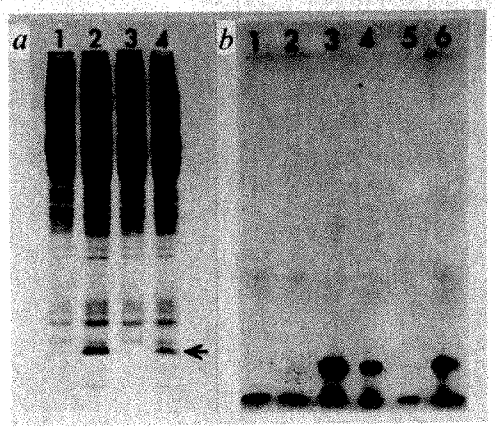

Fig. 3 The inhibition of translation by oocyte-specific proteins is reversible. *a*, Five noninjected oocytes (lane 1), or oocytes injected with 5 ng pure globin mRNA (lane 2), 5 ng globin mRNA reconstituted with oocyte proteins (lane 3), or 5 ng globin mRNA reconstituted with oocyte proteins and then deproteinized (lane 4), were cultured and then injected with ^{35}S-methionine. The resulting radioactive proteins were resolved by SDS-gel electrophoresis and fluorography. *b*, Synthesis of reconstituted globin mRNA in a wheat germ lysate. Lane 1, no mRNA added; lane 2, 1 μg globin mRNA reconstituted with 1 μg of oocyte proteins and then digested with 1 μg ml^{-1} RNase A; lane 3, 1 μg pure globin mRNA; lane 4, 1 μg globin mRNA reconstituted with 1 μg oocyte protein; lane 5, 1 μg globin mRNA reconstituted with 9 μg oocyte protein; lane 6, 1 μg globin mRNA reconstituted with 9 μg oocyte protein and then deproteinized.

Methods: Globin mRNA and oocyte proteins were reconstituted as described in Table 1 legend (expt 4). One-half of the mixture (as well as pure RNA) was extracted once with buffer(10 mM Tris-HCl *p*H, 0.1% SDS)-saturated phenol/chloroform/isoamyl alcohol (25:24:1) and once with chloroform/isoamyl alcohol (99:1). The aqueous phases were then injected without further modification. The efficiency of recovery was ~80% based on the extraction of reconstituted ^{125}I-globin mRNA. Following RNP or RNA injection, oocytes were cultured for 18 h and then injected with ^{35}S-methionine. The resulting radioactive proteins were collected and analysed as described for Fig. 2. The wheat germ lysate (BRL) reaction volume was 30 μl containing 5 μCi of ^{35}S-methionine. The reaction was carried out at 25 °C for 1 h. Deproteinization and the analysis of the radioactive proteins were as described above.

We have assayed for ribonuclease contamination in the oocyte protein preparation. ^{32}P-labelled total oocyte RNA was mixed with the oocyte proteins and the RNA was resolved by denaturing agarose gel electrophoresis and autoradiography. In contrast to pure ^{32}P-labelled oocyte RNA, no degradation of the reconstituted RNA was observed (data not shown). In addition, total RNA from oocytes injected with globin mRNA reconstituted with the oocyte proteins was extracted and used for an RNA gel blot. Using ^{32}P-labelled globin cDNA as the probe, only full-size globin mRNA was evident when pure or reconstituted globin mRNA was injected (data not shown). However, the possibility remained that the oocyte proteins rendered the mRNA nontranslatable by some permanent modification not detected by the methods described above. Therefore, we determined whether reconstituted globin mRNA may become translatable following deproteinization. Figure 3*a* again demonstrates that globin synthesis was detected when pure mRNA (lane 2), but not reconstituted mRNA (lane 3), was injected into oocytes. When reconstituted mRNA was deproteinized by phenol and chloroform and then injected, globin synthesis was evident (lane 4). The synthesis of globin in oocytes injected with deproteinized reconstituted globin mRNA was always 20–40% lower than when the pure mRNA was injected. This difference cannot be accounted for by a very low recovery of the mRNA (see Fig. 3 legend) and possibly results from incomplete deproteinization. Nonetheless, we do conclude that the oocyte proteins reversibly inhibit the translation of injected mRNA in injected oocytes.

The ability of the oocyte proteins to inhibit translation of globin mRNA *in vitro* was also tested (Fig. 3*b*). Whereas the translation of globin mRNA was very efficient in a wheat germ lysate (lane 3), that of mRNA reconstituted with increasing amounts of the oocyte proteins became progressively more inefficient (lanes 4, 5).

We have conducted preliminary experiments which suggest that mRNP unmasking can occur *in vivo*. These experiments are based on the observation that in oocytes induced to undergo maturation by progesterone, general protein synthesis approximately doubles[21] due to the recruitment of previously untranslated mRNA onto polysomes[22]. If this recruitment involves mRNP unmasking, it might be expected that injected globin mRNP would become translatable in the mature oocyte. When such experiments were done in oocytes injected with reconstituted globin mRNP and then induced to mature, there was a 3.5-fold increase in radioactivity in the globin band. However, in noninjected oocytes which had undergone maturation, a 2.9-fold increase in radioactivity occurred in the region of an SDS gel where globin would be expected to migrate. Although we tentatively attribute this difference to globin mRNP unmasking, the fact that the synthesis of endogenous proteins partially obscures our quantitation of globin synthesis suggests the need for a more rigorous study to confirm these observations.

The present study demonstrates that oocyte-specific proteins extractable from native RNPs may be reconstituted with mRNAs *in vitro* to form particles which resemble native RNPs. Further, these proteins can reversibly repress the translation of the mRNA *in vivo* (as well as *in vitro*). Several control experiments support the view that this result is not due to nonspecific inhibition. Thus, we now have a system whereby proteins can be used in reconstitution experiments and their ability to alter translation and/or stability of mRNA in *in vivo* conditions may be investigated. In this connection, a monoclonal antibody to an oocyte RNA binding protein has been isolated[23]. Thus, with this and other monoclonal antibodies, individual proteins may be isolated and reconstituted with mRNA, and the function of each assessed.

We thank Brad Pearman for the densitometric determinations. This work was supported by NIH biomedical research support grant RR-07088-15 and NIH grant GM 32559 to J.D.R. and NIH grant HD 04229 to L.D.S.

DETERMINANTS OF HEALTH LEVELS IN DEVELOPING COUNTRIES

by **G.E. Cumper,** *Ross Institute, London School of Hygiene and Tropical Medicine*

If health in the developing world is to be improved without waiting for the slow processes of economic growth, we need to know what are the specific factors that promote national health, and how far they can be manipulated as a matter of national and international health policy. Many such factors — medical, environmental, biological, social, economic and political — can be tentatively identified on general grounds or on the basis of evidence at the individual or community level. The study described in this book tests many of these identifications against international statistical evidence. Regression techniques are applied to a data base covering 160 countries and incorporating data on mortality rates, inputs to the health services and other health-related factors.

THE CONTRIBUTION OF GENETICS TO THE STUDY OF PARASITIC PROTOZOA

by **D. Walliker,** *University of Edinburgh, Institute of Animal Genetics, Scotland*

This is the first book on the genetics of parasitic protozoa, now an expanding field of study. The book concentrates on a few protozoa which cause major diseases — malaria parasites, trypanosomes (the cause of sleeping sickness) and coccidia (of veterinary importance), and describes how genetic studies can contribute to the planning of effective control measures.

Tropical Medicine Research Studies Series No. 4.

086380 005 X 228pp October'83 £29.50

". . . an authoritative guide to the present state of a rapidly expanding subject much of the expansion being due to the work of the author himself."

THE BIOLOGY OF ENTAMOEBA HISTOLYTICA

by **A. Martinez-Palomo,** *Department of Cell Biology, Centre for Research and Advanced Studies, National Polytechnic Institute, Mexico City*

Invasive amebiasis is a major health problem in regions of the world where inadequate sanitary conditions together with poverty, ignorance and overcrowding, and the prevalence of highly virulent strains of *E.histolytica* combine to sustain a high level of intestinal amebiasis in children and of liver abscesses in adults. This book is a much-needed review which evaluates the present state of knowledge of the biology of the parasite, information previously dispersed in books, journals and proceedings of unrelated medical and biological specialties.

Tropical Medicine Research Studies Series, No. 2

Contents: Preface; Introduction; Cell Biology; Biochemistry; Species of *Entamoeba*; Immunology of Amebiasis; Parasite Factors of Virulence; Some Unsolved Problems in Amebiasis Related to the Biology of the Parasite; References; Selected Monographs and Articles on Amebiasis.

0471 10404 3 174pp June'82 £17.85

". . . must be regarded as a "gem" for both the student and long term researcher of intestinal amoebae."

REVIEW FOR BUREAU OF HYGIENE AND TROPICAL DISEASES 1982

"This book is highly recommended; it is a classic contribution to the field of enteric, parasitic protozoa."

Eugene C. Weinbach, TRENDS IN BIOCHEMICAL SCIENCES, April 1983

PERSPECTIVES IN TRYPANOSOMIASIS RESEARCH

Proceedings of the Twenty-First Trypanosomiasis Seminar, London, 24th September 1981

edited by **J.R. Baker,** *Institute of Terrestrial Ecology, Cambridge*

Proceedings of the 21st Seminar of Trypanosomiasis , held on 24th September 1981 in London, organised by the British Society for Parasitology, held at accommodation provided by the Royal Society of Tropical Medicine and Hygiene. The general theme of the meeting was current inadequacies in trypanosomiasis, and tsetse research and control; there were three sessions on trypanosomiasis, chemotherapy and tsetse. The book contains the substance of the talks by the invited speakers.

Tropical Medicine Research Studies Series, No. 3

0471 10478 7 114pp September'82 £13.60

". . . a well-written and valuable book. It should be added to the library of anyone interested in the epidemiology and control of the trypanosomiases.

AMERICAN JOURNAL OF TROPICAL MEDICINE AND HYGIENE July 1983

SCHISTOSOMA MANSONI

The Parasite Surface in Relation to Host Immunity

by **D.J. McLaren,** *Division of Parasitology, The National Institute for Medical Research, London*

This monograph considers in detail the structural and immunological properties of the developing parasite surface and its relationship to parasite survival in the immunocompetent host. It draws together the established and very recent information on the morphological, immunological and physiological properties of the developing schistosome surface, so that the reader may be immediately aware of the interrelationships of these various disciplines.

Tropical Medicine Research Studies Series, No. 1

0471 27869 6 246pp November'80 £26.50

"Dr. McLaren writes clearly and with considerable authority on her subject. The book will be required reading for all serious researchers in parasite immunology."

Guy Ourisson

Pour Sauver l'Université. By Laurent Schwartz.
Editions du Seuil, 27 rue Jacob, F-75261, Paris Cedex 06: 1983. Pp.123. Pbk FF 49.

LAURENT Schwartz, a Fields medallist, is certainly the most outspoken mathematician in France. For years, he has persistently taken strong public stands against colonialism in Algeria, for human rights and civic liberties in the USSR, for progress through education and scientific research, and for the electoral victory of the Left in France. So when he writes of the reforms currently underway in French universities that "mediocrity will take precedence over quality, diversity will disappear into drabness, responsible decisions will be made impossible by irresponsible politicking", everybody in French academic circles is likely to listen to what he has to say.

Schwartz sets the tone unambiguously: "I hope the present socialist experiment will succeed. I want to help the Government, and this is why I criticize it". Despite this clear warning, I had expected, when this book appeared last autumn, that his analysis — expert, explicit and caustic — would become political TNT graciously handed to the opposition parties. This, in fact, has not really been the case; when the book came out, the opposition had already shifted its attention to more popular disputes than the Savary reform. Such is the prodigious capacity of Gallic organizations to lose interest once a law has been passed and all that remains to do is to try to apply it.

Pour Sauver l'Université has now been read by everybody in French academic circles; at least, the reviews have been read. The book has helped to focus the final round of discussions in Parliament on some of the key points of the Savary reform. It has helped in generating, in the universities, new trends and new view points. It has been a useful book, but one which has in part estranged Schwartz's own Left, the author being branded as an elitist, an arch-enemy of the Unions and the avowed leader of the "mandarins" (in France, the reactionary professors). Schwartz's influence has rallied around the slogan "Qualité de la science" lists of candidates, politically non-aligned and independent of the trade unions, in recent elections to various national "Comités" — and his name has helped these candidates to be elected *en masse*. So the impact of this little book in France has been great. But who outside of France would discover it to be worth reading?

What is found in *Pour Sauver l'Université* ranges from the specific to the general. I doubt if anybody outside France, except perhaps students of French education, would bear reading the chapter criticizing the new voting procedures chosen for the various bodies of university self-government (those same procedures which a few months later enabled "Qualité de la science" candidates to be elected in great numbers). I also doubt if anybody outside the French system would gain anything useful from the chapter describing the dual higher-education system in France, in which Grandes Ecoles thrive alongside universities, select supposedly the best students, in some areas monopolize the job market, nurture the industrial elite, and yet are in many cases appallingly alien to the very notions of innovation and of research. We French have to cope with this system, and try to adapt it to changing needs — but nobody else would gain from adopting it.

On the other hand, it is quite probable that a longer lasting interest could be found in the three remaining chapters: two on the virtues of selection of students, and on the way to organize it, and the last one on the interaction between teaching and research. These are real, general problems, common to many countries, and Schwartz has a very wide knowledge of the situation in the United States, in Great Britain and in Germany. His opinions therefore carry some weight. For instance, he gives a very lucid discussion of the fallacy equating free entry into universities with the democratization of higher education — particularly when students, once admitted, are not orientated towards fields adapted to their skills and thus in part towards the job market, but have to cope unassisted with examiners determined to let only the fittest survive. He also broadly defines conditions which would favour a genuine democratization of the higher education system — by setting ambitious goals for students and helping them to choose progressively the area in which they could excel, or at least do their best. Admittedly, this is the very philosophy of the Savary reform; but here, as in many other places in the book, Schwartz is more critical of what he fears will be made of these changes, by us his colleagues, than of the content of the new law itself. Obviously, he shares with me a certain scepticism of the real efficiency, in France, of a "definitive" law.

Students march through Paris in May last year in protest at the proposed reform of the nation's university system.

For foreign readers, however, probably the most informative chapter is the one devoted to research (more precisely, to remain in tune with the book's general theme, to the "Dangers Looming over Research"). This gives a good description of what really works well in French research (apart from Big Science): the unique symbiosis of the National Research Council (the Centre National de la Recherche Scientifique) and the universities, which might well be a worthwhile export item. Schwartz believes it is endangered; I do not, and I do not believe that any law can threaten it more than our natural tendency to divide Gallia into as many little fiefdoms as we can.

Anybody interested in understanding the currents now flowing in French academia, and shaping it anew, should read this short and intelligent book. A complementary audience might also include students of academic research as well as some sociologists and historians. But whatever their background, all readers should remember to place Schwartz's thesis within a general perspective of the French political situation in which it is rooted. □

Guy Ourisson is Professor of Chemistry at the Université Louis Pasteur in Strasbourg. From 1970 to 1975 he was President of the Université Louis Pasteur, and in 1981–1982 was Director-General of Higher Education and Research responsible to M. Savary.

The current issue of *Peptides*: vol 5, no. 2 (March/April), 1984, is devoted to recent progres in research on vaso-active intestinal polypeptide (VIP) and related peptides. The papers, based on presentations at the 1st international symposium on VIP, held in Brussels, September 13-16, 1983, deal with aspects of chemistry, biochemistry, anatomic localization, physiology, pathophysiology and clinical significance of VIP (and to some extent, secretin & PHI). Topics relate to the neuroendocrine, gastrointestinal, cardiovascular, respiratory, and reproductive systems.

Underwater illumination

M. J. Dring

Light and Photosynthesis in Aquatic Ecosystems.
By John T. O. Kirk.
Cambridge University Press: 1983.
Pp.401. £37.50, $74.50.

THERE are advantages and disadvantages in attempting to bridge the gap between two scientific subjects. Ideally, the bridge will provide a route for the two-way traffic of ideas and scientists; but if the two subjects are in very different states of development, it may result instead in a brain-drain from the weaker to the stronger subject.

By bringing together the physics of underwater light and the biology of aquatic photosynthesis, Dr Kirk's book seems more likely to produce the latter result. Part I ("The Underwater Light Field") constitutes such a superb manual for would-be modellers that it may well persuade many aquatic biologists that, given the availability of modern underwater irradiance meters and microcomputers, it is very much easier to measure light than to measure photosynthesis. Part II ("Photosynthesis in the Aquatic Environment"), on the other hand, creates the impression that biologists are still far from the position where they can make much use of the exact information about underwater light described in Part I. There is, therefore, little incentive for physicists to become involved with photosynthetic problems and to reciprocate the movement of biologists into their field. This is a familiar problem at the boundaries of biology and physics, but one which is accentuated to a possibly unnecessary degree by the contrast between the two parts of Dr Kirk's book.

Part I is rigorous, lucid and concise. A review of the optical properties of water leads into thorough accounts of what to measure and how to measure it, and how these measurements can be used to characterize fully the underwater light field. Biologists may wonder from time to time if they really need to know all of the details discussed, but Dr Kirk provides clear, complete answers to their commonest questions, together with valuable compilations of measurements from water bodies around the world. Here, at last, is the complete manual on underwater optics for biologists, which must become an essential reference for students of all photobiological processes underwater.

The excellence of Part I sets such a high standard that it may seem churlish to complain that Part II fails to live up to it. The problem lies partly in the nature of the subject matter — the physiology and ecology of diverse and variable organisms cannot be treated as rigorously as the physical properties of light and water — but also in the author's approach. Acknowledging that light is not the only controlling factor, he has attempted a reasonably comprehensive account of aquatic photosynthesis, in which few references to underwater optics are couched in more than general and qualitative terms. Consequently, those readers who know enough about aquatic photosynthesis to appreciate and benefit from Part I are liable to be disappointed by Part II. Instead of retracing the steps of other recent books and reviews, I feel that Dr Kirk should have tried to illustrate how our understanding of aquatic photosynthesis might be advanced by applying the knowledge of underwater light presented in Part I. Bridge builders must establish their bridgeheads before advancing into the hinterland. □

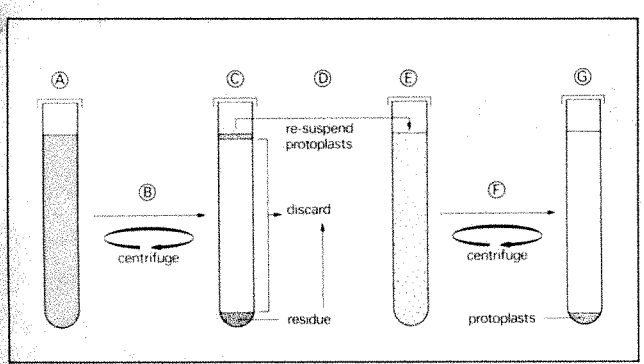
Seeing new light



Alan E. Shapiro

Optics after Newton: Theories of Light in Britain and Ireland, 1704–1840.
By Geoffrey Cantor.
Manchester University Press: 1984.
Pp.257. £20, $25.

THE traditional history of optics from the publication of Newton's *Opticks* in 1704 to 1840 runs roughly as follows. The Newtonian emission or projectile theory of light dominated the wave theory in the eighteenth century, which, however, was overall a "sterile" period for optical research. The wave theory began to gain the upper hand at the beginning of the nineteenth century, when Thomas Young discovered the principle of interference, although initially his work was unjustifiably ignored. Finally, within a decade of Augustin Fresnel's comprehensive formulation of the wave theory (1815–1825), that theory vanquished its rival.

Geoffrey Cantor's primary aim in *Optics after Newton* is to reinterpret many elements of this story. He rejects the "sterility" thesis for the eighteenth century; he adds a third major theory of light, fluid theories, in which light is conceived to be a subtle fluid of interacting particles — not independent projectiles — flowing from a luminous source; and he argues that Young's principle of interference was rejected because it was perceived to be part of his otherwise unoriginal wave theory of light. I find Cantor's reinterpretation to be largely unconvincing. The primary cause of this is that the author is more concerned with historiography than with the history of optics, which he

Protoplast Fusion

Genetic Engineering in Higher Plants

Editor: **R. Shoeman**

1984. 62 figures. Approx. 245 pages
(Monographs on Theoretical and Applied Genetics, Volume 8)
Cloth DM 148,–; approx. US $ 58.10. ISBN 3-540-13284-8

The book contains many results not previously available in English. Originally published in Russian in 1982, it was revised considerably and up-dated for this English edition.

Petunia

Editor: **K. C. Sink**

1984. 61 figures. Approx. 290 pages
(Monographs on Theoretical and Applied Genetics, Volume 9)
Cloth DM 98,–; approx. US $ 38.50. ISBN 3-540-13472-7

This book covers the classical aspects of *Petunia* biology as well as the more modern subjects of genetics and biochemistry of genes involved in floral pigmentation, molecular biology, haploidy, cell and anther culture, and protoplast fusion.

Embryology of Angiosperms

Editor: **B. M. Johri**

1984. 278 figures. Approx. 820 pages
Cloth DM 290,–; approx. US $ 113.70. ISBN 3-540-12739-9

Contents: Embryology: Then and Now. – The Microsporangium. – The Ovule. – The Female Gametophyte. – The Pollen Grain. – Fertilization. – The Endosperm. – The Embryo. – Polyembryony. – Gametophytic Apomixis. – Role of Polyploidy in Reproductive Organs and Tissues. – The Seed: Structure. – The Seed: Germination. – Embryology and Taxonomy. – Homologies and Phylogeny. – Experimental Embryology.

Cellular Interactions

Editors: **H.-F. Linskens, J. Heslop-Harrison**

1984. 198 figures. XVIII, 743 pages
(Encyclopedia of Plant Physiology, Volume 17)
Cloth DM 360,–; approx. US $ 141.20. ISBN 3-540-12738-0

Hormonal Regulation of Development II

The Functions of Hormones from the Level of the Cell to the Whole Plant

Editor: **T. K. Scott**

1984. 42 figures. Approx. 320 pages. (Encyclopedia of Plant Physiology, Volume 10)
Cloth DM 168,–; approx. US $ 65.90. ISBN 3-540-10196-9
20% discount for purchasers of Volumes 9, 10 and 11

Compartments in Algal Cells and Their Interaction

Editor: **W. Wiessner, D. Robinson, R. C. Starr**

1984. 136 figures. Approx. 265 pages. (Proceedings in Life Sciences)
Cloth DM 98,–; approx. US $ 38.50. ISBN 3-540-13318-6

T. L. Simpson

The Cell Biology of Sponges

1984. Approx. 220 figures. Approx. 585 pages
Cloth DM 258,–; approx. US $ 101.20. ISBN 3-540-90893-5

Well illustrated, fully documented and indexed, this book presents a fascinating survey and comprehensive, critical review of what we know about the cell structure, ultrastructure, cellular activities, physiology, and developmental processes in the phylum Porifera.

Hormonally Defined Media

A Tool in Cell Biology

Lectures and Posters Presented at the

tell your librarian . . .

first issue coming soon

BioEssays . . . is coming!

Editor: W. J. Whelan *University of Miami*

July 1984 will see the launch of this important new monthly journal, presenting the results of major discoveries at the very frontiers of molecular, cellular and developmental biology.

Published under the auspices of the International Council of Scientific Unions **BioEssays** meets the growing demand for a current-awareness journal devoted to reviews, comment and the rapid interchange of biological ideas.

The first issue will include:

Reviews
Cell lineage labels in the early amphibian embryo J. M. W. SLACK; Recombinant DNA techniques in diagnostic and preventive medicine S. HODGKINSON and P. SCAMBLER; Uteroferrin: a protein in search of a function R. M. ROBERTS and F. W. BAZER; Plasma membrane-microfilament interactions in animal cells K. L. and C. A. C. CARRAWAY.

Features
A new genesis for genetics and medicine P. LEDER; The OTA Report on biotechnology: A U.K. perspective G. H. FAIRTLOUGH; The Road to Asilomar: Reminiscences of the Recombinant DNA Story, Part One DeWITT STETTEN, Jr; Software for molecular biologists. Part I M. J. BISHOP

uses to test various ideas about scientific communities, natural philosophy and scientific change.

Cantor takes a sociological approach. This is most fruitful in the treatment of the surprisingly large number of fluid theorists that he has uncovered, for they were for the most part attempting to use theories of light in Biblical interpretation and were not engaged in science, by making predictions, doing experiments or explicating optical phenomena. By Cantor's own account, they were marginal to the British scientific community at the beginning of his period of study and irrelevant by its end.

When Cantor turns to more serious scientific theories, such as the Newtonian emission theory, his sociological concepts are too narrowly conceived. For instance, he argues that no research occurred in the emission theory from 1700 to 1740, because its proponents were diverted by teaching. Besides the simple confusion of a cause and a correlation, this sort of claim could dily be tested by a comparison with the lation on the Continent during that period. Indeed, Cantor's self-imposed restriction to Britain and Ireland is a serious flaw, for a strong case can be made that the British Isles were a scientific backwater for most of the period from 1704 to 1840, so that what he has given us is actually an account of a relatively stagnant scientific community, rather than a progressive one. Thus, at the beginning of the nineteenth century, when he declares the emission theory to have been in decay in England, it was flourishing in France in the hands of Laplace, Biot and Malus.

An explanation for the initial neglect of Young's contributions — the most important and original British work in this study — provides, as Cantor recognizes, a critical test of his account. I am, however, only partly persuaded by his solution, namely, that the principle of interference was rejected because it was associated with Young's unoriginal wave theory. Cantor underestimates the quality of Young's work and depends too much on denigrating both him — Euler's "English disciple of moderate competence" — and his work, which he does not fully and clearly explain. He also introduces an artificial distinction that too sharply differentiates Young's and all earlier "vibration" theories from Fresnel's mathematical "wave" theory, whereas I believe there is a genuine continuity from Huygens through Euler and Young to Fresnel.

The most valuable feature of *Optics after Newton* is the vast quantity of primary literature described by Cantor, which can serve as a base for future work on the history of optics, not just British theories of light. □

Firsts for feminism

Morris Kline

A Convergence of Lives: Sofia Kovalevskaia, Scientist, Writer, Revolutionary.
By Ann Hibner Koblitz.
Birkhäuser: 1984. Pp.305. $19.95.

WHY should anyone be interested in a biography of someone whose name, much less her work, is known to very few people and who died nearly one hundred years ago? The chief reason for this fine biography is that Sofia Kovalevskaia was a first-class mathematician, who achieved a place for herself in a period when women were hardly recognized outside the home.

In her time, Kovalevskaia achieved high professional status; she was the first woman to be awarded a doctorate in mathematics, the first (outside Italy) to become a professor of mathematics, and the first to serve as editor of a major mathematical journal. She also made impressive contributions to literature, and engaged in social and political efforts in the cause of women's rights. All of these activities were carried on during a life span of only 41 years (1850–1891) and despite the inevitable opposition from male professors in mathematics and other fields.

Kovalevskaia had become attracted to mathematics even as a child, when she was instructed by tutors. To counter the opposition to women as students in the higher Russian academic institutions, she managed by a rather frequently used subterfuge, called fictitious marriage — legal but not sexual — to get out of the country in order to study mathematics. Most of the book is devoted to her development, to the lives of her immediate family and friends, and to her troublesome relations with her husband, who was a geologist. Later, she and her "fictitious" husband did become sexually involved; the marriage produced a daughter.

Kovalevskaia's pursuit of mathematics was her main drive in life. After leaving Russia, she became a student at the University of Heidelberg where she spent several years. There she learned of the work of Karl Theodore Weierstrass (1815–1897), one of the leading mathematicians of Europe and a professor at the University of Berlin. Though she was denied admission to the university, Weierstrass was greatly impressed with her ability and took her on as a private student. With his backing she received a doctorate in mathematics.

Fortunately, Gösta Mittag-Leffler, a liberal Swedish mathematician, then sponsored her for a professorship at the University of Stockholm, a post she took on leaving Berlin and held for many years. During these years, and even earlier, she came to know the leading mathematicians of Europe; it was through recognition in this way, and despite considerable opposition from the establishment, that she was elected to the Russian Imperial Academy of Sciences.

To those who are primarily concerned with the history of mathematics as such, this book will be a little disappointing. There is little mention of Kovalevskaia's actual work, beyond a list of her publications. But it is clear that whereas some mathematicians make brilliant creations as youths, Kovalevskaia developed slowly. In her case the educational difficulties she faced were at least partly responsible, and had she lived longer she would have surely produced much more. Equally interesting to historians of the intellectual connections in the nineteenth century are many of the remarks and details concerning the mathematicians with whom Kovalevskaia kept contact. In particular, her relationship with Weierstrass, who practically adopted her as a daughter, reveals much of that man's noble character.

Ann Hibner Koblitz quite clearly has done a great deal of research in Russia and Stockholm to write this lucid biography. The bibliography is immense and will be of great value to other scholars. Her book should also be of interest to a broad audience, as an example of what a woman could accomplish in nineteenth-century anti-feminist Russia and for the insight into the political and social climate of that period. My only quibble is the word "revolutionary" in the title. Kovalevskaia was indeed what we nowadays know as a feminist. But she was not a militant. □

First steps in spectroscopy

K. A. McLauchlan

Interpretation of NMR Spectra: An Introductory Audiovisual Programme. By J.D. Coyle, E.J. Haws, K. Miller and K. Norton.
Wiley: 1984. £199.

WILEY's new audiovisual programme comes in a striking package, a large boxed folder which contains four tape cassettes and four boxes (in which are a total of 164 coloured slides), and also 20 booklets. Each tape deals with a particular subject — the chemical shifts of protons, the spin–spin coupling of protons, use of proton spectra for structural assignment and all three of these topics applied to ^{13}C spectra — and is complemented by the slides. Run freely each tape lasts for about 40 minutes, although the package is designed to be interactive with the student so that he may stop and start the tape at will so as to suit his own pace of learning. This is best accomplished with a dedicated slide-tape machine, but an ordinary tape recorder and a slide projector can be used if necessary.

Two types of booklet are supplied, ten of each, together with a correlation chart of proton chemical shifts and a listing of proton coupling constants. The latter is inadequate, even at this level, as is the correlation chart for ^{13}C shifts which is found inconveniently on a slide. One booklet is a very simplistic introduction to NMR spectroscopy. The other is a workbook which has well-defined learning objectives, and in which the student is encouraged to write his replies to answers posed on the tapes and the slides. Answers are supplied on the succeeding slides.

The course has been put together with a great deal of care; the presentation on the tapes is clear and slides are beautifully presented. The coordination of the material between booklet, slide and tape is excellent, too — in theory; my programme did not run properly but that could a quirk of the review package. The tape cues in the operation of the slide–tape machine and the mechanism changes the slide one is looking at to correspond to what is being said, while the tape stops at pre-ordained places to allow the student to think before he goes on.

The material itself is extremely elementary, aimed primarily at trainee technicians but also perhaps at students at the school–university interface or at first-year undergraduates in organic chemistry. In its determination to be straightforward — it is after all an introductory course — it contains slight inexactitudes and half-truths which might worry the better student. Worse, however, is that the package represents the state of knowledge of the subject as it was about 20 years ago. At this level it forms a very basic introduction to the subject which might well build confidence in the student, but if one is going further the background needed would have to be more thorough — Fourier transformation, double resonance, 2D spectroscopy and the various pulse sequences all lie beyond the scope of the Wiley course.

It is initially attractive to think of replacing myself in all those tutorials each week with a magic box, but what are its disadvantages? The publisher extols the virtue of being able to hear the commentary and see the slides at the same time, rather than have your eye skip rapidly from text to diagrams as in a book — fine, provided everyone has a slide-tape machine in his own room! More importantly, this form of teaching seems to be based upon the precept that a student learns in the classroom, but one of the aims of education should be to free him from this restriction. A student should be inquisitive, but how is this virtue encouraged by sitting before a machine which cannot answer questions and which has been programmed by someone else's narrow concept of what should be taught?

Nuclear magnetic resonance is, at best, a subtle, exciting but challenging subject which repays real effort in learning. I am afraid that there is no substitute for a live tutor willing and able to discuss its depths and its applications, to maintain this interest and sense of involvement with developing science on many frontiers. For myself, the Wiley package offers no respite from tutorials, but teachers of the subject at technical colleges may well find it a helpful adjunct to their lectures. □

K.A. McLauchlan is a Lecturer in the Physical Chemistry Laboratory, University of Oxford.

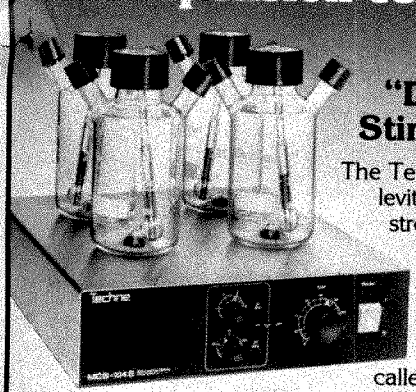
Tigers and calotypes

Brian Coe

Beyond Vision. By Jon Darius.
Oxford University Press: 1984. Pp.224. £15.

IN RECENT years there has been something of a glut of books of historic photographs. As a rule, either the photographs have been chosen to illustrate the history and development of the photographic process, or, based upon the dubious proposition that photography is Art, pictures have been selected for their supposed aesthetic merits. Very few photographs have been presented for their scientific importance — yet, as Dr Darius makes clear in his introductory essay, from its inception photography has been employed to great purpose by scientists. The collection of 100 historic scientific photographs, well reproduced in *Beyond Vision*, is therefore all the more welcome.

Dr Darius has applied very rigid criteria in selecting the photographs, the most important being that each should be unique and should show only what cannot be seen by the unaided human eye. Since the book is presumably intended for a lay readership, it might be argued that slightly less rigid demarcations might have provided greater variety; well over 60 per cent of the illustrations are of astronomical subjects or specialized aspects of physics. In any case, some of the subjects shown appear to fall outside the limits set. The record of the Tasmanian tiger, now extinct, is still no more than a fascinating document of a subject visible to the unaided eye. And the rather pretty colour photograph of the H-bomb test at Eniwetok is no more than a plain record; why were the extraordinary sequence photographs of the first microseconds of the fireball made by Dr Edgerton's highspeed camera not chosen?



The inclusion of the contentious Skaife "instantaneous" photograph of a mortar shell in flight is also a little odd. The picture has clearly been retouched, and even if it is authentic its purpose was not scientific but promotional. There are questionable omissions, too. For instance, no example of the forensic use of ultra-violet and infra-red photography is included, and there is not a single scanning electron micrograph of any sort, despite the exceedingly wide range of applications in science and industry. To be fair, in reducing the entire output of 140 years of scientific photography to 100 examples, the author could not expect to please everyone.

The introductory essay is lucid and informative but is marred by several errors. The skeleton outline of photographic processes is misleading; it makes no mention of the key fact that the calotype process made paper negatives which could be printed. To use the description "coated with emulsion" to cover such diverse processes as the Daguerreotype (a silver surface sensitized by iodine vapour), the calotype (paper impregnated with silver salts), the collodion process (a glass plate coated with halide-containing collodion and sensitized in silver nitrate) and the dryplate process (a suspension of silver salts in melted gelatin coated onto glass or paper) is carrying simplification too far. Talbot's early photomicrographs, *c.* 1837, were not calotypes, but were made by his earlier "photogenic drawing" process.

Seen against Dr Darius's achievement in bringing these photographs together, these are minor criticisms. Overall, the book is a most valuable contribution to the literature on the history of photography. We must hope that it will be sufficiently successful to be followed by a second selection revealing more of the wonders of scientific photography. □

Brian Coe is Curator of the Kodak Museum at Harrow, Middlesex.

Multiply cell yield in your suspension cell cultures

with Techne "Double Helix" Stirring Systems

The Techne Stirring System levitates cells in a steady stream upwards around the axis of the flask and causes them to descend outwards to the center of the bottom surface. It is called the Thomson flow pattern. We call it the "Techne Double Helix" since the motion consists of ascending and descending helices. Our system is unique* and unobtainable in conventional spinner flasks. This gentle circulation of the medium optimizes cell growth and is excellent for difficult-to-grow cells, hybridomas and monoclonal antibodies.

For full details, call or write for Catalog 203.

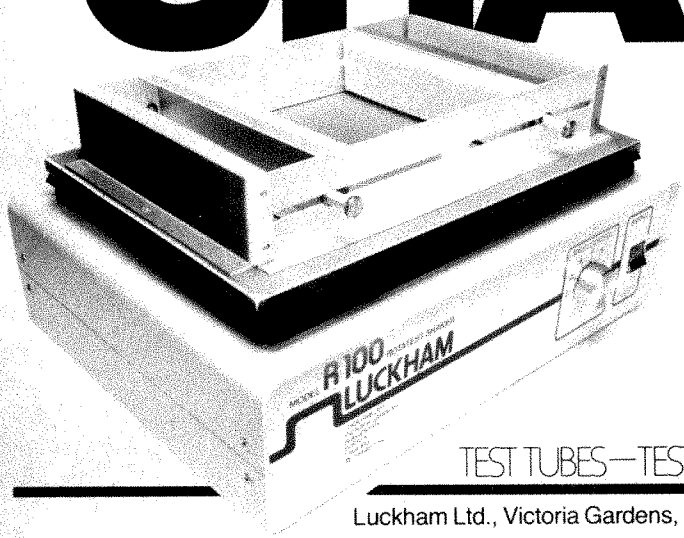
For researchers in all areas of the plant sciences, **Plant Cell Reports** presents original, short communications dealing with all aspects of plant cell and plant cell culture research. These articles cover fundamental and applied research results in

- physiology
- biochemistry
- molecular biology
- cytology
- genetics and genetic engineering
- phytopathology
- morphogenesis, including plant regeneration from protoplasts, cells, tissues, and organs

Contributions are published on average within six weeks of receipt of the final version. This rapid publication enables industrial and academic researchers to stay abreast of developments as they happen by subscribing to **Plant Cell Reports.**

Indexed in Current Contents/Agriculture, Biology and Environmental Sciences.



Subscription Information: 1984, Vol. 3 (6 issues): DM 196,- (approx. US $ 75.00), plus carriage charges.

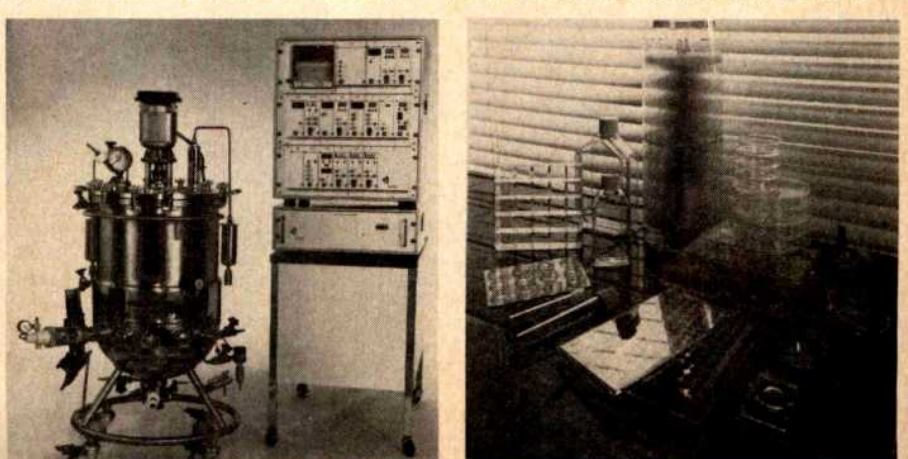
New for tissue culture

The eleven items here cover recently announced products of use in the tissue culture laboratory

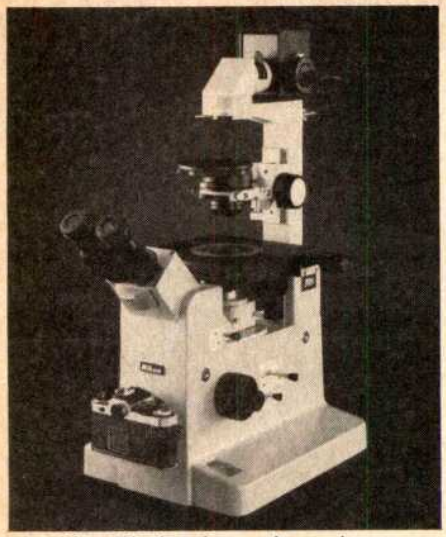
● A new range of culture dishes is now available from International Bio-Technologies (IBT) Ltd. The dishes are coated with a naturally produced extracellular matrix (ECM), a basement membrane-like substratum which promotes cell attachment, proliferation and differentiation. The ECM is secreted by endothelial cells cultured on conventional tissue culture plastic. The cells are then removed, leaving the underlying ECM intact and firmly attached to the surface of the dish. The composition and supramolecular arrangement of the ECM is similar to basement membranes occurring *in vivo*. Cells placed in contact with ECM attach rapidly, exhibit high plating and cloning efficiences, proliferate rapidly, reach a h saturation density and have much ver requirements for serum and added growth factors than cells in conventional dishes. They also respond better to physiologically occurring hormones and express differentiated functions. These effects cannot be obtained by cell plating on isolated fibronectin, laminin or each of the collagen types and on reconstituted matrices. Among the cell types showing a favourable response to ECM are normal and carcinomatous human epithelial cells derived from surgical biopsies, human amniotic fluid cells, bovine granulosa, adrenal cortex and endothelial cells, rat pituitary, oligodendrocytes and dorsal root ganglia cells. The coating is available on any size of tissue culure dish, T-flasks, multiwell plates and coverslips.
Circle No. 100 on Reader Service Card.

● The culture of hybridomas and diploid human cells has become increasingly important and this has led LSL Biolafitte of Princeton, New Jersey, to design a range of vessels specifically suited to this purpose. LSL Biolafitte offers eight vessels with working volumes from one litre to 330 litres. Each vessel has optimized geometry with a working height to diameter ratio of 1:1 and hemispherically shaped base. An effective low speed, low shear agitation system is incorporated into each vessel to gently agitate the cells. Harvesting is achieved by a conveniently located valve which has two positions allowing total drainage or liquid removal only. Other system design features are included, or are available as optional accessories, to ensure strict containment in processes where this is an important factor.
Circle No. 101 on Reader Service Card.

These notes are based on information provided by the manufacturers. For further details circle the appropriate numbers on the Reader Service Card bound inside the journal.

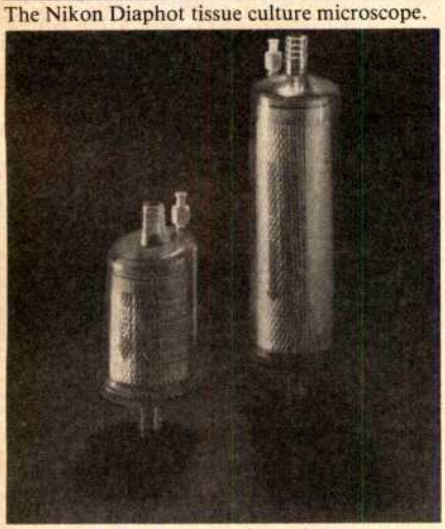


Adult rat oligodendrocytes maintained on conventional plastic (left) and on plastic coated with IBT's extracellular matrix preparation.



● The Sterilin range of tissue culture plastics includes dishes, tubes, flasks, plates and bulk vessels designed to ensure efficient attachment and growth of cell monolayers. All equipment is manufactured from non-toxic polystyrene, providing a high standard of finish and good optical properties for microscopy. Every batch is tested for sterility and the ability to support cell growth. Petri dishes are available in a wide range of sizes and types — the 50mm and 60mm dishes can be supplied with single or triple vents and a multi-well dish is also available. Sterilin test tubes come in two sizes: the 13ml tube is fitted with a leak-proof screw cap, and the 5ml tube has a two-position cap for gas exchange. For research and clinical studies involving human and animal cells, two sizes of tissue culture flask are available. Graduated in mls, the wide necks (canted in the 25cm^2 size) allow easy pipette access and non-toxic leakproof screw caps are fitted for safety. A stacking rim is provided for extra stability. All flasks are individually pressure-tested to eliminate the possibility of leakage through the welded seams.
Circle No. 102 on Reader Service Card.

● Sera-Lab fetal calf sera are now available in graded batches to select those which will support the rat and mouse myelomas used to make cell hybrids. Each batch of serum is routinely tested for the ability to support the growth of 11 cell lines, so at no extra cost the customer can request a serum to suit a particular need.
Circle No. 103 on Reader Service Card.



● A kit for preparing serum-free media has been announced by Gibco. The Select-a-Factor kit contains 1 ml sample sizes of the more commonly-required factors and technical information on how to grow cells in a serum-free environment. The technical information describes four experiments that explain the preparation of serum-free media. The kit includes 1 litre of powdered medium (Dulbecco's minimum essential medium: nutrient mixture F-12 with 15-mM HEPES), trypsin inhibitor and 14 ready-to-use factors (EGF, FGF, fibronectin, poly-D-lysine, vitamins C and E, insulin, transferrin, hydrocortisone, progesterone, selenium, putrescine, trace element mix, and T_3). The factors are also available individually for the preparation of subsequent media.
Circle No. 104 on Reader Service Card.

One of the LSL Biolafitte culture vessels (left) and the Sterilin range of tissue culture plastics.

The Nikon Diaphot tissue culture microscope.

Disposable filter capsules from Gelman.

● The range of accessories available for the Nikon-Diaphot inverted tissue culture microscope now includes systems for time-lapse cine photomicrography or closed circuit television that can be fitted without disturbing the camera mounted on the front. Motor driven computerized stepping stages can be fitted to the Diaphot for image analysis work, and for environmental control, the Nikon constant temperature incubator can provide warm air at 37°C. An override allows variation in temperature of plus or minus 4°C.

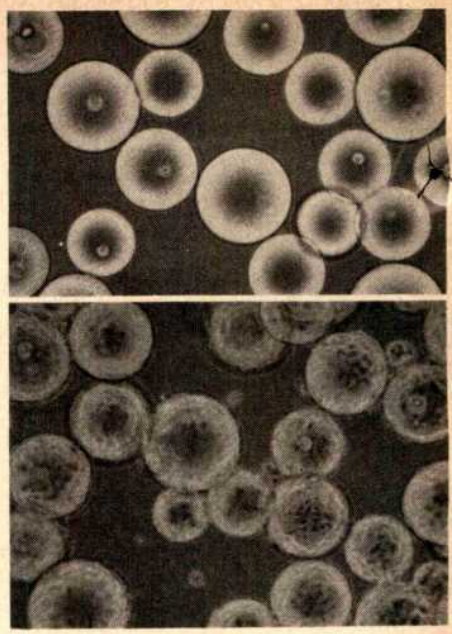
Liposomes



A **new** laboratory instrument (LIPOPREP®-GD-1) is available for the **reproducible** preparation of extremely homogeneous, unilamellar liposomes of controllable size. The instrument permits the **simultaneous use of five different lipid mixtures** and provides extensive versatility. Applications range from membrane reconstitution, remodelling of cellular functions, liposome drug delivery systems, microanalysis of drugs and metabolites, to antibody targeting, clinical diagnostic assays, and genetic engineering.
For details write to:
DIANORM-Geräte, P.O. Box 126, D-8 München 65, FRG.

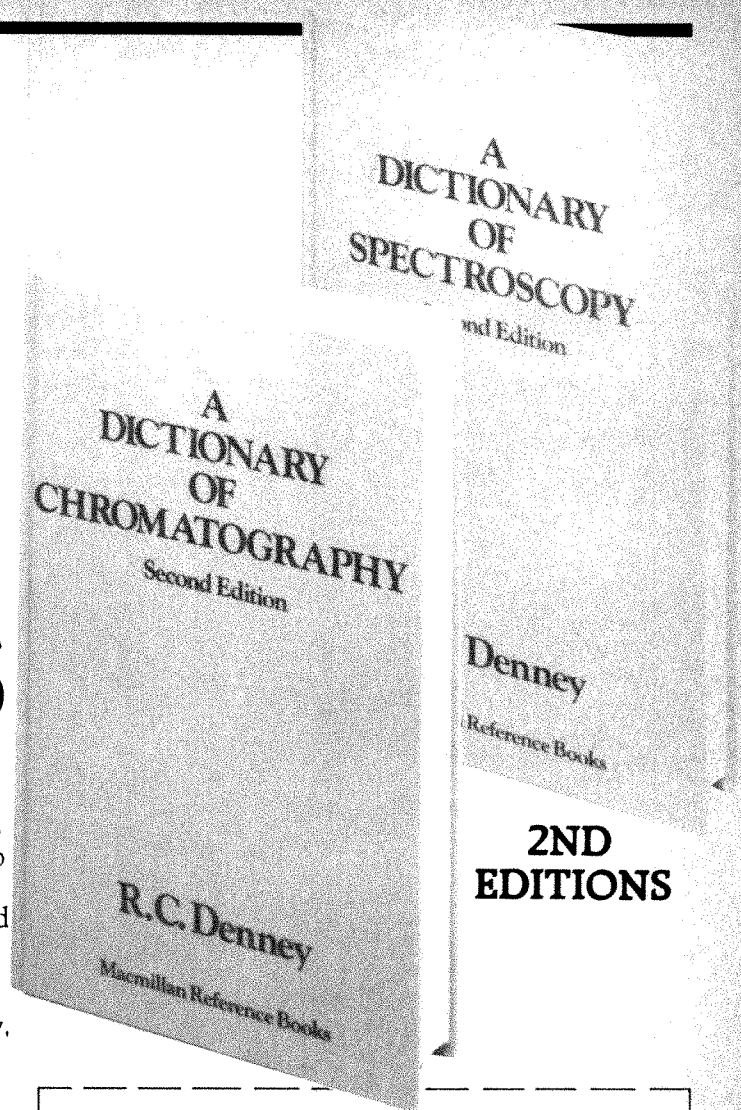
Circle No.22 on Reader Service Card.

● Gelibead, a gelatin microcarrier developed by KC Biological, solves two of the major problems associated with microcarrier culture. First, enzymatic removal of viable cells from the microcarrier is possible and second, eluted cells can be readily removed from the spent microcarriers. Gelibead microcarriers permit highly efficient cell harvesting because they completely dissolve in a mixture of trypsin, dispase and EDTA. Exposing Gelibeads for about 20 minutes to this mixture results in complete dissolution of themicrocarriers with very high cell recoveries. Gelibeads can be attached to a wide range of cell types, provides high density culture (about 3,800 cm^2 per gram dry weight) and gives high cell yields.
Circle No. 106 on Reader Service Card.

● In the new Luckham RMV tissue culture roller apparatus the rollers rotate at a set speed with the minimum of variation, resulting in steady even culture growth. All rollers are driven, they are covered in rubber and support the bottle along its whole length. The unit is available in two speed ranges, 2–10.5 revolutions per hour or 40–180 per hour (other speed ranges are available to special order). There is an analogue speed meter so that experimental conditions can be precisely reproduced. Luckham has also just introduced the TC 1000, a drum roller designed for the rotation of 16-mm diameter tubes. The unit has a variable speed between 0.5 and 60 r.p.m. Speed is electronically controlled, and read out via an analogue meter. Luckham manufactures a range of racks designed for tissue culture work, with a variable angle between 0 and 5 degrees.
Circle No. 107 on Reader Service Card.

● Gelman's new "Culture Capsule" and "Maxi Culture Capsule" are disposable, ready-to-use capsule filtration devices for sterilizing large volumes of tissue culture media. These presterilized capsules incorporate two layers of 0.2 μm low-protein-binding HT Tuffryn membrane, and are designed and certified to assure their integrity for tissue culture media sterilization. Designed for use with positive pressure filtration, the Culture Capsule and Maxi Culture Capsule are suitable for in-line applications using a pressure vessel or peristaltic pump. For sterilization of culture media containing serum, either capsule may be used as the final sterilizing unit in conjunction with prefilters. Disposable filters minimize set-up time and risk of cross-contamination. The Culture Capsule (product no. 12140) provides 500 cm^2 typical filter area, suitable for sterilization of up to 10 litres of solution. The Maxi Culture Capsule (no. 12141) offers 1,290 cm^2 typical filter area, and is ideal for larger volume applications of up to 20 litres. Both capsules are available from the following laboratory supply dealers: American Scientific Products, Fisher Scientific, VWR Scientific and Curtin Matheson Scientific.
Circle No. 108 on Reader Service Card.

The Gelibead microcarrier without cells (top) and with attached MDCK cells.



Luckham's new tissue culture roller.

● A new product from Hana Biologics is intended to reduce the requirement for serum in mammalian cell culture. SerXtend is a combination of growth factors which when added to fetal bovine or other sera will allow for a 50% or greater reduction in the concentration of serum used in cell culture. It is a non-serum based product, formulated and certified by biological activity to allow for lot-to-lot consistency.
Circle No. 109 on Reader Service Card.

● The new Microtec Swift tissue culture microscope is an inverted microscope which can be fitted with bright field or phase contrast objectives designed to work through the chambers used in tissue culture. Illumination is provided by a 20 watt halogen source and, with the standard condenser, chambers up to 45mm thick can be used. An extra long working distance condenser system, with a working distance of 60mm, is available for use with thicker chambers. A camera port is a standard feature enabling a 35mm camera to be plugged into the side of the microscope. The coaxial coarse and fine focusing mechanism operates entirely on the objectives, so that viewing head, camera and specimen stage are in a fixed position.
Circle No. 110 on Reader Service Card.

Essential for all Chemists

2ND EDITIONS

When you work or study in a field which is changing as fast as spectroscopy and chromatography it's not easy to keep up-to-date with all the new developments. New instruments are constantly appearing on the market and new techniques are being evolved in one of the fastest growth areas of modern science.

These dictionaries of chromatography and spectroscopy, already highly acclaimed in their previous edition, will enable you to:

* **broaden your knowledge of new products and instruments**
* **obtain rapid explanations of new terms and techniques**
* **relate your own speciality to other areas**
* **check symbols and equations quickly and efficiently**

A Dictionary of Spectroscopy covers such areas as atomic spectroscopy, emission spectroscopy, electron spin resonance, infrared and ultraviolet spectroscopy, nuclear magnetic resonance, photoelectron spectroscopy, photo luminescence, mass spectroscopy and Raman spectroscopy.

A Dictionary of Chromatography covers gas chromatography, gas liquid and gas solid chromatography, liquid chromatography, paper chromatography and thin layer chromatography.

Both dictionaries are clearly illustrated with over 50 drawings and diagrams and give numerous references for further specialised reading.

Animals in scientific research: An effective substitute for man?

Edited by Professor Paul Turner,
Head of the Dept. of Clinical Pharmacology,
St. Bartholomew's Hospital.

Based on a conference held by the Humane Research Trust in April 1982.

April 1983: £35: 228pp: ISBN 0 333 33628 3

Contents

Preface; A more scientific approach to the safety evaluation of chemicals – *Dennis V. Parke*; The use of short term tests to detect the carcinogenic and mutagenic potential of environmental chemicals – *James M. Parry*; The design and use of *in vitro* toxicity tests – *James W. Bridges, Diane J. Benford and Susan A. Hubbard*; A review of the value of isolated hepatocyte systems in xenobiotic metabolism and toxicity studies – *Jeffrey R. Fry*; Legislating against cruelty – *R.S. Vine*; Isolated human cellular models in clinical pharmacological studies – *Paul Turner*; The role of mathematical models in biomedical research – *Ewart R. Carson*; Uses and limitations of tissue culture in drug testing – *Mary Dawson*; *In vitro* systems in the study of osteoarthritis – *Helen Muir and J.D Sandy*; Biocrystallography – *J.E. Malcolm*; Comparative medicine – *R.N. T-W-Fiennes*; Testing for delayed effects on development and differentiations: Some open questions – *R.M. Clayton, A. Zehir and K. Sedowfia*; Monitoring human and animal intra-uterine development with non-invasive methods and perfecting *in-vitro* placental perfusion techniques for toxicologic and teratologic experiments – *Maurice Panigel.*

UNIVERSITY OF LIVERPOOL

DEPARTMENT OF SURGERY

TECHNICIAN GRADE 7

to organise the provision of a technical service in research laboratories which undertake a wide variety of biochemical, histological and immunological work. Other duties include assistance with organising examinations and responsibility for budgeting research grants.

Candidates must possess HNC or appropriate equivalent as minimum qualification plus ten years relevant experience including staff supervision.

Salary within range £8,385-£9,418 per annum (under review).

Applications forms may be obtained from The Registrar, The University, PO Box 147, Liverpool, L69 3BX. Quote ref RV/519N.

(2075)A

UNIVERSITY COLLEGE LONDON

DEPARTMENT OF ANATOMY AND EMBRYOLOGY

LECTURESHIP

Applications invited for a LECTURESHIP. No particular field is sought, but applicants are expected to have a strong commitment to original research. The Department has broad interests and excellent facilities. The position offered is in lieu of a Wellcome Trust Senior Lectureship, so "the tenure of the award (post) is for no less than an initial five years, followed by possibly a further one or more periods each of three years".

Applications, together with full cv (including publications list) and the names of three referees, should be sent to: Assistant Secretary (Personnel), University College London, Gower Street, London WC1E 6BT. (2128)A

UNIVERSITY OF CAMBRIDGE

DEPARTMENT OF PHYSICS

PHYSICIST/CHEMIST

Applications are invited for a pos doctoral Physicist or Chemist t work for 18 months in the firs instance on the electronic propertie of conducting polymers and organi semiconductors. The project covers wide range of physical measure ments, including optical and tran port properties, and will involve th preparation, characterisation an chemical or electrochemical dopin of these materials.

Salary in the range £6,745 to £9,42 pa.

Applications to Mr J Deakin Secretary of the Department Physics, Cavendish Laborator Madingley Road, Cambridge CB 0HE, quoting ref RF. Closing date June. (2078)A

Clinical Research Associate

Greenford, Middx.

Glaxo Laboratories Limited is a leading British pharmaceutical company responsible for the promotion of products of original research developed and manufactured in the UK. We are now seeking to recruit an experienced Clinical Research Associate to join the Company's Medical Services Department.

You will be required to arrange Clinical Trials and bring them to a satisfactory conclusion by ensuring that data is collected and handled efficiently once received. You will be involved in the preparation of protocols and the administration connected with the study and you will be expected to meet Clinical Trialists on a regular and frequent basis.

In addition to a degree in pharmacy or a suitable science, you should have experience in the field of gastroenterology, possess a dynamic and friendly personality and be able to communicate effectively, both verbally and in writing.

The attractive conditions of employment include non-contributory pension scheme, four weeks' and two days' holiday, a subsidised cafeteria, a Group Bonus Scheme and excellent sports and social facilities.

Please telephone for an application form to: Mr. M. E. Bates, Senior Personnel Officer, Glaxo Laboratories Ltd., Horsenden House, Oldfield Lane North, Greenford, Middx. on 01-422 3434, ext. 2837 quoting ref. MEB/736.

Glaxo Laboratories Ltd

Molecular Biologists

A challenging career opportunity in genetic engineering.

ICI Australia Operations Pty. Ltd. Central Research Laboratories in Melbourne, are equipped with a comprehensive range of biological and chemical research facilities. The laboratories have a staff of 160, including more than 100 graduates. The Company has been a leader in research and development in Australia for over 20 years and has strong contacts with other research institutions throughout Australia, including those involved in biotechnology.

We are seeking two Molecular Biologists to participate in the establishment of a strong new team in the field of genetic engineering. The immediate aim of the team is the expression of eukaryote genes in bacteria and there will be a long-term commitment to the genetic manipulation of micro-organisms to meet a range of company targets.

Consideration will be given to applicants either completing a Ph.D. in recombinant DNA work or with post-doctoral experience in a laboratory of international standing in the same field.

The salary offered initially will depend on qualifications and experience and is subject to annual review. Benefits include contributory superannuation scheme and supplementary non-contributory medical benefits scheme.

ICI is an equal opportunity employer.

Personal details and a full account of research experience, techniques and publications with the names of two or more referees, should be sent to:

Personnel Manager,

ICI Australia Limited

G.P.O. Box 4311,
Melbourne, Vic. 3001, Australia.

The ICI Roundel is a Trademark (W1006)A

CSIRO

RESEARCH SCIENTIST/ SENIOR RESEARCH SCIENTIST

A$25,342 – A$37,274

Division of Entomology, Canberra ACT

Field: Application of Molecular Biology in Entomology.

General: CSIRO conducts scientific and technological research in laboratories located throughout Australia and employs about 7,500 staff, of whom some 2,900 are professional scientists. The Organization's research activities are grouped into five Institutes: Animal and Food Sciences, Biological Resources, Energy and Earth Resources, Industrial Technology and Physical Sciences. The CSIRO Division of Entomology is a member of the Institute of Biological Resources.

The Division of Entomology conducts research on entomological problems of both basic and applied importance. It recently initiated a molecular program aimed at investigating how genetic information is stored in the insect genome and used during development. Such knowledge should assist in the identification of novel methods of pest control. The Division has a well equipped molecular biology laboratory and maintains active research programs in insect biochemistry, physiology, behaviour and genetics. The Australian sheep blowfly *Lucilia cuprina* and *Drosophila melanogaster* are major experimental organisms used in these programs.

Duties: The successful applicant will combine a knowledge of genetics and molecular biology to elucidate the molecular mechanisms determined by genes responsible for insect development and pattern formation. An interaction is envisaged with other staff currently using recombinant DNA techniques and insect transformation to study chromosome structure and gene function.

Qualifications: Applicants should have a Ph.D. or equivalent in a relevant field, preferably with research experience in insect biochemistry, physiology and genetics, and must be competent in analyses of DNA and RNA, molecular cloning and nucleic acid sequencing.

Tenure: Indefinite. Australian Government superannuation benefits available.

Applications: Stating full personal and professional details, the names of at least two referees, and quoting reference no A0605 should be forwarded to:

The Chief
CSIRO Division of Entomology
CANBERRA CITY ACT 2601
AUSTRALIA
by June 22, 1984. (W996)A

CHAIR IN ORGANIC CHEMISTRY

Applications are invited, from candidates of either sex, for appointment to a Chair in Organic Chemistry in the Department of Chemistry.

The person appointed will be ready to sustain and develop the distinctive industrial interests of the Department. His/her research activities may be in any branch of Organic Chemistry, but preference will be given to candidates with an interest in synthetic organic chemistry in its widest context. A good record of, and potential for, attracting industrial support for the research will be a distinct advantage.

Salary will be in the Professorial range, minimum currently £17,275 p.a., but under review.

Informal enquiries may be made of Professor J O Williams (Chemistry Department) or of The Registrar.

Requests for application forms and further particulars, quoting reference CH/70/A1, should be addressed to The Registrar, Room B9 UMIST, PO Box 88, Manchester M60 1QD. Completed applications should be returned as soon as possible.

(2104)A

UMIST

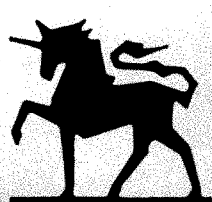
The University of Manchester Institute of Science and Technology

Head of Pharmacology

KENT

The Wellcome Foundation Limited is a major group of pharmaceutical and chemical companies with headquarters in the UK and a turnover close to £700m.

This is a key senior appointment reporting to the Director of Therapeutic Research Division. The department is active on a wide variety of forward-looking research projects and comprises some 60 personnel – including scientists, technicians and clerical/secretarial staff.



The prime responsibility of the position will be to direct, manage and co-ordinate the department's activities and resources to meet the overall research objectives within defined cost, quality and time parameters. There is also a requirement to co-ordinate "the development of the science" and ensure that a consistency of high quality of scientific and technical performance is sustained.

Candidates must be able to demonstrate a substantial scientific and managerial track record in a relevant field and have the maturity to promote and develop scientific excellence through personal leadership and motivation. As a senior scientist, the successful candidate must also be capable of contributing to the general debate on scientific research methodology objectives and maintaining a contemporary scientific perspective in this important area of research.

The salary and benefits package will reflect the importance of the position and includes a company car and generous assistance with relocation expenses.

Please write with full c.v. to
Alan Murdoch, Personnel Officer,
The Wellcome Research Laboratories,
Langley Court, Beckenham, Kent BR3 3BS, England.

IRI

Inveresk Research International

MAJOR OPPORTUNITIES IN BIOTECHNOLOGY

Location — Scotland

Inveresk Research International Limited has substantial development in Biotechnology underway and is already a leading force in the contract research area. Activities focus on monoclonal antibodies for diagnosis and therapy and in genetic engineering. Our laboratories are modern and well equipped and we are now moving into a phase of further expansion as a result of which the following vacancies have now become available:-

HEAD OF IMMUNOLOGY

Candidates for this appointment should have proven management capabilities as the person appointed will be responsible for our human monoclonal antibody research, which will involve running an already experienced team. The desired qualifications are a PhD with at least several years' industrial experience.

At least initially, this post will be located in our Glasgow laboratories in George Street. (Reference Number: 3502).

CONTRACT BIOTECHNOLOGY MARKETING MANAGER

Candidates for this appointment must have an ability to broaden our client base in the Biotechnology area. An aptitude in proposal writing and/or knowledge of licensing of intellectual property would be added advantages. The required academic qualifications are at least an Honours Degree.

This post will be based at our Biotechnology laboratories in Musselburgh. (Reference Number: 2590).

Applicants for either of the above posts must have practical experience in appropriate fields and must have the necessary drive and initiative to operate successfully in a commercial environment. Salary in both cases will be according to qualifications and relevant experience.

In addition, the Company offers modern staff benefit schemes, including free BUPA membership, and a modern working environment. Relocation expenses may also be provided, where appropriate.

A full c.v., should be submitted in confidence to the Personnel Department, Inveresk Research International Limited, Inveresk Gate, Musselburgh EH21 7UB, quoting the appropriate reference number. (2107)A

UNIVERSITY OF LEICESTER
Leicester Biocentre

POSTDOCTORAL RESEARCH ASSOCIATE
Yeast Molecular Biology

Applications are invited for a postdoctoral research position, funded by a major UK Food and Drink company, to undertake research aimed at the improvement of existing yeast strains for commercial applications.

The project will involve the use of genetical, biochemical and recombinant DNA methods and Applicants should hold a PhD in a relevant subject. The contract is for a period of 3 years and appointment will be made within the Grade 1A salary scale (ie £7,190 — £11,615).

Applications, with full curriculum vitae should be sent to the Secretary, Leicester Biocentre, University of Leicester, Medical Sciences Building, Leicester LE1 7RH. (2105)A

VIRGINIA COMMONWEALTH UNIVERSITY
MEDICAL COLLEGE OF VIRGINIA

DEPARTMENT OF HUMAN GENETICS

HUMAN MOLECULAR GENETICIST

The Department of Human Genetics of the Medical College of Virginia is seeking applications for an assistant professor position. Candidates must have a doctoral degree, at least two years postdoctoral experience and a strong background in Human Genetics. The successful applicant will be expected to establish an independent research program and to participate in graduate studies.

To apply, send vitae and three letters of reference to Dr W E Nance, Box 33, MCV Station, Richmond, VA 23298.

Equal Opportunity/Affirmative Action Employer. (NW539)A

THE UNIVERSITY OF WESTERN AUSTRALIA
Perth

CHAIR IN MICROBIOLOGY

Applications are invited for appointment to the Chair in Microbiology which became vacant at the end of 1983 on the retirement of Professor N F Stanley. A newly established Chair in Clinical Microbiology is currently under advertisement.

The appointee to this Chair will be expected to provide a high level of academic leadership and to play a major role in teaching and research and in the administration of the Department of Microbiology. The appointee will also be expected to be from time to time Head of Department. The Department is located in a modern, well equipped building at the Queen Elizabeth II Medical Centre and is responsible for the teaching of Microbiology to science, medical and dental students. The research sections of the Department comprise functional units in bacteriology and genetics, virology and epidemiology, immunology, environmental microbiology and clinical microbiology.

Candidates should have an outstanding record of research in microbiology. Although applications will be welcome from scholars in any are of microbiology, preference may be given to candidates with a strong background in virology and research interests in molecular aspects of the discipline, or in molecular biology with research interests in recombinant DNA technology.

The current salary for a Professor is $A51006 per annum, plus a clinical loading of $A4566 per annum for a medically qualified candidate. Benefits include superannuation, fares to Perth for appointee and dependent family, removal allowance, study leave and long service leave and eligibility for interstate travel grants and housing loan scheme.

Prospective applicants should write to the Staffing Officer, the University of Western Australia, or to the Secretary General, Association of Commonwealth Universities, (Appts), 36 Gordon Square, London WC1H 0PF, for further particulars before submitting applications.

Applications in duplicate stating full personal particulars, qualifications, experience and the names and addresses of three referees should reach the Staffing Officer, University of Western Australia, Nedlands, Western Australia, 6009 by 27 July 1984. (W1012)

POSTDOCTORAL POSITION

available for individual to carry out in vitro mutagenesis of cloned, selectable mammalian genes and to characterize their expression after transfection into cultured cells. Molecular genetic experience desirable. Send CV and names of 3 references to Dr Peter J Stambrook, Department of Anatomy and Cell Biology, University of Cincinnati Medical Center, Cincinnati, OH 45267-0521. (NW540)A

THE UNIVERSITY OF WESTERN AUSTRALIA
Perth

CHAIR IN CLINICAL MICROBIOLOGY

Applications are invited for appointment to the newly established Chair in Clinical Microbiology. This position is one of two Chairs in the Department of Microbiology, the other being also vacant with the retirement of Professor N F Stanley.

The Department of Microbiology is located in a modern, well equipped building at the Queen Elizabeth II Medical Centre, which includes the Medical School, Sir Charles Gairdner Hospital and State Health Laboratory Services. The appointee will be expected to play a major role in teaching and research and in the administration of the Department, to undertake and co-ordinate medical student teaching and postgraduate training in microbiology and to provide leadership and expert clinical advice on microbiology and infectious diseases to hospital clinical staff. The appointee will also be expected to direct and administer the Combined Clinical Microbiology Laboratory Service (which provides routine microbiology services to Sir Charles Gairdner Hospital and other public hospitals in Western Australia) and the associated specialist laboratories concerned with clinical and public health work in a combined microbiology service to hospitals and the public health authority.

The Department of Microbiology is responsible for teaching medical, dental and science students. The research sections of the Department comprise functional units in bacteriology and genetics, virology and epidemiology, immunology, environmental microbiology and clinical microbiology.

Candidates should hold a medical degree registerable in Western Australia, together with postgraduate qualifications appropriate for appointment at senior consultancy status. Candidates must also have extensive experience in clinical microbiology and knowledge of and expertise in diagnostic laboratory procedures. Beds will be available for a suitable appointee.

The current salary for a Professor is $A51006 per annum, plus a clinical loading of $A9120 per annum. Benefits include superannuation, fares to Perth for appointee and dependent family, removal allowance, study leave and long service leave and eligibility for interstate travel grants and housing loan scheme. Limited rights of private practice available.

Prospective applicants should write to the Staffing Officer, the University of Western Australia, or to the Secretary General, Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF, for further particulars before submitting applications.

Applications, in duplicate, stating full personal particulars, qualifications, experience and the names and addresses of three referees should reach the Staffing Officer, University of Western Australia, Nedlands, Western Australia, 6009, by 27 July 1984. (W1011)A

University College of Swansea

Wellcome Lectureship in Magnetism Applied to Medicine

Applications are invited from candidates under 35, who are not holders of a tenured University post, for a Wellcome Lectureship in the Department of Physics. The Lecturer will be expected to work closely with the Swansea In vivo Analysis Research Group (SIVARG) which is a collaborative group involving the Department of Medical Physics at Singleton Hospital and Medical Consultants of the West Glamorgan Health Authority carrying out research on in vivo body element analysis.

The appointment, which will date from October 1, 1984, will be for three years in the first instance with the possibility of renewal for a further two years, subject to satisfactory review. The salary will be on the scale £7190-£14125 per annum, the commencing salary depending upon age.

Informal enquiries may be made to Professor J. Dutton, Department of Physics, but further particulars and application forms (2 copies) must be obtained from the Personnel Office, University College of Swansea, Singleton Park, Swansea, SA2 8PP, to which office they should be returned by June 13, 1984.

(2109)A

Monsanto, a large organization with European Headquarters in Brussels and research facilities in pleasant surroundings at Louvain-La-Neuve, 30 km south of Brussels, is expanding its agriculture research programs. The Biological Evaluation section intends to make new appointments for (m/f)

Scientists

with the ability to carry out and direct applied research projects. These projects will be related to the discovery and development of plant growth regulators and fungicides for use in major arable crops.

Applicants should have a PhD in agronomy, plant pathology or related plant sciences. A strong background in plant/crop physiology, and some experience of field experimentation, would be advantageous.

Candidates should apply, enclosing a full curriculum vitae, to Personnel Department, Monsanto Technical Center, rue Laid Burniat, B-1348 Louvain-La-Neuve, Belgium.

Monsanto

(W995)A

TRUDEAU INSTITUTE

A Postdoctoral research position in infectious disease

is currently available to study interactions between several intracellular microbial pathogens and the cellular defenses in both normal and immunosuppressed animals. Current research is directed towards understanding cellular interactions responsible for the modulation of delayed-type hypersensitivity and acquired antimicrobial resistance during the development of chronic systemic disease in inbred mice. Candidates should have a strong background in infection-immunity or in immunology.

The Trudeau Institute is a private, not-for-profit basic medical research institution situated on the shores of Lower Saranac Lake, about a mile from the village of Saranac Lake and 10 miles from Lake Placid, NY. On-campus housing is available. Salary is at appropriate NIH levels.

Send curriculum vitae and names of three references to: Dr Frank M. Collins, Trudeau Institute, P.O. Box 59 Saranac Lake, N.Y. 12983. An Equal Opportunity Employer.

(NW525)A

The Queen's University of Belfast

GRADUATE/ POST-DOCTORAL RESEARCH ASSISTANT Molecular Biology

Department of Biochemistry

This post, supported by the Multiple Sclerosis Society, is tenable in the Biochemistry Department from 1st October, 1984 for one year. The appointee should preferably have interests in molecular virology and some experience in recombinant DNA methods as applied to the study of multiple sclerosis. Candidates should preferably hold or expect to receive a good honours degree in a relevant discipline. A higher degree with research experience in recombinant DNA methodology while not essential would be an advantage.

The appointee will be made within the salary range: £6,312-£8,532 per annum, placing depending on qualifications and age.

Applicants should send a full curriculum vitae including the names and addresses of two referees to the Personnel Officer, The Queen's University of Belfast, Northern Ireland, BT7 1NN. Closing date: 5th June, 1984. (Please quote Ref. 84/N).

(2118)A

Agricultural and Food Research Council FOOD RESEARCH INSTITUTE Process Physics Division Theory of Food Systems

A MATHEMATICIAN OR THEORETICAL PHYSICIST

Higher Scientific Officer

is required to join the Process Physics Division in the Institute. The successful candidate will have a strong interest in the rheology of both Newtonian and non-Newtonian materials and use both analytical and numerical mathematical methods to gain an understanding of their behaviour in both rheometric and non-rheometric situations. A strong commitment to relating the results to experiments is essential.

Qualifications: 1st or upper 2nd class honours degree in Physics or Applied Mathematics and at least two years' relevant post-graduate experience, preferably a PhD, in Theoretical Physics or Applied Mathematics with experience in fluid mechanics, rheology or statistical mechanics.

Salary: On a scale £7,149-£9,561 (under review). Non-contributory superannuation scheme.

The Agricultural and Food Research Council is an Equal Opportunities Employer.

Further particulars and application form from the Secretary, Food Research Institute, Colney Lane, Norwich NR4 7UA, quoting reference no. 84/ NP/ 7.

Closing date: 8th June 1984

(2090)A

GERMAN CANCER RESEARCH CENTER HEIDELBERG

CELL/ MOLECULAR BIOLOGIST

A postdoctoral position (2 years initially is available to join a research group working on the control of gene expression. The research will focus on the tissue specific expression of the chicken lysozyme gene and the rat tyrosine aminotransferase gene and its control by steroid hormones and cAMP. Applicants with experience in molecular and cell biology and/or somatic cell genetics will be preferred.

Applications with full CV, description of scientific experience and the names of two referees should be sent to: Prof. Dr. Günther Schütz, Institute of Cell and Tumor Biology, German Cancer Research Center (DKFZ), Im Neuenheimer Feld 280, D - 6900 Heidelberg, F.R.G. (W998)A

POSTGRADUATE RESEARCH IN GEOLOGY

(2 POSTS)

Salary £5649 — £6363
Pay award pending

Applications are invited from candidates with, or expecting to obtain a good honours degree in either Geology (for both projects) or joint Geology/Chemistry (for project 2) for the following: —

1. Structure, lithostratigraphy and sedimentology of the Lower Devonian rocks of South Devon.
2. Temporal and spacial variations in the chemistry and mineralogy of historic larvas from Mount Etna, Sicily.

Research Assistants are expected to register for a CNAA higher degree. Appointments are for a period of two years with a possibility of a third year (fixed term contract).

Further details and application forms to be returned by Friday 15th June 1984 can be obtained from the Personnel Office, Plymouth Polytechnic, Drake Circus, Plymouth PL4 8AA. Tel: (0752) 264639 (NB Please specify clearly for which project you are applying). (2081)A

Plymouth Polytechnic

UNIVERSITY OF OXFORD

DEPARTMENT OF BIOCHEMISTRY

POST-DOCTORAL RESEARCH ASSISTANT GRADE RS1A

(Ref: B/R/106)

A Post-doctoral Research Assistant is required to work with Drs A J and S M Kingsman on the control of gene expression and plasmid replication in Saccharomyces cerevisiae. The post is available for three years. The salary will be on the scale £7,190 — £9,425 according to qualifications and experience and with membership of USS.

Applications, including a full curriculum vitae and names and addresses of two referees, should be sent by 30th June 1984 to The Administrator at the address below.

DEPARTMENTAL DEMONSTRATORSHIP

(Ref: B/D/105)

It is proposed to appoint a Departmental Demonstrator from 1st October, 1984, or as soon as possible thereafter and preference may be given to candidates whose interests are in physical biochemistry. The successful candidate will be expected to take part in departmental teaching and to conduct his or her own research. The appointment is for a period not exceeding three years in the first instance. The salary will be on the scale £6,310 — £8,975 pa according to qualifications and experience and with membership of USS.

Applications (3 copies), including the names and addresses of two referees, should be sent, not later than 30th June, 1984, to The Administrator, Department of Biochemistry, South Parks Road, Oxford OX1 3QU. (2146)A

JOHN INNES INSTITUTE

PLANT MOLECULAR BIOLOGIST & CELL BIOLOGIST

Higher Scientific Officers, Band 1

Applications are invited for two posts to extend the Institute's programme in molecular plant pathology. Both posts are for three years duration.

The appointees will collaborate with other members of the Norwich Molecular Plant Pathology Group (NOMPAG), consisting of members of the John Innes Institute staff and faculty of the School of Biological Sciences, University of East Anglia, who are applying a range of molecular biological techniques to selected problems in plant pathology.

It is envisaged that Post 1 will be filled by a molecular biologist/biochemist who will investigate and isolate plant genes which are expressed following infection by pathogens, while Post 2 requires a cell biologist to investigate (probably by immunochemical procedures plant cell wall structure with particular reference to the possible involvement of wall polymers in host-pathogen recognition reactions. Further details may be obtained from Dr M J Daniels (Post 1) and Dr K Roberts (Post 2).

Applicants should have a good honours degree, with ideally a PhD and post-doctoral training in a relevant area of biology. Salary will be dependent on age and experience, on the Higher Scientific Officer scale in the range of £7149-£9561 (pay award pending). The John Innes Institute is an Equal Opportunities Employer.

In accordance with the provision of the Employment Protection (Consolidation) Act 1978, staff on short term appointments are required to waive any statutory rights to redundancy payments or to make claims of unfair dismissal, in respect of dismissal at the end of the three years project.

Applications giving full particulars and experience together with the names of two referees should be sent to the Secretary, John Innes Institute, Colney Lane, Norwich, Norfolk NR4 7UH, England quoting reference Gen/161 (Post 1) or CB/162 (Post 2) by 16 July 1984. (2093)A

IMPERIAL COLLEGE

DEPARTMENT OF CHEMISTRY

Applications are invited for a

POST-DOCTORAL RESEARCH ASSISTANT

for two years starting from 1 September 1984 to work with Professor W J Albery and Professor B C H Steele on porous oxide electrodes.

Applications including a curriculum vitae and the names of two referees should be sent as soon as possible to Professor W J Albery, Department of Chemistry, Imperial College, London SW7 2AY. (2123)A

POSTDOCTORAL POSITION AND PROJECT LEADER — PARASITOLOGY (Cattle tick vaccines)

vailable immediately to develop a accine for the control of the cattle ick Boophilus microplus. The roject is funded for two years with n option for extension. Preference o applicants with expertise in mmunology.

Salary per annum $A24,353 with superannuation and reasonable emoval expenses. Ref 18884.

Applications to the Staff Officer, niversity of Queensland, 4067, St ucia, Australia, by June 15, 1984. lease supply names of three referees nd submit a separate application for ach position. (W1009)A

ROYAL FREE HOSPITAL SCHOOL OF MEDICINE (University of London)

ACADEMIC DEPARTMENT OF HAEMATOLOGY

"NEW BLOOD" LECTURESHIP IN MOLECULAR BIOLOGY

Applications are invited for a Molecular Biologist with an interest in the broad field of genetic and acquired haematological disorders. A research group will be formed around a suitable candidate. Some teaching at undergraduate and post-graduate levels will be expected. Major research interests of the Department at present include leukaemia, lymphoma, stem cells, haemophilia and other haemostasis disorders. Post tenable from October 1984.

Salary on scale £7,190-£14,125 (under review) plus £1,186 London Allowance with superannuation benefits. The age of the successful candidate should not normally be over 35 at the date of appointment. Eight copies of curriculum vitae and names of two referees to be sent by 15 June 1984 to the School Office, RFHSM, Rowland Hill Street, London NW3 2PF, (01-794 0500 ext 4262) from which further details may be obtained. (2110)A

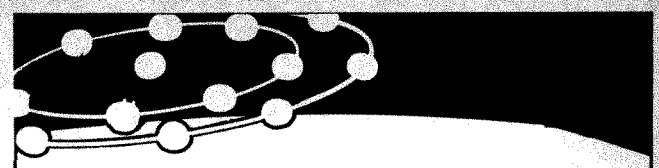
UNIVERSITY OF EDINBURGH

POSTDOCTORAL POSITIONS IN MOLECULAR BIOLOGY

Scientists with expertise in immunochemistry/hybridoma technology and gene manipulation are required to join a team engaged in identification and cloning of genes for clinically important antigens of a human malaria parasite.

Send cv and the names of two referees to: Dr J G Scaife, Department of Molecular Biology, Darwin Building, Edinburgh University, King's Buildings, Mayfield Road, Edinburgh EH9 3JR. (1974)A

UNIVERSITY OF ABERDEEN



DEPARTMENT OF MICROBIOLOGY

TEMPORARY LECTURESHIP

The Department of Microbiology invites applications for a Temporary Lectureship for one year from October 1984. The post arises from the award of the Nuffield Research Fellowship to Dr I R Booth, and the successful applicant will be expected to assist with teaching in microbial physiology, genetics and molecular biology. There will be the opportunity also to carry through a research programme.

Salary within the range £7,190 to £8,530 per annum, on lecturers salary scale (under review).

Further particulars and application forms from the Secretary, The University, Aberdeen, with whom applications (2 copies) should be lodged by 15 June, 1984. (2139)A

The European Molecular Biology Laboratory, a research institute situated in Heidelberg, West Germany, invites applicants for the following vacancies at the Laboratory's Outstation at the Deutsches Elektronen-synchrotron (DESY) site in Hamburg

APPLICATIONS PROGRAMMER

The successful candidate will help the scientists at the Outstation to design, develop and maintain data acquisition and application programmes for the synchrotron radiation experiments at the Outstation which include protein crystallography, time resolved scattering and X-ray spectroscopy (EXAFS) on biological systems.

He/she will also be expected to take part in the daily operations of the computers at the Outstation: VAX 11/750, PDP 11/45, PDP 11/24. Computer network access is used to maintain collaboration with other groups. Since a large number of projects are carried out by visiting workers, an ability to interact with people is indispensable.

An interest in applying computer technology to scientific problems is indispensable and previous programming experience in a scientific environment will be an asset. The ideal candidate would have at least 3 - 5 years experience using one or more high level languages (FORTRAN, PASCAL). Knowledge of assembler for PDP 11 or VAX is an advantage.

The net salary offered will be around DM 3900, - monthly. Certain allowances are payable in addition, depending on personal circumstances.
An initial contract of 3 years' duration, which can be renewed, will be offered.

Please write briefly for an application form quoting reference N°84/23 to:

THE UNIVERSITY OF LANCASTER

Department of Environmental Sciences

The Ionosphere Group of the Environmental Sciences Department has a vacancy for a RESEARCH ASSOCIATE to work on problems of the ionosphere at high latitudes. The project is supported by the Science and Engineering Research Council and the salary will be at an appropriate point on Research Scale IA which commences at £7190 p.a. (currently under review). The appointment is for one year.

Applications are invited from PhD level physicists or geophysicists with interests in radiowave propagation or ionospheric physics.

Further particulars may be obtained (quoting reference L065/ B) from the Establishment Office, University House, Bailrigg, Lancaster, LA1 4YW, where applications (six copies) naming three referees, should be sent NOT LATER THAN 7 JUNE 1984.

(2143)A

Molecular/Cell Biologist

Atomic Energy of Canada Limited invites applications for a staff scientist to join the Radiation Radiology Branch at the Chalk River Nuclear Laboratories. Candidates should possess a Ph.D. degree and preferably have post doctoral experience. This is a continuing position and the successful applicant will be expected to establish an independent research program in an area complementary to the interests of the existing group of ten scientists. The branch research program is internally funded. It focuses on mechanisms of DNA damage and genetic and external factors which influence these processes. Present programs on hyperthermia, mutagenesis, and tumor induction and promotion support these aims. Excellent small animal facilities are available.

Atomic Energy of Canada Limited is a Crown Corporation and first preference will be given to Canadian citizens and landed immigrants of Canada; however, foreign nationals are also invited to apply.

CRNL offers a competitive compensation package and the opportunity to work and live in a pleasant and attractive resort area of the Ottawa Valley, 190 kilometres northwest of Ottawa on the Ottawa River. Good education facilities and year round cultural and recreational facilities are available in the Deep River/Pembroke area.

Qualified women and men should send a complete resumé, including the names of three references and quoting file P-8412 to:

UNIVERSITY OF EDINBURGH

DEPARTMENT OF VETERINARY PHYSIOLOGY

"WELLCOME" LECTURESHIP IN VETERINARY SCIENCE

Applications are invited for a post of Lecturer in the Department of Veterinary Physiology, tenable for a period of three years in the first instance, with possible renewal for a further two years, and available from 1st October 1984. Candidates should be aged 35 or under and should not currently hold a permanent university appointment.

The "Wellcome" lectureships are primarily for research. The appointees will be expected to contribute through fundamental research to understanding of the mechanisms underlying pain and analgesia and to investigate methods for the assessment and alleviation of pain in domestic animals. The successful applicant should bring to this post neurophysiological and neuropharmacological expertise as well as an interest in the welfare of domestic animals.

The initial salary will be at an appropriate point on the lecturer scale £7,190-£12,080 pa.

Applications (3 copies) must include a 500 word summary of the candidate's proposed research, a curriculum vitae with details of research and teaching experience and the names of two referees. Written enquiries should be addressed to Professor A Iggo, Department of Veterinary Physiology, from whom further details may be obtained.

Applications should be submitted to the Secretary of the University, Old College, South Bridge, Edinburgh EH8 9YL before Saturday, 16th June.

Please quote Reference 1126. (2099)A

UNIVERSITY OF CAMBRIDGE

DEPARTMENT OF CLINICAL VETERINARY MEDICINE

Applications are invited for a

LECTURER OR ASSISTANT LECTURER

under the UGC 'New Blood' Scheme. The age limit for 'new blood' appointments is thirty-five, but in exceptional cases candidates just over the age limit may be considered. Preferably applicants should have a veterinary degree, but applications will be considered from applicants with non-veterinary qualifications. The successful candidate will be expected to develop research in respiratory pathophysiology in relation to metabolic consequences of pulmonary damage in farm animals, and to investigate respiratory mechanisms and to correlate structural and functional changes in the lung in relation to the systematic effects of disordered lung function on growth and metabolism. The Department already has ongoing research on the pathogenesis of respiratory disease in calves and the effect of respiratory diseases on pigs.

Tenure: University Lecturer and Assistant Lecturer. Appointment will be for three years with the possibility of reappointment to retiring age in the case of a Lecturer, for an Assistant Lecturer reappointment for two years.

Stipends: University Lecturer: £9,875 rising by eleven annual increments to £15,085: there is no grade of Senior Lecturer.

University Assistant Lecturer: £7,630 rising by four annual increments to £9,425.

Applications should be sent to the Secretary of the Appointments Committee for the Department of Clinical Veterinary Medicine, Madingley Road, Cambridge CB3 0ES, (twelve copies) and should include a curriculum vitae, list of publications, and the names of not more than three referees, to reach him not later than 4 June 1984. (2106)A

UNIVERSITY OF DUNDEE

DEPARTMENT OF PATHOLOGY

POSDOCTORAL RESEARCH ASSISTANT

Applications are invited from cellular immunologists or biologists for appointment for a period of one year in the first instance to work in the Clinical Immunology Laboratory in the above Department on a study of the effect of UVC irradiation of blood on immune competence. Experience in techniques of cellular immunity, tissue culture, flow cytofluorimetry and/or the assay of antibody levels would be useful.

Salary £7190 per annum (under review). Superannuation under Universities Superannuation Scheme.

Further particulars are available from the Personnel Officer, The University, Dundee, DD1 4HN with whom applications containing full career details and the names of 2 referees should be lodged by 14th June 1984. Please quote reference EST/57/84(J). (2116)A

ROYAL MILITARY COLLEGE OF SCIENCE (RMCS) Shrivenham

DEPARTMENT OF MATHEMATICS AND BALLISTICS

RESEARCH SCIENTIST IN COMPUTATIONAL MATHEMATICS

Applications are invited for the post of Research Scientist to work on a project concerned with the computer modelling of fracture problems. The main task of the appointee will be to develop an existing suite of programs into an integrated and flexible software package. The opportunity exists for a suitable candidate to make a significant contribution to research, and it may therefore be possible to register for a higher degree in connection with the work.

The successful candidate is likely to have a good degree with a substantial mathematics and/or computing content. A good knowledge of scientific programming is required and experience in the use of FORTRAN would be an advantage. The person appointed will work in the Department of Mathematics and Ballistics as a member of a team of four within the Computational Mathematics group. Liaison with government research establishments is involved, and opportunities exist for relevant travel, attendance at conferences and publication of results.

The appointment is for a period of one year in the first instance in the grade of Research Scientist (salary scale £5,460 — £8,530 depending on qualifications and experience).

From 1 August 1984, RMCS will become a faculty of the Cranfield Institute of Technology.

Application forms and further information may be obtained from the Civilian Admin Office, Royal Military College of Science, Shrivenham, Swindon, Wilts SN6 8LA. Tel (0793) 782551, ext 421. Please quote reference No HQ 120/1/191.

Closing date for applications 15 June 1984. (2147)A

SOUTHAMPTON AND SOUTH WEST HAMPSHIRE HEALTH AUTHORITY

BASIC GRADE BIOCHEMIST

To work with University Geriatric Medical team based at Southampton General Hospital, linked to Professor Barbara Clayton's department of Chemical Pathology and Human Metabolism. This is a research post, the main interests being bone disease in the elderly and neurochemistry of ageing. Some experience of radioimmunoassay and/or receptor-binding techniques would be an advantage.

Salary Scale (post probationer £6,520 — £8,349). Application form and job description from District Personnel Department, Tremona Court, 30/32 Tremona Road, Southampton. Telephone Southampton 777222 ext 3018/3556. Closing date 8 June 1984. (2149)A

Nestlé

Our Central Research Department in Vevey/Switzerland is seeking a

chemist or biochemist

to work in the protein field.

Activity

- Analysis of food proteins by electrophoretic and chromotographic techniques.
- Extraction, fractionation and purification of proteins from various raw materials on laboratory and pilot plant scale.
- Study of physicochemical and functional properties of food proteins.

Qualifications required

- University degree with Ph.D.
- Experience in protein purification and characterization.

Please send your application for employment with curriculum vitae and photograph to:

Miss Myriam Germanier
Personnel Services,
Nestlé Products Technical Assistance Co. Ltd.,
1800 Vevey / Switzerland. (W997)A

Nestlé

UNIVERSITY OF CAPE TOWN

Senior Lecturer in Physical Oceanography

Applications are invited for the above post, vacant from 1 July 1984.

Candidates should have interests in the broad field of dynamical oceanography, those with interests in air-sea interaction and/or marine climatology being particularly welcome. The successful applicant will be required to take part in undergraduate and postgraduate teaching and to undertake research.

Appointment, according to qualifications and experience will be made on the salary scale R16 557 x 936–24 045 plus a pensionable allowance of 12%, with an annual bonus of nearly one month's salary and attractive staff benefits.

Applicants should submit a full curriculum vitae and the names and addresses of three referees not later than 15 June 1984 to the Registrar, (Attention: Appointments Office) Department AC/452, University of Cape Town, Private Bag, Rondebosch, 7700, South Africa. Further information may be obtained from the Registrar or The Secretary, SA Universities Office, Chichester House, 278 High Holborn, London WC1V 7HE.

The University's policy is not to discriminate on the grounds of sex, race or religion. Further information on the implementation of this policy is obtainable on request.

FSR 0641 (W1001)A

Protein Chemist

G.D. Searle is a major international pharmaceutical company with a strong commitment to Research & Development in the UK. The Company is actively involved in the fields of chemically and biologically derived medical products.

A vacancy has arisen for an experienced Protein Chemist to join a group working on the purification and characterisation of genetically engineered proteins. Applications are invited from post graduates with a minimum of 3 years relevant experience which ideally would include specialised experience of protein structure and folding.

The Company offers:—

* 37½ hour working week
* 23 days basic holiday entitlement
* subsidised restaurant
* generous health insurance
* contributory pension scheme
* active recreation club

Please apply to Miss D. Wardman, Assistant Personnel Officer, Searle Research & Development, Lane End Road, High Wycombe, Bucks (Tel: High Wycombe 21124, ext 3254). Please quote reference PR21. (2103)A

DEPARTMENT OF OBSTETRICS & GYNAECOLOGY

"NEW BLOOD" LECTURESHIP NON-CLINICAL MILECULAR GENETICS IN HUMAN REPRODUCTION

Applications are invited for the above post which will be tenable in the Harris Birthright Research Centre for Fetal Medicine in the Department of Obstetrics and Gynaecology. Candidates (normally under 35 years of age) should have a higher degree and experience in recombinant DNA technology. The successful applicant will be expected to apply these methods to the department's current research on pre-natal diagnosis and in vitro fertilisation and also contribute to teaching.

Salary on the scale for non-clinical lecturers £7190-£14,125 plus £1186 London Weighting Allowance per annum.

Further details may be obtained from the Secretary, King's College School of Medicine & Dentistry, Denmark Hill, London SE5 8RX, to whom applications, giving the names and addresses of three referees, should be sent no later than Thursday 14 June 1984. (2089)A

SCOTTISH UNIVERSITIES RESEARCH AND REACTOR CENTRE

POST OF DIRECTOR

The Centre was opened in 1963 to provide research and teaching facilities in the reactor field for the Scottish Universities. Since then the range of its activities has widened to include isotope geology and nuclear medicine.

The Directorship of the Centre will become vacant on the retiral of Professor H W Wilson on 30th September, 1985. Applications are invited from suitably qualified persons for this post which is on the professorial salary scale. The successful candidate will probably be a physicist, chemist, isotope geologist or engineer with experience in the broad areas of reactor science and engineering, isotope geology or nuclear medicine, in all of which fields the Centre has an established reputation. The Director will be expected to be the scientific leader of the Centre.

Further particulars may be obtained from the Academic Personnel Office, University of Glasgow, Glasgow G12 8QQ, where applications (3 copies; 1 copy in the case of overseas applicants), giving the names and addresses of not more than three referees, should be lodged on or before 30th June, 1984.

In reply please quote Ref No 5256M. (2124)A

Royal Postgratduate Medical School

WELLCOME LECTURESHIP IN VIROLOGY

Applicatons are invited from candidates trained in the techniques of modern molecular biology, such as the M13 (Sanger) cloning sequencing system, site-specific mutagenesis, and molecular cloning, for a new post of Wellcome Lecturer in the Department of Virology. The successful candidate will be required to develop the application of molecular biological techniques in a clinical environment and to contribute to the teaching activities of the Department.

Candidates should be not more than 35 years of age and must not hold a permanent university appointment in the United Kingdom. Appointment will be for three years in the first instance with a possible extension for a further two years. Salary on the non-clinical lecturer scale, currently £7,190 — £14,125 plus £1,186 London Allowance.

Applicants should apply by letter, enclosing 6 copies of their curriculum vitae, a statement of not more than 500 words on the research they would propose to undertake if appointed, and naming three referees to: The Deputy Secretary, Royal Postgraduate Medical School, Hammersmith Hospital, DuCane Road, London W12 0HS, from whom further particulars can be obtained (telephone: 01-743 2030, ext. 263).

Closing date for applications: 15 June 1984. (2085)A

THE UNIVERSITY OF SYDNEY
DEPARTMENT OF BIOCHEMISTRY

LECTURESHIP

Duties will consist of teaching and research. The Department teaches Biochemistry to students in the following courses: Dentistry, Medicine, Science, Pharmacy and Veterinary Science. Applications are invited from persons suitably qualified in Biochemistry: preference may be given to those with special interest in the area of th eukaryotic gene structure and expression.

Salary range: $A23,394 - $A30,734 pa (under review).

Appointments to Lectureships are usually probationary for three years and the University reserves the right not to proceed with any appointment for financial or other reasons.

Applications, quoting reference no 18/07 and including curriculum vitae, list of publications and names of three referees to the Registrar, University of Sydney, NSW 2006 Australia by 15 June 1984, from whom further information available. Further general information also available from Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF. (W1004)A

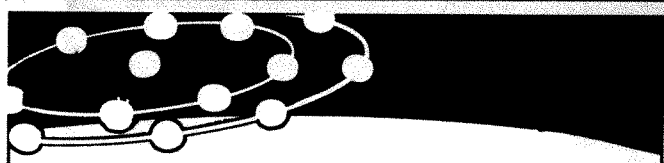
UNIVERSITY OF CAMBRIDGE

LECTURER IN THE DEPARTMENT OF METALLURGY AND MATERIALS SCIENCE

To take up appointment of 1 October 1984 or as soon as possible thereafter. Preference will be given to candidates with research experience in the science and engineering aspects of composite materials. The lecturer will be expected to teach in the broad field of non-metallic materials.

The appointment will be for three years with the possibility of reappointment to the retiring age. The pensionable scale of stipends for a University lecturer, not ordinarily resident in college, is £9875 rising by eleven increments to £15085.

Further information about the duties and conditions of appointment may be obtained from the Secretary of the Department of Metallurgy and Materials Science, Pembroke Street, Cambridge CB2 3QZ. Applications, including the names of three referees, should be sent to Secretary of the Faculty of Physics and Chemistry, Institute of Astronomy, Madingley Road, Cambridge, so as to reach him not later than 27 June 1984.



(2145)A

UNIVERSITY OF DUNDEE
WELLCOME LECTURESHIP IN PHYSIOLOGY

PHYSICAL CHEMIST/ BIOCHEMIST/ PHYSIOLOGIST

Applications are invited for the above full-time post tenable in the Department of Physiology, University of Dundee, for up to five years from September 1984. Candidates must be under 35 years of age and not presently hold a permanent position in a University or research establishment within the United Kingdom. A condition of appointment is that, besides carrying out teaching to Medical and Science students, the successful candidate will be expected to work with Professor M J Rennie in the general area of physiological metabolism on the development and application of stable-isotope-labelling techniques suitable for use in studies of human physiology and medicine. Preference will be given to candidates with previous experience of stable-isotope methodology who can demonstrate an ability to apply this expertise to physiological problems or to physiologists who are willing to make themselves expert in methodologies involved.

Further particulars are available from the Personnel Officer, the University, Dundee, DD1 4HN (telephone 0382 23181 extension 383) and prospective applicants are requested to obtain these before submitting formal applications and outlines of the research projects they have in mind to undertake with Professor Rennie. Please quote reference EST/17/84(J). (2115)A

The European Molecular Biology Laboratory, a research institute situated in Heidelberg, West Germany, invites applicants for the following vacancies at the Laboratory's Outstation at the Deutsches Elektronen-synchrotron (DESY) site in Hamburg.

PROTEIN CRYSTALLOGRAPHER

The Outstation has developed advanced instrumentation for the use of synchrotron X-ray radiation in structural biology Protein Crystallography, fibre and solution diffraction, X-ray spectroscopy (EXAFS). The facilities are used by many groups mainly from the Member States. The successful candidate will be expected to engage in research projetcs, making use of the outstanding properties of synchrotron radiation (high intensity, wavelength tunality, polarization and time structure) for protein crystallography. Besides these activities, she/he will also assist outside groups with protein crystallographic data collection.

The ideal candidate would be a protein crystallographer with 3-5 years of experience, capable of carrying out the various aspects of a crystallographic project. Fluent knowledge of English is a prerequisite.

The net salary offered will be between DM 3900, - and DM 4700, - monthly. Certain allowances are payable in addition, depending on personal circumstances. An initial contract of 3 years' duration, which can be renewed, will be offered.

Please write briefly for an application form quoting reference N°84/24 to :

Postfach 10.2209,
D-6900 Heidelberg

(W1000)A

UNIVERSITY COLLEGE OF LONDON
DEPARTMENT OF CHEMICAL AND BIOCHEMICAL ENGINEERING

A POST-DOCTORAL MEMBRANE BIOCHEMIST/ MICROBIOLOGIST

is sought to join a team supported by a Special Rolling Grant from the Science and Engineering Research Council. The programme is concerned with biochemical engineering studies to improve the processing of proteins and enzymes, and one of its objectives is to facilitate the large-scale isolation of membrane-associated enzymes. This project has been under way for five years and is presenting the biochemical engineers and bioscientists involved with new and exciting challenges. The present phase of work is funded until 1987. The team is part of a larger, internationally respected group of UCL engaged in enzyme, fermentation and protein technology studies and which has strong external links to relevant biochemistry, microbiology and genetics research teams.

Salary in range £7190 — £9425 per annum plus £1186 per annum London Allowance.

Applications should be addressed to Dr Peter Dunnill, Department of Chemical and Biochemical Engineering, University College London, Torrington Place, London WC1E 7JE, England. (2084)A

UNIVERSITY OF PENNSYLVANIA
School of Medicine
DEPARTMENT OF PATHOLOGY AND LABORATORY MEDICINE

SENIOR CELLULAR AND/OR MOLECULAR IMMUNOLOGIST

Applications are invited for a senior, tenured faculty position to head the Division of Research Immunology in the Department of Pathology and Laboratory Medicine.

The individual sought should possess a record of research achievement in cellular and/or molecular immunology and have demonstrated capability in research training. This person will be expected to continue the development of this established, nationally recognized research and training program, including recruitment of new members. No clinical service responsibilities are required of this position.

Interested candidates should submit résumés and names of three references prior to July 15, 1984 to Drs Leonard Jarett and Peter C Nowell, Co-Chairmen, Immunology Search Committee, Department of Pathology and Laboratory Medicine, University of Pennsylvania School of Medicine, Philadelphia, Pennsylvania 19104.

The University is an Affirmative Action/Equal Opportunity employer. (NW549)A

ST. GEORGE'S UNIVERSITY SCHOOL OF MEDICINE

GRENADA ST.VINCENT BARBADOS

St. George's University School of Medicine, located in the West Indies, is expanding its present faculty. Applications are invited from PhDs or MDs.

Teaching positions are available at the level of instructor, assistant Professor or Associate Professor, in the following subjects: Biochemistry, Microbiology. Lecturers and laboratory demonstrators in Pathology, Pharmacology, Physiology, Histology.

Recent retirees in good health, and experienced lecturers available during a sabbatical leave of at least one year will also be considered. Priority will be given to applicants with prior experience in lecturing in Medical Schools. These faculty appointments will begin July or August 1st 1984.

Submit applications including current curriculum vitae and recent references to the Vice Chancellor, St. George's University School of Medicine, c/o 849 Lullwater Parkway, Atlanta GA. 30307, U.S.A. (W1002)A

ROYAL FREE HOSPITAL SCHOOL OF MEDICINE
(University of London)

POSTDOCTORAL PHYSIOLOGIST

A three year MRC funded post for a postdoctoral candidate with a background in mammalian physiology will become available from October 1 1984, to work on circulatory reflexes with Professors M de B Daly and K M Spyer.

Salary on Scale Research 1A.

Further details are available from the School Office, Room G650, RFHSM, Rowland Hill Street, London NW3 2PF or telephone 01-794 0500 Extn 4262, to which application by full curriculum vitae, including the names and addresses of two referees, should be submitted by 8 June 1984. Please quote reference: S/RA. (2131)A

Sutton, Surrey SM2 5PX

POSTDOCTORAL CHEMIST

Applictions are invited from a Postdoctoral Biochemist for a research post in a group studying the biology of the human breast. The post will involve predominantly the characterisation of intermediate filaments in a human breast epithelial cells and the successful applicant will be a member of an integrated team of biologists, membrane biochemists and pathologists investigating differentiation in this system. Practical experience of protein separation techniques including two dimensional gel electrophoresis is essential. Tissue culture experience would be an advantage but not essential as the opportunity to learn this and monoclonal techniques would be provided in the course of the project.

The post will be classified as Non-Clinical Scientist Grade II (MRC Scale) and salary range within £7,190-10,710 pa plus £1,1865 pa London Weighting.

Applications should be sent in writing, enclosing curriculum vitae and the names and addresses of two referees to the Administrator at the above address before 8th June 1984. (2083)A

THE PAPUA NEW GUINEA UNIVERSITY OF TECHNOLOGY

LECTURER IN DEPARTMENT OF APPLIED PHYSICS

Applications are invited for the post of Lecturer in the Department of Applied Physics.

The appointment is of 3 years duration during the absence of a national staff member on study leave.

The appointee will be expected to teach general physics in service courses in addition to advanced teaching and research. A qualification in geophysics is preferred.

Salary: Lecturer I K16,820 per annum; Lecturer II K18,670 per annum (K1 = Stg 0.8209) (Level of appointment will depend upon qualifications and experience).

The initial contract period is for approximately three years. Other benefits include a gratuity of 24% taxed at 2%, appointment and repatriation fares, leave fares for the staff member and family after 18 months of service, settling-in and settling-out allowances, six weeks paid leave per year, education fares and assistance towards school fees, free housing, salary protection plan and medical benefit schemes are available.

Detailed applications (two copies) with curriculum vitae, together with the names and addresses of three referees and indicating earliest availability to take up appointment should be received by: The Registrar, Papua New Guinea University of Technology, Private Mail Bag, Lae, Papua New Guinea, by 15 June 1984.

Applicants resident in the United Kingdom should also send one copy to Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H OPF, from whom further general information may be obtained. (W1010)A

CHARING CROSS HOSPITAL MEDICAL SCHOOL
(University of London)

POSTDOCTORAL RESEARCH FELLOW

Applications are invited for this post in the Department of Biochemistry to work on an MRC-funded project on the effect of oestrogens on proteoglycan synthesis in connective tissue cells. Applicants should have obtained a PhD degree and preferably have some experience in cell culture techniques.

Starting salary £7,190-£7,630 pa plus £1,186 pa London Allowance.

Informal enquiries to Dr R Mason, 01-748 2040 ext 2604/2841.

Applications should include a full curriculum vitae and the names and addresses of two referees, to be sent to The Secretary, Charing Cross Hospital Medical School, The Reynolds Building, St Dunstan's Road, London W6 8RP, by 20th June. (2132)A

THE UNIVERSITY OF BIRMINGHAM
FACULTY OF MEDICINE AND DENTISTRY
DEPARTMENT OF CANCER STUDIES

POST-DOCTORAL CELL BIOLOGIST/ IMMUNOLOGIST

A vacancy exists for a post-doctoral scientist with experience in cell biology/immunology to join a research group studying cellular transformation by the Epstein-Barr virus. The project, which will be carried out in the Department's new laboratory, is funded for up to three years by the Cancer Research Campaign. The position is available immediately, although consideration may be given to applicants who are completing postgraduate work later this year. Further details are available from Professor A B Rickinson of the above Department (021) 472 7607.

Salary on scale Research Fellow 1A £7,190-£11,615 with superannuation.

Applications (three copies) with names of two referees to Assistant Registrar, Medical School, Birmingham, B15 2TJ by 14th June 1984. Quote ref: RF/CS/Imm. (2095)A

RESEARCH OFFICER

for protein crystallization studies. Our work on the crystal structure of enzymes, especially of modified enzymes created by protein engineering, demands greater effort in protein crystallization. We seek an applicant with an understanding of the properties of protein molecules in solution, and with wide practical experience in protein chemistry. A good honours degree in Biochemistry, or the equivalent, and some years postgraduate experience in relevant work are expected. An applicant for part-time work would be considered.

The appointment will be in the ORS IB range £6310-£9875 + £1186 London Allowance, and will be funded by MRC to August 1987 in the first instance.

Applications, including a CV and the names of two referees, should be addressed to Professor D M Blow, FRS, Blackett Laboratory, Imperial College, London SW7 2BZ. (2120)A

MONASH UNIVERSITY
Melbourne, Australia
DEPARTMENT OF BIOCHEMISTRY
FIXED-TERM LECTURER (3-5 YEARS)

Postdoctoral graduate to teach science or medical students and participate in ongoing research programme into physical biochemistry of connective tissues. Candidates should have a general background in biochemistry/chemistry with research experience in techniques of physical biochemistry. Applicants with experience in polymer research preferred, but this is not essential.

Enquiries to Professor A W Linnane.

Salary: $A24,353—$A31,994 pa.

Applications including Ref no 30212, curriculum vitae and 3 referees to the Registrar, Monash University, Clayton, Vic 3168, Australia, with a copy to the Secretary General, Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF, by 1/8/84, from whom Conditions of Appointment available.

An equal opportunity employer. (W1003)A

THE UNIVERSITY OF NORTH CAROLINA
DEPARTMENT OF MICROBIOLOGY AND IMMUNOLOGY
RESEARCH ASSOCIATE

Available immediately for postdoctoral scientist to participate in studies of pathogenic RNA virus gene expression and function using recombinant DNA technology.

Send curriculum vitae and 3 letters of reference to Dr G W Wertz, Department of Microbiology & Immunology, University of NC, Chapel Hill, NC 27514.

The University of NC is an Equal Opportunity/Affirmative Action Employer. (NW546)A

UNIVERSITY OF WARWICK
LECTURESHIP IN BIOTECHNOLOGY (PLANT BIOCHEMISTRY)

Applications are invited for a lectureship in the Department of Biological Sciences from persons with a PhD in biochemistry, genetics, or related subjects interested in applying modern biochemical techniques, especially recombinant DNA technology, to study the expression of genes for plant proteins especially with the aim of producing mutant forms of toxic and allergenic proteins. The appointee will be expected to develop his or her own research programmes and to teach in undergraduate courses. Initial salary will normally be within the first six points of the Lectureship scale: £7,190 — (£9,425) — £14,125 pa. Further particulars and application forms from the Registrar, University of Warwick, Coventry CV4 7AL quoting Ref. No: 42/A/84/O. Closing date for receipt of applications 15th June, 1984. (2148)A

ASSISTANTSHIPS

UNIVERSITY OF GLASGOW
Department of
Electronics and Electrical Engineering

Research Assistantships (JOERS)

Applications are invited for three Research Assistantships supported by S.E.R.C. on research grants awarded under the Joint Optoelectronics Research Scheme.

1. **$LiNbO_3$ Integrated Optical Devices:** to work on novel optoelectronic switching and modulation devices for operation at microwave and millimetre wave frequencies, with applications in high-capacity optical fibre telecommunications and microwave radar systems.
2. **Modular Beam Epitaxy of III-V Semiconductors:** for applications in advanced optoelectronic device structures.
3. **Coherent Optical Signal Processing:** applied to the homodyne receiver. Modelling, theoretical analysis and experimental assessment of various types of optical homodyne phase-locked loops using frequency, phase and amplitude modulated signals.

Those appointed will join an established research group with excellent support facilities, and will work in close co-operation with the academic and industrial partners in each JOERS project. Applicants should possess a Ph.D. or have equivalent research experience in electronic engineering, physics or materials science. Starting salary up to £9,875 (under review) on the 1A scale for research staff. The posts are tenable for two or three years in the first instance, subject to satisfactory progress. Applications (3 copies) stating qualifications and experience and naming two referees, to: Dr. P.J.R. Laybourn, Department of Electronics and Electrical Engineering, University of Glasgow, G12 8QQ from whom further particulars of the posts are available. (2134)P

IMPERIAL COLLEGE OF SCIENCE AND TECHNOLOGY

Applications are invited for a
POST-DOCTORAL RESEARCH ASSISTANTSHIP

in molecular biology for work on the development of plant gene vectors from virus replicons, involving DNA cloning and sequencing, transcriptional involving DNA cloning and sequencing, transcriptional mapping, in vitro translation and plant cell transformation. The appointment will be for 2 years from 1 October 1984 with the possibility of renewal for a further period. Salary in the range £8376-£9716 including London Allowance.

Applications, with names of two referees, to Dr K W Buck and Dr R H A Coutts, Department of Pure and Applied Biology, Imperial College, London SW7 2BB. (2121)P

FELLOWSHIPS

UNIVERSITY OF FREIBURG

Applications are invited for a
POSTDOCTORAL FELLOWSHIP IN NEUROCHEMISTRY

to study metabolism of neuropeptides in CNS and CSF.

Curriculum vitae and references should be sent to: Dr H Cramer, Professor, Section on Neurochemistry, Department of Neurology, Hansastr 9, D-7800 Freiburg, West Germany. (W1007)E

FRIEDRICH MIESCHER-INSTITUT
Basel, Switzerland

POSTDOCTORAL FELLOWSHIP IN PROTEIN BIOCHEMISTRY

Applications are invited for a postdoctoral position to study protein interactions involved in blood coagulation. It is envisaged that a wide range of techniques will be used, e.g. protein modification, binding and kinetic studies. Experience in protein purification together with protein chemistry of enzymology is desirable.

The position is available immediately for a period of one year with the possibility of renewal for a further two years.

Applications, including curriculum vitae and the names of two referees should be sent as soon as possible to Dr. S.R. Stone, Friedrich Miescher-Institut, P.O. Box 2543, CH-4002 Basel, Switzerland. (W1008)E

Continued on page 14

FELLOWSHIPS continued

UNIVERSITY OF GUELPH

UNIVERSITY FELLOWSHIPS

The College of Biological Science is enlarging its Research and Graduate Programs and invites applications from individuals interested in competing for NSERC University Fellowships. Candidates are reminded that they would be eligible for consideration for any tenure track position available following their appointment.

BOTANY
Growth and development of plants

MICROBIOLOGY
Bacterial cell envelope structure and function
Physiology of fish pathogens
Fermentation technology
Molecular biology of virus reproduction

MOLECULAR BIOLOGY & GENETICS
Cell and molecular biology of gene expression
Developmental biology
Genetic recombination

NUTRITION
Nutritional immunology
Nutritional toxicology
Food toxicology

ZOOLOGY
Comparative physiology particularly in marine systems
Fisheries ecology

SCHOOL OF HUMAN BIOLOGY
Human physiology
Physical anthropology
Ergonomics
Human biomechanics/bioengineering

Successful candidates would have the opportunity of participating in both the undergraduate and graduate teaching programs.

Applications, including a curriculum vitae, and the names of three referees should be forwarded, by August 1st, to:

Bruce H. Sells, PhD
Professor and Dean
College of Biological Science
University of Guelph
Guelph, Ontario
Canada N1G 2W1

In accordance with Canadian immigration requirements, priority will be given to Canadian citizens and permanent residents of Canada.

(NW545)E

UNIVERSITY OF EAST ANGLIA
Norwich

RESEARCH FELLOWSHIP IN CHEMISTRY (NUCLEAR MAGNETIC RESONANCE)

Applications are invited for a two-year Research Fellowship in nuclear magnetic resonance, to be held in the School of Chemical Sciences. Applicants should have experience of modern NMR methods of post-doctoral level. The emphasis of that experience should be in physical chemistry. The post will also involve some lecturing duties. The post is on the Research and Analogous 1A scale, at or below the fourth point (currently £8530 per annum).

Applications should be made to Professor R K Harris, School of Chemical Sciences, University of East Anglia, Norwich NR4 7TJ, and should include a curriculum vitae, list of publications, and the names and addresses of two academic referees. The closing date for applications is 30 June 1984. The appointment may commence on 1 October 1984.

(2141)E

ESF PROGRAMME OF RESEARCH FELLOWSHIPS IN TOXICOLOGY (PGT)

Short-term (up to 6 months) and Long-term (6 to 12 months) Research Fellowships (deadline: 30 June 1984) and Short-term (up to 1 month) Visiting Fellowships (no deadline) are offered to scientists working in European laboratories to go to laboratories in other European countries. No condition of age, level or field of training, provided the project contributes to furthering research in TOXICOLOGY in Europe.
Information and application forms can be obtained from: Dr. Bernard Munsch, European Science Foundation, 1, quai Lezay-Marnésia, F-67000 STRASBOURG, France; tel. (88) 35.30.63; telex 890440.

STUDENTSHIPS

UNIVERSITY OF NOTTINGHAM

SERC RESEARCH STUDENTSHIP IN PLANT ULTRASTRUCTURE

Applications are invited for a SERC Quota Research Studentship, to work on the ultrastructure of embryogenesis and seed formation in Arabidopsis, in the Department of Botany under the supervision of Dr L G Briarty, starting on October 1, 1984. The work forms part of a project being carried out with the European Space Agency on the effects of microgravity on cell ultrastructure and development.

Applicants should have, or expect to obtain, a first or upper second class honours degree in Botany, Biology or a related field, and some experience of electron microscopy. Requests for further information, and applications with the names of two academic referees, should be sent as soon as possible to Dr L G Briarty, Department of Botany, University of Nottingham, University Park, Nottingham NG7 2RD. (2100)F

UNIVERSITY OF STIRLING
DEPARTMENT OF BIOLOGICAL SCIENCE

SERC CASE STUDENTSHIP

Applications are invited for a three year PhD studentship to work on the changes of stomatal behaviour during the course of a growing season. The study will involve some field work and also physiological and biochemical investigations. The award is held co-operatively with Dr H G Jones of East Malling Research Station and will commence in October 1984.

Applications, enclosing a curriculum vitae and the names of two referees should be sent to Dr C M Willmer, University of Stirling, Department of Biological Science, Stirling FK9 4LA. (2137)F

UNIVERSITY OF OXFORD
DEPARTMENT OF HUMAN ANATOMY

MRC RESEARCH STUDENTSHIPS

Applications are invited from students possessing, or expecting to possess, a good Honours (First or Upper Second) degree for studentships in the following areas:

1) Intracellular calcium and the regulation of solute transport by small intestine (Dr C A R Boyd)

2) An analysis of gonadotrophic hormone gene expression in mutant mice using recombinant DNA technology (Dr H M Charlton)

3) Pattern formation in the developing nervous system (Dr T J Horder)

Applicants should forward a letter of application with a full curriculum vitae and the names of two referees to Dr S Bradbury, Acting Head of Department, Department of Human Anatomy, South Parks Road, Oxford OX1 3QX by Monday, 4 June. Interviews of selected candidates will be held on Wednesday, 13 June. (2114)F

UNIVERSITY OF NOTTINGHAM
SCHOOL OF AGRICULTURE
Food Research

Applications are invited for

TWO RESEARCH STUDENTSHIPS

(1) A CASE studentship to work on protein/polysaccharide interactions in extruded food products.

(2) A MAFF sponsored studentship concerned with the relationship between the viscoelastic behaviour and mouthfeel of modified starch solutions.

The people appointed will form part of a multidisciplinary team working on various aspects of food biopolymers.

Applicants should have or expect to obtain a first or upper second class honours degree in chemistry, food science, physics or biochemistry.

If you are interested, please write to: Dr J R Mitchell, Department of Applied Biochemistry & Food Science, School of Agriculture, University of Nottingham, Sutton Bonington, Loughborough LE12 5RD giving details of academic record and the names of two referees. It would be helpful if you state your preferred research topic. (2111)F

UNIVERSITY OF DUNDEE
DEPARTMENT OF BIOCHEMISTRY

MRC/SERC POSTGRADUATE RESEARCH STUDENTSHIPS FOR OCTOBER 1984

Following an increased number of awards from both the MRC and SERC, the Department invites further applications in one of the following areas from persons who expect to graduate with at least an upper Second Class Honours Degree this Summer.

1. Role of protein phosphorylation in Insulin and Growth factor action; Cloning of protein kinases and protein phosphatases (Dr D G Hardie, Dr P T Cohen, Professor P Cohen).

2. Control of bacterial gene expression at the level of DNA tertiary structure (Dr D J Lilley, Dr C F Higgins).

3. The formate hydrogen lyase system of E Coli (Dr D G Boxer).

4. Characterisation of proteins of the human neutrophil cell surface using monoclonal antibodies (Dr M Kerr).

5. Mitochondrial bioenergetics, mechanisms of theremogenesis in brown fat regulation of calcium transport in synaptosomes (Dr D G Nicholls).

Applications indicating area of interest and containing the names and addresses of three referees should be sent to Professor P Cohen, Dept of Biochemistry, The University, Dundee DD1 4HN, Scotland, as soon as possible.

(2127)F

STUDENTSHIPS

UNIVERSITY OF NOTTINGHAM

DEPARTMENT OF MEDICINE

RESEARCH STUDENTSHIPS

Applications are invited from candidates who have or expect to get a good honours degree in Biochemistry, Pharmacology or a related discipline for studentships, funded for 3 years, which should lead to a PhD The field of study would be concerned with blood platelet behaviour and its relevance to vascular disease.

CV's should be sent to either Professor J R A Mitchell or Dr S Hepinstall at the Department of Medicine, University Hospital, Queen's Medical Centre, Nottingham NG7 2UH. (2091)F

UNIVERSITY OF SOUTHAMPTON

DEPARTMENT OF MICROBIOLOGY

MRC RESEARCH STUDENTSHIP

The work will combine the techniques of molecular genetics and monoclonal antibodies in a study of a chosen human infection. Candidates should hold or expect to obtain a First or Upper Second Class degree in Biochemistry, Microbiology or other relevant subject. Those interested are invited to contact Professor P J Watt on Southampton (0703) 777222 ext. 893.

Applications giving a full curriculum vitae and the names and addresses of 2 referees should be sent to Professor P J Watt, Department of Microbiology, Southampton General Hospital, Hants. SO9 4XY. Please quote Ref: N (2092)F

UNIVERSITY OF ST ANDREWS

DEPARTMENT OF BIOCHEMISTRY AND MICROBIOLOGY

SERC STUDENTSHIP

Applications are invited for a Research Studentship, tenable from 1 October 1984, from those who have, or expect to have, at least 2:1 Honours Degree in Biochemistry or other appropriate discipline. The studentship could be held in one of the following areas of research.

1. The Redox Chemistry and 3-D Arrangement of Electron Components in bacterial membranes.

2. The regulation of eucaryotic gene expression in fungi and higher plants using biochemical and genetic approaches.

3. The mechanism of action of protein and enzymes important in disease processes including neurochemical studies.

4. The molecular biology of adenovirus.

Written applications with full cv the names and addresses of two rees should be sent within two weeks to Dr D Thirkell, Department of Biochemistry and Microbiology, North Street, St Andrews, KY16 9AL tel: 0334 76161 ext 291) to whom further enquiries may be addressed. (2138)F

UNIVERSITY OF LIVERPOOL

DEPARTMENT OF MICROBIOLOGY

TWO RESEARCH STUDENTSHIPS

Applications are invited from candidates who hold, or expect to obtain a First Class or 2i Honours degree for the following studentships:

1. An SERC CASE studentship for three years to work on the relationship between the progress of O-acetylation of Staphylococcus aureus peptidoglycan and β-lactam antibiotics. The student will be based in Liverpool and the academic supervisor will be Professor H R Perkins. A single period of at least three months will be spent working in the Glaxo Greenford Laboratories during the three year course. In addition the student will visit Glaxo not less than twice a year.

2. An SERC studentship for three years to work on one of the following areas: encystment in Azotobacter vinelandii; exoenzyme production by Myxobacteria; physiology of thermophilic bacteria.

Applications together with the names of two academic referees should be sent to The Registrar, The University, PO Box 147, Liverpool, L69 3BX. Quote Ref: RV/525/N. (2117)F

OXFORD UNIVERSITY RESEARCH LABORATORY FOR ARCHAEOLOGY

Carbon-14 dating using a 2 MV tandem accelerator, thermoluminescence dating, archaeomagnetism: studentship(s) for DPhil research, suitable for physicists, chemists, earth scientists, anticipating a good honours degree.

Details: Dr M Aitken or Dr R Hedges, 6 Keble Road, Oxford OX1 3QJ, telephone 55211. (2082)F

THE UNIVERSITY OF LEEDS

DEPARTMENT OF BIOCHEMISTRY

SERC-CASE STUDENTSHIP

Applications are invited for a studentship to study the regulation of plant gene expression by cell wall fragments. The project will involve both structural analysis of bio-active oligosaccharides released from cell walls and a study of the mechanisms through which their release causes alterations in gene expression. The student will be co-supervised by Dr D J Bowles at Leeds and Dr R Selvendran at The AFRC Food Research Institute in Norwich and it is anticipated that the research will involve extended periods of practical work in both institutes.

Applicants should have, or shortly expect to obtain a first or upper second class Honours degree in Biochemistry, Plant Biology or Chemistry.

Informal enquiries may be made to Dr Dianna Bowles (Tel. (0532) 431751 ext. 7506) to whom applications with a curriculum vitae and names and addresses of two referees should be sent. (2087)F

UNIVERSITY OF LONDON
The Medical College of St Bartholomew's Hospital

SERC RESEARCH STUDENTSHIP IN MOLECULAR ENZYMOLOGY

This Studentship is tenable for 3 years from 1st October, 1984 for work on conformational mobility in Enzyme catalytic sites.

Applicants should have, or expect to obtain this summer, a first or upper second class honours degree in Biochemistry or Chemistry and should have an interest in Enzyme reaction mechanism studied by protein modification, stopped-flow kinetics, isotope inventory studies and spectroscopic techniques. Curriculum vitae and the names of two referees should be sent to Dr K Brocklehurst, Department of Biochemistry, Medical College of St. Bartholomew's Hospital, Charterhouse Square, London, EC1M 6BQ, as soon as possible. (2140)F

UNIVERSITY OF BIRMINGHAM

CASE STUDENTSHIP

'The role of the autonomic nervous system in the control of the elasmobranch gut'.

Jointly supervised by Professor J.Z. Young (M.B.A. Plymouth) and Dr. E.W. Taylor.

Applicants must obtain a 1st or 2(i) degree in Zoology or Physiology.

Full c.v. with 2 referees urgently to Dr. E.W. Taylor, Department of Zoology, The University of Birmingham, Birmingham B15 2TT (2079)F

UNIVERSITY OF READING

DEPARTMENT OF PURE & APPLIED ZOOLOGY

NERC (CASE) STUDENTSHIP WITH INSTITUTE OF OCEANOGRAPHIC SCIENCES (IOS)

Quantitative ecology and associated inorganic chemistry of deep benthic Foraminifera.

A three year studentship to study the distribution of deep-sea benthic Foraminifera in the North Atlantic both locally within the sediment and more widely at different bathymetric depths. Shipbased field work will be carried out in conjunction with the IOS where the subsequent faunal analysis will be carried out. Scanning and transmission microscopy and X-ray microanalysis of specimens will be carried out at the University of Reading.

Applicants (who should hold, or expect to gain, an upper second or first class degree in a suitable Biological discipline) should send a cv including the names of 2 referees to Dr A R Jones, Department of Pure & Applied Zoology, University of Reading, Whiteknights, Reading, RG6 2AJ. (2097)F

UNIVERSITY OF ABERDEEN

DEPARTMENT OF PATHOLOGY

SERC CASE STUDENTSHIP

Applications are invited from candidates expecting to obtain or having a first or upper second class honours degree in basic science with a strong immunological component for a SERC CASE STUDENTSHIP leading to a PhD for 3 years from October, 1984. The successful candidate will study some fundmental aspects of the interrelationship between the coagulation system and cell-mediated immune reactions that are of importance in organ graft rejection and rheumatoid arthritis. The work will also involve evaluation of the effects of selected anti-inflammatory agents in disease processes.

The student will be based in Aberdeen but will spend some weeks each year at the Ciba-Geigy Research Centre, Horsham, West Sussex (Dr M K Jasani). Further details may be obtained from the academic supervisor, Dr A W Thomson, Department of Pathology, University of Aberdeen, Medical School, Foresterhill, Aberdeen AB9 2ZD (0224) 681818 extn 2851 to whom a curriculum vitae with the names of two referees should be sent by 14 June 1984. (2077)F

SEMINARS and SYMPOSIA

Topic and Schedule Change

COLD SPRING HARBOR LABORATORY

The **POLYPEPTIDE HORMONES*** meeting, formerly scheduled for August 28 through September 1, 1984 (Organizers J. Feramisco, O. Rosen, R. Ross) is NOW

GROWTH FACTORS AND TRANSFORMATION

September 19-23, 1984

Organizers:
James Feramisco, *Cold Spring Harbor Laboratory*
Brad Ozanne, *University of Texas Health Science Center*
Chuck Stiles, *Dana Farber Cancer Institute*

There will be sessions on Phosphorylation, Oncogenes and Growth Factor Receptor Systems (EGF, TGF, PDGF, lymphokine, and insulin).

* *A **Polypeptide Hormones** Meeting will be held in 1985.*

For registration information please contact:
Meetings Coordinator
Cold Spring Harbor Laboratory
P.O. Box 100
Cold Spring Harbor,
New York 11724

WORKSHOP

EMBO INTERNATIONAL WORKSHOP

The Application of Molecular Biology to the Nervous System

LADY MARGARET HALL, OXFORD **23-25 September 1984**

ORGANISERS: E.A. Barnard, M.R. Hanley, J.F. Jackson
Department of Biochemistry, Imperial College, London SW7 2AZ, UK

TOPICS: Molecular genetic and complementary biochemical and immunological techniques applied to receptors, ion channels, neurotransmitters, neural structural components, and nervous system development

SPEAKERS:
M. Ballivet *(Geneva)*
E. Barnard *(London)*
H. Betz *(Heidelberg)*
J. Brockes *(London)*
J. Changeux *(Paris)*
D. Chikaraishi *(Boston)*
R. Craig *(London)*
C. Gorman *(London)*
R. Greenspan *(Princeton)*
C. Henderson *(Geneva)*
E. Kandel *(New York)*
U. Littauer *(Rehovot)*
J. Mallet *(Paris)*
M. Raff *(London)*
H. Soreq *(Rehovot)*
A. Strosberg *(Paris)*
H. Thoenen *(Martinsried)*
A. Ullrich *(San Francisco)*
C. Venter *(Buffalo)*

The meeting will be a residential workshop limited to 65 participants. Topics will be reviewed by invited speakers and will provide the basis for general discussions. Applications should be sent, with a short statements of recent research, to Professor E.A. Barnard (marking the envelope "EMBO Workshop") before 1 July 1984. A number of places are reserved for postdoctoral workers and limited funds are available for support. The registration fee is £100, payable on acceptance, and will provide full board and accommodation for four nights, conference dinner, and reception.

APPOINTMENTS WANTED

advertise your qualities and qualifications through the most influential science weekly in the world at a special reduced cost of *50 cents a word*. (Personal Box Numbers $10.00).
Advertisements must be pre-paid and sent to: Nature Classified (Appts Wtd), 15 East 26 Street, New York, NY 10010. (890)B

CONFERENCES and COURSES

INSTITUTES OF PSYCHIATRY, NEUROLOGY AND OPHTHALMOLOGY (British Postgraduate Medical Federation, University of London)

This is a ONE-YEAR Course leading to the degree of MSc in Neurochemistry. It offers graduates in science and medicine training in basic and applied neurochemistry. The Course consists of lectures, seminars and laboratory work and, in the second and third terms, research on a neurochemical topic.

Applicants should have a First or Second Class Honours degree in Biochemistry or a cognate subject, or be medically qualified. Application for the Academic Year October 1984-July 1985 should be addressed to the Secretary, Course in Neurochemistry, Department of Biochemistry, Institute of Psychiatry, De Crespigny Park, Denmark Hill, London SE5 8AF. England. (2086)C

UNIVERSITY COLLEGE, LONDON
SCHOOL OF MEDICINE
PART TIME COURSE IN TOXICOLOGY

A course is toxicology consisting of lectures and practical classes will be given weekly for 30 weeks, on Wednesdays at 1600-1900 hours, starting on 26th September 1984.

A broad treatment of topics in toxicology will be presented, including basic histopathology, biochemical and genetic aspects and methodology. Regulatory aspects of toxicology will also be discussed. The course is intended (1) for graduates with some experience in a relevant field; (2) for postdoctoral and other scientists wishing to broaden their knowledge of toxicology.

The fee for the 30 week course is £500. Numbers will be restricted to a maximum of 25 participants. Some assisted places where all or part of the course fees are waived are available to suitable applicants whose fees are not paid by their employer (e.g. persons working in Universities or similar institutions and holding non-tenured posts). Further details and application forms may be obtained from: Dr I C Shaw, Laboratory of Toxicology and Pharmacokinetics, University College London, 5 [illegible] versity Street, London WC1E 6 England. 01-388 2411 ext 276.

Closing date for applications — July 1984. (2144)C

UNIVERSITY OF SURREY
DEPARTMENT OF MICROBIOLOGY
ONE DAY MEETING ON MYCOBACTERIAL INFECTIONS
Wednesday 6th June, 1984.

Innate & Acquired Resistance — Immunodiagnosis — Immunisation — Control.

Speakers: Dr J Stanford, Dr G Rook, Dr L Poulter, Dr C Brown, Dr J Brown, Dr J Colston.

"Ph.D."

The Degree of Difference . . .

That Makes All The Difference in Recruitment Advertising Response

When your organization sets out to recruit highly experienced life scientists, you want to reach employed professionals who are working at the leading universities and corporate research laboratories across the country and around the globe. Typically, these individuals time is so precious that they can only read a limited number of scientific journals.

What better place to concentrate your recruitment advertising than in the world's most respected journal of scientific research . . . Nature enjoys intensive readership among more than 250,000 scientists around the world. By concentrating its editorial at the Ph.D level you are assured of reaching only the top prospects.

Nature's competitive rate structure and fast closing will enable you to lower your cost per hire and fill vital positions weeks quicker than in the past. If you want to reach more Ph.D's advertise in the publication they read more often.

For additional information and a copy of our special issue calendar and the current issue of Nature, please call or write Miss Gene Fein, 15 East 26th Street, New York, NY 10010. (212) 689-5900.

Reduce Contamination Risk!

As a large scale producer of tissue culture cells and currently using roller bottles, you will be aware of the relatively high contamination rate associated with this method.

You can minimize the contamination rate by changing to the Nunc Cell Factory.

The Nunc Cell Factory is a sterile unit designed for the large scale production of cells. During filling and incubation ventilation takes place through a bacteriological filter, which ensures the sterility of the unit.

Compared to roller bottles the number of handlings is drastically reduced, thereby the risk of contamination is minimized.

Additional benefits:

- More efficient utilization of incubator – requires only half the incubator space of roller bottles.
- Cost saving – no capital investment in ancillary equipment.
- Time saving – fewer handlings.

A detailed brochure is available on request – you only have to circle this ad.

ULTRAVIOLET SENSITIVITY IN A MOLLUSC

How to get custom DNA or peptides from a telephone—*Fast!*

Call Biosearch.

Our business *is* synthetic DNA and peptide chemistry. And we've automated these chemistries to supply you with high quality, custom oligonucleotides and peptides for prices that will fit your budget and need for fast delivery.

Custom DNA—Choose from three new pricing options to suit your budget and requirements for speedy delivery. For example, save up to 25% on our regular price if you sequence your custom nucleotide. And fast? Depending on the option you choose,

we can deliver a custom product within **ten days!**

Custom peptides—We guarantee confidentiality, sequence integrity, on-time delivery, and high purity at very competitive prices. Each peptide is shipped with complete analytical data for product verification. Call us with the sequence you need and we'll furnish a quote the same day.

Additional discounts are available for multiple orders. So . . . to get the best custom DNA or peptides from a telephone,
call Biosearch. Today!

DESIGNED FOR A MAJOR ADVANCE IN PEPTIDE SYNTHESIS

THE CRB PEPSYNTHESISER

The first peptide synthesiser incorporating the simplicity and high efficiency of the 'Fmoc-POLYAMIDE' solid phase method with the speed, economy and ease of operation of a CONTINUOUS FLOW SYSTEM.

- Low cost
- Exceptionally mild reaction conditions
- High product yield
- Simple, rapid procedure
- Continuous UV monitoring of reaction progress
- High product purity

The Fmoc-Polyamide Method as developed by Dr. R.C. Sheppard and his group replaces the customary polystyrene resin with a polar polyamide resin. This resin is freely permeated by polar solvents such as dimethylformamide which is a particularly good reaction medium for peptide synthesis. The use of Fmoc amino acids and t-butyl protecting groups avoids the repetitive and vigorous acid treatments required in conventional synthesis and considerably reduces the accumulation of byproducts.

The Continuous Flow System for removal of excess reactants through a column is inherently more efficient than batchwise washing which is used in conventional peptide synthesisers. our continuous flow system has been designed especially for use with 'PEPSYN K'. This polyamide resin is held within the pores of an inert inorganic support which allows the rapid diffusion of reactants without generation of high back pressure.

The Continuous UV Monitoring of both the amino acid addition and the deprotection steps provides reassuring evidence that the synthesis is proceeding normally.

Pepsyn Reagents are provided as a complete range of high purity products prepared specially to ensure maximum success with the versatile Fmoc-Polyamide method. They include Fmoc amino acids and derivatised resins for the synthesis of free peptides, peptide amides and side chain protected peptides.

Technical Support is based on highly successful and extensive use of the Fmoc-Polyamide method in our own laboratories.

- **—Schematic protocols**
- **—Product specifications**
- **—Ordering information**

Current research confirms that RNA c be used successfully for gene probinç providing greater sensitivity than can achieved with similar DNA probes (se our technical information sheets for re ences). The **Riboprobe**™ gene analys system offers a convenient vector/enz system for the preparation of microgr quantities of high specific activity sing stranded RNA's. These RNA's are suitable for use as probes, as RNA pr cessing substrates, and for other ap- plications where large amounts of hot specific RNA's or enhanced probing sensitivity is required.

The **Riboprobe** system consists of: **1)** highly purified, RNase-free bacteri- ophage SP6 RNA polymerase, **2)** the latest **Riboprobe** system SP6 vectors (pSP64, pSP65) as developed by Mel ton, Krieg, and Green, *et. al.* (see tec nical information sheets for references and **3)** a **Riboprobe** system RNA marker template for use as a positive control.

With the **Riboprobe** system, simply ligate your DNA into one of the **Riboprobe** system plasmids, prepare a recombinant plasmid by standard plasmid propagation and purification techniques, linearize the recombinant plasmid with the appropriate restricti enzyme, add the **Riboprobe** system polymerase with labelled ribonucleo- tides, and incubate the reaction.

The **Riboprobe** system does the rest, is exceedingly efficient and, dependin on conditions, can synthesize up to 10 μg of RNA from 1 μg of plasmid template. **The use of this RNA will improve or replace many importan analytical procedures in molecular biology.**

Promega Biotec

Sensitive It Is. Radioactive It Isn't.

The DNA Detection System From BRL.

Until now, only a radioactive label could provide the sensitivity required for detecting small quantities of DNA. Today—with BRL's new DNA Detection System—*you can visualize even single copy genes without radioactivity.*

What the DNA Detection System is:

Sensitive. Using this enzyme-based system, together with the nonradioactive label biotin-11-dUTP, *you can detect 2 to 5 picograms of DNA.* The key to this extraordinary ability is a polymer of alkaline phosphatase, which provides far greater sensitivity than horseradish peroxidase.

Reliable. *Only BRL provides pretested reagents for making DNA test strips* on your nitrocellulose. Developed beside your filter, test strips act as an internal control, enabling you to monitor each visualization reaction.

Easy to use. All the reagents in the system—biotinylated poly alkaline phosphatase, streptavidin, dyes, biotinylated control DNA and DNA dilution buffer—are prescreened for use together. They are packaged in a convenient plastic container in which the filter can be developed. In addition, BRL's DNA detection experts have compiled a clear, step-by-step instruction manual which is included with the system. Our scientists also can assist you when you call the BRL Tech-Line™.

Flexible. You can label your DNA with biotin-11-dUTP and the nick translation reagents or labeling protocol of your choice. Of course, if you choose to purchase BRL's own Nick Translation Reagent System and our Biotin-11-dUTP, you can be assured of optimal results, because they are completely qualified for use with our companion DNA Detection System.

Rapid and inexpensive. Faster than autoradiography, the DNA Detection System actually costs less to use and requires no expensive equipment.

What the DNA Detection System Isn't:

Radioactive. Used with biotin-11-dUTP, our system has none of the safety, stability and disposal problems associated with radiolabeling for autoradiography.

Ask for our brochure and try BRL's DNA Detection System. You'll like it for what it is—and for what it isn't.

NATURE VOL. 309 31 MAY 1984

COVER

Underwater photograph of the giant clam *Tridacna maxima*. Several thousand eyes lie along the margin of the fleshy lobes or syphons which extend beyond the edge of the animal's shell for maximum exposure to light. The study on page 446 describes the visual system of *Tridacna* and shows that some retinal cells contain receptors that are sensitive to ultraviolet light. (Photo: Dr H.G. de Couet).

GUIDE TO AUTHORS

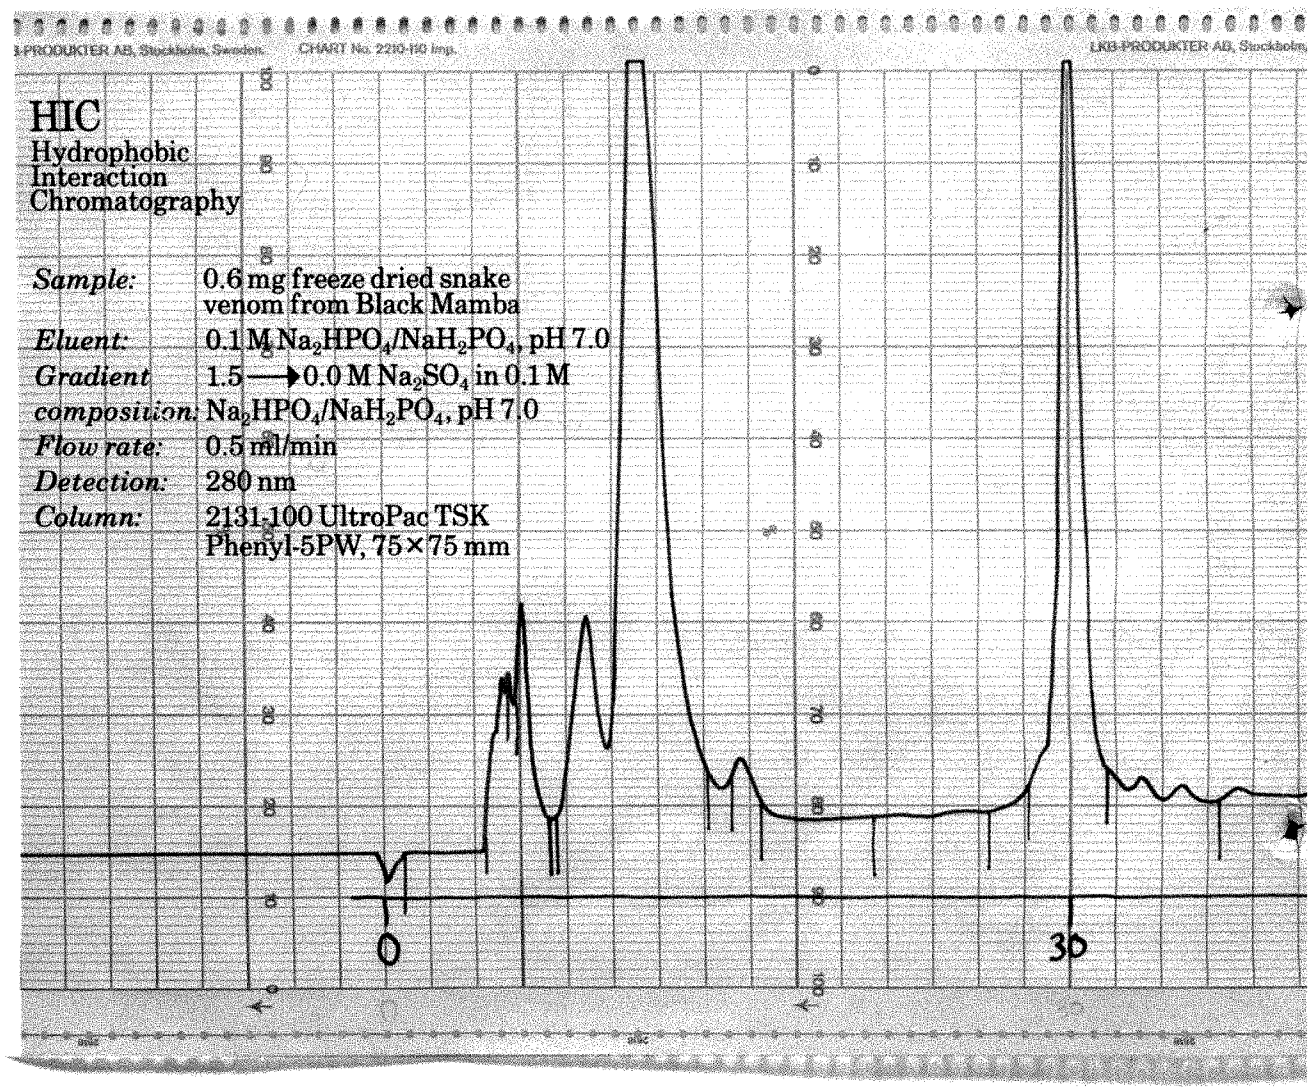
Authors should be aware of the diversity of *Nature*'s readership and should strive to be as widely understood as possible.

Review articles should be accessible to the whole readership. Most are commissioned, but unsolicited reviews are welcome (in which case prior consultation with the office is desirable).

Scientific articles are research reports whose conclusions are of general interest or which represent substantial advances of understanding. The text should not exceed 3,000 words and six displayed items (figures plus tables). The article should include an abstract of about 50 words.

Letters to *Nature* are ordinarily 1,000 words long with no more than four displayed items. The first paragraph (not exceeding 150 words) should say what the letter is about, why the study it reports was undertaken and what the conclusions are.

Matters arising are brief comments (up to 500 words) on articles and letters recently published in *Nature*. The originator of a Matters Arising contribution should initially send his manuscript to the author of the original paper and both parties should, wherever possible, agree on what is to be submitted.



Manuscripts may be submitted either to London or Washington (decisions being made only in London). Manuscripts should be typed (double spacing) on one side of the paper only. Three copies are required, each accompanied by copies of lettered artwork. No title should exceed 80 characters in length. Reference lists, figure legends, etc. should be on separate sheets, all of which should be numbered. Abbreviations, symbols, units, etc. should be identified on one copy of the manuscript at their first appearance.

References should appear sequentially indicated by superscripts in the text and should be abbreviated according to the *World List of Scientific Periodicals*, fourth edition (Butterworth 1963–65). The first and last page numbers of each reference should be cited. References to books should clearly indicate the publisher and the date and place of publication. Unpublished articles should not be formally referred to unless accepted or submitted for publication, but may be mentioned in the text.

Each piece of artwork should be clearly marked with the author's name and the figure number. Original artwork should be unlettered. Suggestions for cover illustrations are welcome. Original artwork (and one copy of the manuscript) will be returned when manuscripts cannot be published.

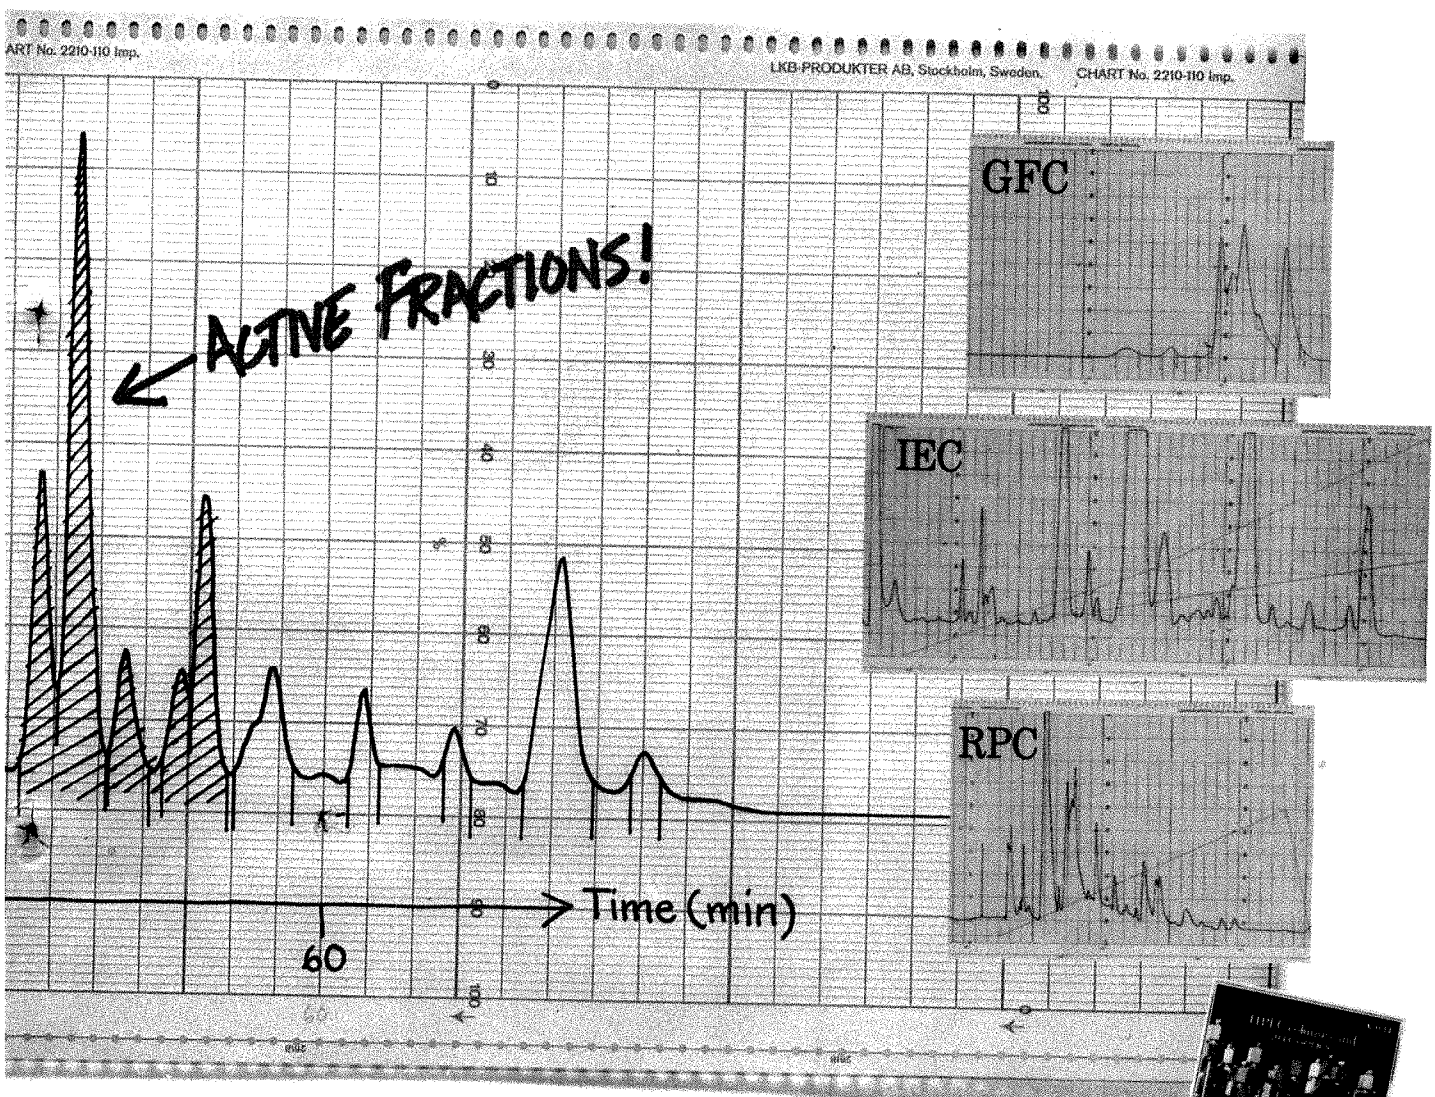
Requests for permission to reproduce material from Nature *should be accompanied by a self-addressed (and, in the case of the United Kingdom and United States, stamped) envelope.*

A new prot
High biological activ

The problem

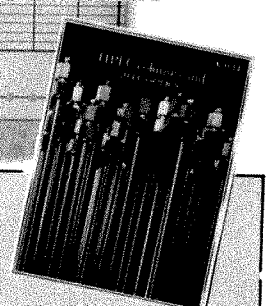
Purification of proteins, peptides and nucleic acids still presents the biochemist with the problem of how to preserve high biological activity, get good resolution, and do it fast.

The answer



A new separation mode – Hydrophobic Interaction Chromatography (HIC)–an aqueous system where *salt gradients* regulate the ability of the column matrix to retain biomacromolecules, *and* keep them active. Control interaction between the hydrophobic sites of a protein with the hydrophobic ligands of your packing material, and you've got the answer – HIC.

The facts



LKB now introduces a new HPLC column that's engineered to meet the special demands of hydrophobic chromatography. The UltroPac® Phenyl-5PW column eliminates all the problems caused by organic solvents provides mild separating conditions and ensures complete accessability even for biomacromolecules up to 10^6. The result is outstandingly high biological activity very fine resolution and fast chromatography.

Whatever your separation method, be it GFC, IEC, RPC and now HIC, LKB's comprehensive range of prepacked columns lets you select the technique most suitable for your sample. A complete choice.

ein HPLC
y with fine resolution

nd you'll find it all in our new catalogue of HPLC olumns and accessories. Get yourself a copy– and get ie facts.

THE KC WIZARD REMOVES THE CURSE OF THE ANTIBODY SNATCHERS.

Significantly increases recoverable monoclonal antibody yields through reduced interference from serum proteins. No more screening of serums for your hybridoma work. No more shifting between serum supplemented medium and serum free media during any of the steps of the hybridoma process.

Now, thanks to the KC Wizard there is a true serum-independent low protein medium developed specifically for hybridoma work that you can use through all phases of hybridoma development and production.

It's the unique KC 2000™, the only true serum-independent medium available today. ALL OTHER SO CALLED SERUM-"FREE" MEDIA REQUIRE SERUM TO WORK IN THE HYBRID DEVELOPMENT PHASES, and it's one medium that really pays off in recoverable monoclonal antibody yields.

KC 2000 offers these distinct advantages:

- It's serum-independent, for better definition, greater reproducibility, and less possibility of contamination by viruses and mycoplasma.
- It's designed specifically for hybridomas, compatible with SP2/Ag 8.653, Ag14, *and* NS-1 cell lines, (See Technical Information Bulletin #24), and works in all phases, including selection and subcloning. KC 2000™ is also compatible with many other cell lines.
- It's formulated and packaged for convenience, well-buffered so you can avoid possible contamination by using closed system incubation and constituted at a 1:9 ratio for easier preparation and less chance for error.

So, don't let those seductive little antibody snatchers reduce your recoverable yields. Discover the *real* serum-independent wizardry of KC Biological! For a copy of Technical Information Bulletin #24 and more information about KC 2000, contact:

Bio-Yeda.

You know our products. Now get to know our name.

The chances are excellent that you've already used some of Bio-Yeda's more than 400 high quality immunochemical and related biotechnological products. They are sold all over the world under names you'd recognize on any reagent shelf. And now, they'll be distributed under our own name as well: Bio-Yeda.

Bio-Yeda's broad scope of products includes:

- □ polyclonal and monoclonal antibodies;
- □ immunoglobulins and IgG subclasses;
- □ antisera to cytoskeletal proteins;
- □ enzyme and fluorescent labeled antibodies;
- □ hormone and drug antisera;
- □ standard and specialized immunodiagnostic agents.

These and similar groups represent more than 400 off-the-shelf Bio-Yeda products—and the list is growing steadily. In addition, Bio-Yeda is prepared to undertake custom preparation of antisera, under our own name—or yours.

Bio-Yeda is an independent subsidiary of Yeda Research & Development company, of the Weizmann Institute of Science, with its own powerful R&D organization.

Bio-Yeda will continue to serve its clients with its full line of diagnostic reagents and research products. The entire Bio-Yeda product range will also be available through a network of Bio-Yeda Distributors in key cities across the globe.

For further information and/or a detailed Bio-Yeda catalog, call your nearest Authorized Bio-Yeda Distributor, or contact Bio-Yeda directly.

For Sensitivity in Prostaglandin Measurement . . . Contact #1— Seragen

Seragen's complete ^{125}I-RIA Kits for:

6-Keto Prostaglandin $F_{1\alpha}$ 100 Tubes

Thromboxane B_2 100 Tubes

offer you:

Convenience— Assay & count in the same tube

Sensitivity— Less than 1pg/0.1 ml sample

Simplicity—Less chance for error

Dependability— Fewer checks & repeats

Seragen is the world leader in measuring prostaglandins with the widest range of ^{3}H-RIA kits, antisera and prostaglandin standards.

For complete technical information or service call toll free **1-800-341-1346**. In Mass. call (617) 265-6004.

INTRODUCING

Centricon™

THE INGENIOUS NEW DISPOSABLE MICROCONCENTRATOR

1. Fast

Pipette your 1-2ml sample into the top reservoir and spin in a centrifuge. That concentrates the sample down to 25-40μl in less than one hour—with no danger of spinning to dryness.

2. Simple

Then invert the top half and spin again briefly. That brings your retentate out where you want it—perfectly accessible in the cone-shaped cup.

3. Efficient

You get high recovery. Desalting or buffer exchange is performed in the sam Centricon simultaneously with concen- tration. And all with no special equipmer no awkward procedures, no cleanup. Centricon is disposable.

Centricon is ideal for concentrating sma biological samples containing proteins, peptides, nucleic acids, viruses, bacteria and other macromolecular solutions. Send for the complete story on this unique new timesaver. Or call Technical Service: 800-343-1397.

Patent Pending

TRANSFER TO VIOLET with ACID PHOSPHATASE

DETEK™ I-*acp*

A preformed streptavidin enzyme complex for visualization of biotinylated DNA
or
biotinylated protein

- 50 fold increase in sensitivity compared with any existing colorimetric enzymatic detection system
- Most sensitive detection complex commercially available
- Visualization within three hours
- A replacement for I^{125} in protein iodination when used in conjunction with N-hydroxy succinimide biotin ester (EAB-406)
- Detek I-*acp* is sold exclusively by Enzo Biochem

Patent Pending

Visualize 1 to 10 picograms of target DNA on Southern transfers and 0.6-1 nanograms of protein on Western blots.

Visualization is 50 fold more sensitive than other enzymatic biotin-avidin systems currently available.

Detek I-*acp* comes complete with the streptavidin acid phosphatase complex, dilution buffer, naphthol AS-MX phosphate and fast violet B salt substrates. It is packaged in two convenient sizes.

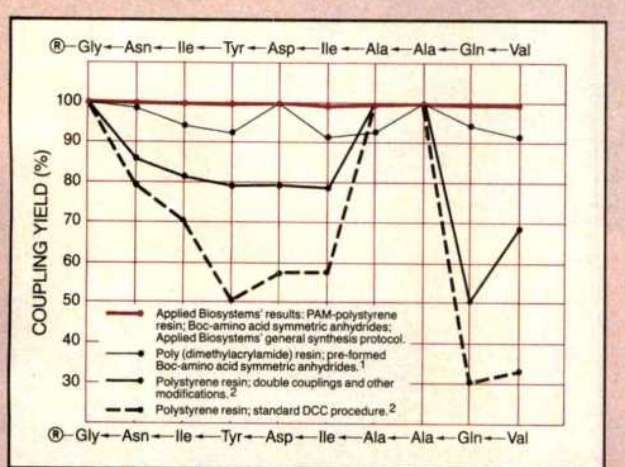
EBP-821-1 Detek I-*acp* $55.00
—Sufficient reagents for 25 Southern or Western blots*

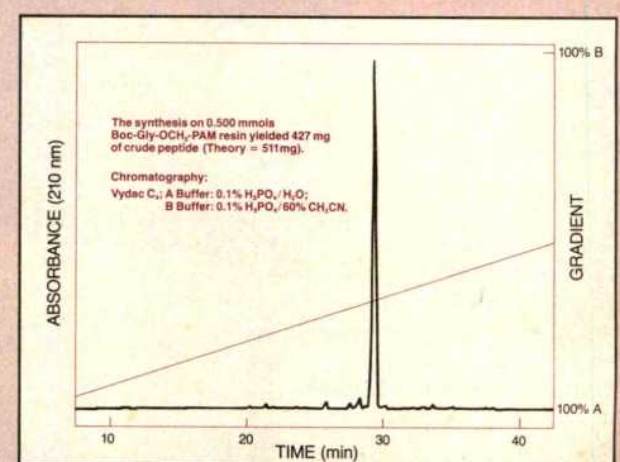
*81 square centimeters each

BIOSYSTEMS UPDATE



A New Approach to Automated Peptide Synthesis

Applied Biosystems is pleased to announce the first instrument designed for high efficiency peptide synthesis. The key to the high coupling yield of the Model 430A Peptide Synthesizer is an activation unit which converts the amino acid to a very efficient acylating species immediately prior to the coupling step. The defined protocol has been optimized for general peptide synthesis, but the fully programmable system allows straightforward adaptation to other chemistries.



Cycle times with the general synthesis protocol are approximately one hour. A single loading of protected amino acids, reagents, and solvents will give up to 50 synthesis cycles. To insure high coupling yields, Applied Biosystems manufactures and supplies all synthesis reagents.

The data below summarize the results of the synthesis of the decapeptide Acyl Carrier Protein (65-74). These results illustrate the combined capabilities of the novel automated synthesis procedure and the high quality peptide synthesis reagents and loaded resins.

The new Model 430A Peptide Synthesizer was introduced at FASEB and Analytica, and will be exhibited at the ASBC Meeting. For more information, circle No. 08

Amino acid incorporation during assembly of Acyl Carrier Protein residues 65-74.

HPLC chromatogram of crude, HF cleaved Acyl Carrier Protein (65-74).

ANALYTICAL METHOD	STEP YIELD (%)									
Quantitative Ninhydrin Monitoring[3].	—	99.9	99.6	99.5	99.4	99.1	99.2	99.2	99.1	98.9
Preview Quantitation by Solid Phase Sequencing of Protected, Resin Bound Peptide[4].	—	—	99.4	—	99.3	99.1	99.2	—	98.9	98.7
	RELATIVE AMINO ACID EQUIVALENTS									
Amino Acid Analysis of HF Cleaved, Deprotected Peptide	1.00	0.97	0.90	0.94	0.97	0.90	0.96	0.96	0.94	0.98
Amino Acid Residue	Gly	Asn	Ile	Tyr	Asp	Ile	Ala	Ala	Gln	Val

Step yield quantitation and amino acid analysis results for Acyl Carrier Protein (65-74) chain assembly using Applied Biosystems' general synthesis protocol. Only single couplings were used throughout the synthesis (except for Gln).

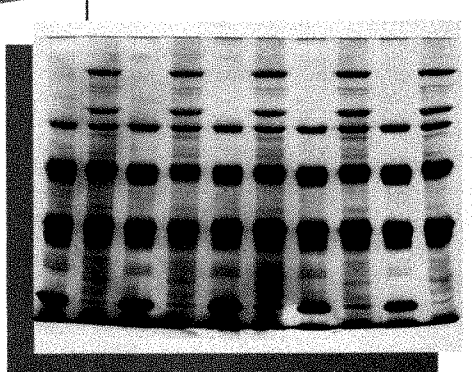
FAST TOTAL ANALYSIS

Bio-Rad's Mini-Gel systems combine quality apparatus and reagent kits with tested protocols to provide *complete* electrophoretic analyses with unprecedented speed. And equally important, with no sacrifice of resolution. Here are a few examples that illustrate the dramatic improvement possible with our systems approach:

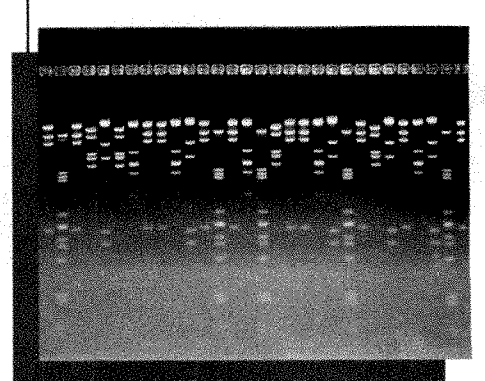
Bio-Rad Mini Gel Systems can save you hours of protein and DNA analysis time.

WIDE MINI-SUB DNA CELL. The only miniature submarine cell with 30 to 60 sample capacity. Hours faster than conventional equipment for screening applications.



MINI VERTICAL SLAB CELL. Separations in only 45 minutes! Rapid performance is made possible by a unique glass/alumina sandwich, which transfers heat 40X more efficiently than glass.

■ A complete SDS-PAGE/silver stain analysis in only *2.5 hours*. The system includes Bio-Rad's new Mini-Vertical Slab Cell, which analyzes proteins and nucleic acids two to three times faster than conventional 16 cm cells, and our easy-to-use Silver Stain Kit.



■ Rapid screening of restriction digests using the only available miniature sub-cell with 30-sample capacity. This new Wide Mini-Sub™ DNA Cell can separate 30 samples in anywhere from 10 minutes to 2 hours, as compared to 4 to 12 hours with conventional equipment.

■ Electrophoretic separation, high intensity electrophoretic transfer and detection of proteins—all in *one day* using the Mini-Vertical Cell, our Trans-Blot® Cell, and our new Immun-Blot™ Kit. The latter provides all of the necessary components for rapid, sensitive detection of membrane bound monoclonal and polyclonal immune complexes.

To help you obtain excellent results consistently, we have put a lot of thought and work into our protocols. But we don't stop there. An experienced technical staff stands behind every Mini-Gel system, ready to help you achieve the best possible analyses in the shortest possible time.

ALTERNATING high and low MW standard on 0.75mm gel. Total run time 45 minutes on the Mini Vertical Slab Cell. Silver stained with the Bio-Rad Silver Stain Kit.

30 SAMPLES OF DNA restriction digest analyzed with Wide Mini-Sub Cell using Bio-Rad Ultra Pure DNA Grade Agarose.

Frontiers in Biomedical Research Has Arrived!

Announcing an exciting publishing event in the field of biomedical research.

A new catalog that's much more than a catalog from Pel-Freez.

The future is arriving at breakneck speed. Cell fusion, genetic engineering, molecular biology are expanding the frontiers of biomedical research at an exponential rate.

For over thirty years, we at Pel-Freez have shared a commitment to the future with biomedical researchers across the country. That's why we are extremely proud to announce the publication of our new catalog—*Frontiers in Biomedical Research.*

Exciting, unique format—easy to read, easy to use.

To meet the challenge of the future, you often need more than just a listing of products. You need a product's origin or species, processing technique and even in some cases, how to use it most effectively. You get all this in *Frontiers in Biomedical Research*—and all at your fingertips. No more cross-referencing or time-consuming phone calls.

Over 2,000 important products for today's researcher.

Frontiers in Biomedical Research contains comprehensive, up-to-date information on monoclonal antibodies, affinity-purified antibodies including soluble complexes and mouse-host antisera, custom antisera service, purified proteins, rabbit complement and HLA products, and animal bloods and tissues.

Pel-Freez makes major commitments to immunology.

Our job is to deliver the products and up-to-the-minute information you need to do your job. *Frontiers in Biomedical Research* contains a significant number of new products representing additional major commitments to the field of immunology: a complete line of monoclonal antibody detection and screening agents, PAP and GAG soluble complexes and an expanded line of conjugated immunochemical products. Also histocompatibility and rabbit complement products.

A resource you can count on from an established source you've come to trust.

Frontiers in Biomedical Research is not like any catalog you've ever seen or used. In the hands of a competent biomedical researcher, it is an invaluable resource that delivers a complete and current line of biomedical products.

Our thirty years of customer service have taught us a few good lessons. Convenience, consistency, reliability—they're all here in *Frontiers in Biomedical Research.*

Order your free copy today!

Why wait?

Use our toll-free number and your copy will be in the mail today.

Selectively Immobilize *m*RNA from Whole Cells–in Hours, Not Days–With the New S&S Quick-Blot™ Kit

Selective immobilization of multiple samples of *m*RNA onto nitrocellulose—in hours—can now be achieved with the S&S Quick-Blot Kit, using dot-blotting techniques and the S&S Minifold®, a 96-well microsample filtration manifold. The Quick-Blot system, for simple, rapid and efficient immobilization of *m*RNA from either whole cells or viruses, is highly selective because *only* *m*RNA binds to the NC. Because no baking is required, the *m*RNA remains biologically active and is easily translated, reverse-transcribed, hybridized or released and manipulated.

Each Quick-Blot Kit includes enough *m*RNC™ nitrocellulose, reagents and NaI-Plus™ solution for 120 samples. S&S NaI-Plus is a proprietary 'reagent grade' sodium iodide solution developed by S&S to optimize the selective immobilization of *m*RNA onto *m*RNC in the Quick-Blot technique.

New and recent titles from Academic Press...

THE RETINOIDS
Volumes 1 and 2

Edited by MICHAEL B. SPORN, ANITA B. ROBERTS, and DEWITT S. GOODMAN

Volume 1

CONTENTS: Introduction. Chemistry and Physical Properties of Retinoids. Synthesis of Retinoids Labeled with Radioisotopes. Extraction, Separation, and Chemical Analysis of Retinoids. Biological Methods of Analysis and Assay of Retinoids—Relationships between Structure and Activity. Vitamin A in Animal and Human Nutrition. Appendix. Each chapter includes references. Index.

1984, 448 pp., $46.00*/£35.00 (U.K. only)
ISBN: 0-12-658101-0

Volume 2

CONTENTS: Biosynthesis, Absorption, and Hepatic Metabolism of Retinol. Plasma Retinol-Binding Proteins. Cellular Retinol-Binding Proteins. Retinoids in Photosensitive Systems. Metabolism of Retinoids. Cellular Biology and Biochemistry of the Retinoids. Preclinical and Clinical Toxicology of Selected Retinoids. Retinoids and Cancer. Retinoids and the Immune System: Immunostimulation by Vitamin A. Synthetic Retinoids in Dermatology. Appendix. Each chapter includes references. Index.

1984, 464 pp., $48.00*/£37.00 (U.K. only)
ISBN: 0-12-658102-9

***Set price for Volumes 1 and 2: $80.00/£52.50 (U.K. only) ($94.00/£72.50 (U.K. only), if purchased separately). Set prices are not valid in Australia or New Zealand.**

ELECTRON MICROSCOPY OF PROTEINS
Macromolecular Structure and Function
Volume 4

Edited by J. R. HARRIS

CONTENTS: *E. J. O'Brien and M. J. Dickens*, Actin and Thin Filaments. *R. Craig and P. Knight*, Myosin Molecules, Thick Filaments and the Actin-Myosin Complex. *D. M. Shotton*, The Proteins of the Erythrocyte Membrane. *C. A. L. S. Colaco and W. H. Evans*, Plasma Membrane Intercellular Junctions. Morphology and Protein Composition. Subject Index.

1984, 388 pp., $65.00/£39.00 (U.K. only)
ISBN: 0-12-327604-7

PLASMA PROTEIN SECRETION BY THE LIVER
Edited by HANS GLAUMANN, T. PETERS, and C. REDMAN

CONTENTS (Section Headings): Methods. Interpretations. Synthesis and Secretion of Specific Proteins. Applications.

1983, 512 pp., $75.00/£46.00 (U.K. only)
ISBN: 0-12-286180-9

ELECTROPHORETIC TECHNIQUES
Edited by COLIN F. SIMPSON and MARY WHITTAKER

CONTENTS: Basic Theory of Electrophoresis: Definitions, Terminology and Comparison of the Basic Techniques. Electrophoretic Methods for Molecular Characterization of Proteins. Recent Developments in Isoelectric Focusing. Analytical Isoelectric Focusing on Cellulose Acetate Membranes and Agarose Thin Layers. Ultra-Thin-Layer Isoelectric Focusing. Gel Immunoelectrophoresis. Analytical Isotachophoresis. Preparative Isotachophoresis. Preparative Displacement Electrophoresis. Preparative Isoelectric Focusing. Free-Flow Electrophoresis. Subject Index.

1983, 292 pp., $44.00/£27.00 (U.K. only)
ISBN: 0-12-644480-3

BACTERIAL VACCINES
Edited by P. GERMANIER

TENTATIVE CONTENTS: Diphtheria. Tetanus. Pertussis. Cholera. Typhoid Fever. Shigellosis. *Escherichia coli* Infections. Meningococcal Meningitis. Pneumococcal Infections. *Haemophilus influenzae* Type b Infections. *Pseudomonas aeruginosa* Infections. Gonorrhea. Tuberculosis. Leprosy. Index.

TWO-DIMENSIONAL GEL ELECTROPHORESIS OF PROTEINS
METHODS AND APPLICATIONS

Edited by JULIO E. CELIS and RODRIGO BRAVO

This timely volume on two-dimensional gel electrophoresis of proteins presents a compilation of current procedures and research in which this technique is being applied. The authors unite improvements in the methods for detecting, quantitating, comparing, characterizing, and storing information contained in the gels with a step-by-step guide to the techniques so that procedures may be easily repeated.

CONTENTS (Section Headings): Methods and Satellite Techniques. Applications of Two-Dimensional Gel Electrophoresis. Protein Catalogs.

1984, 504 pp., $69.50/£54.00 (U.K. only)
ISBN: 0-12-164720-X

NEW! Manual DNA Synthesis Kit

- Easy-to-use
- High speed chemistry
- Makes up to *four* 20-mers
- Inexpensive

Catalog number: NU-6092

The Biosearch Kit utilizes a modified phosphate-triester synthesis method that features 20 minute cycle times and excellent reagent stability! Short cycle times make this kit less tiring to use than other kits and enables the user to make more than one oligomer in a day. The kit contains a supply of reagents sufficient to synthesize four 20-mers, a complete set of instructions, a description of the chemistry, and purification and characterization techniques.

If you hate waiting you'll love ENLIGHTNING™

The new one-step fluorography enhancer that's ten times faster than PPO-DMSO.

ENLIGHTNING™ Rapid Autoradiography Enhancer takes only 15 to 30 minutes to process your gels, compared to five hours for PPO-DMSO.

And in only one step: simply soak the gels in ENLIGHTNING™. No multi-step procedure. Quick processing minimizes diffusion artifacts and loss of smaller molecular weight components, too.

The resulting fluorograms are fully comparable to those obtained using other fluorographic techniques, with either polyacrylamide or 2% agarose gels (3mm min. thickness).

And easier to live with in the lab.

ENLIGHTNING™ is odorless and safer to work with than enhancers containing DMSO. It requires nothing more than standard laboratory gloves. What's more, refrigeration is unnecessary; ENLIGHTNING™ has a long shelf life at room temperature.

THE LIFE OF SCIENCE

COSTA RICAN NATURAL HISTORY
Edited by **Daniel H. Janzen**
A landmark publication in tropical biology with worldwide applications, this splendidly illustrated volume combines the expert knowledge of 174 contributors. It offers detailed discussions of agricultural species, vegetation, reptiles and amphibians, mammals, birds and insects; and detailed species accounts of more than 300 of the most important, interesting, or conspicuous organisms.
832 pp. 306 halftones, 54 line drawings.
£42.50 cl., £25.50 pa.

FORM AND FUNCTION: *A Contribution to the History of Animal Morphology*
E.S. Russell
With a New Introduction by **George V. Lauder**
First published in 1916, this classic history of functional morphology from Aristotle through the nineteenth century is still relevant to current lines of investigation. "Russell's book is simply a brilliant synthesis... a magnificent history of science." —Keith S. Thomson, Yale University
£9.30 pa.

DARWIN AND HIS CRITICS:
The Reception of Darwin's Theory of Evolution by the Scientific Community
David L. Hull
In this case study of the publication, dissemination, and acceptance of a scientific theory in the 19th century, Hull presents fifteen contemporary reviews of the *Origin*, with comments by Darwin and historical notes on each review. "A learned and deeply reasoned book." —P.B. Medawar, *The New York Review of Books* £12.75 pa.

PRINCES AND PEASANTS: *Smallpox in History*
Donald R. Hopkins
Hopkins traces the devastating effects of smallpox on the great and the lowly alike, showing how the blind chance of the disease repeatedly changed the course of history. "With admirable boldness Hopkins has written an encyclopedic account... he has done a superb job of organizing his material." —*Natural History*
Illus. £21.25 cl.

WORKERS AT RISK: *Voices from the Workplace*
Dorothy Nelkin and Michael S. Brown
This arresting study of the physical and psychological hazards of working with chemicals is based on interviews with dozens of workers who speak compellingly of their perceptions, worries, and concerns about exposure to chemicals. The authors argue that such objective data must be taken into account in risk assessment. £17.00 cl.

The first English translation of an acclaimed Russian work

RELATIVISTIC ASTROPHYSICS
Ya. B. Zel'dovich and I.D. Novikov
Volume I: Stars and Relativity
Edited by **Kip Thorne** and **W. David Arnett,**
Translated by **Eli Arlock**
Volume II: The Structure and Evolution of the Universe
Edited by **Gary Steigman,** Translated by **Leslie Fishbone**
Together these two volumes describe the fundamental processes and types of phenomena relevant to relativistic astrophysics and provide a remarkably complete picture of the present state of cosmology. "This eagerly awaited first English version... fully lives up to expectations.... Undoubtedly this will become a fundamental reference text and source for teaching." —J. Richard Gribbin, *Nature*
Volume I: 522 pp. £34.00 cl.
Volume II: 768 pp. £55.25 cl.

PRINCIPLES OF STELLAR EVOLUTION AND NUCLEOSYNTHESIS *With a New Preface*
Donald D. Clayton
A popular text for graduate students in astronomy and astrophysics since its publication in 1968, this book has been updated by the author's Preface to cover the most original research carried out since then. 612 pp.
£27.20 cl., £12.75 pa.

THE LOGIC OF DECISION *Second Edition*
Richard C. Jeffrey
In this new edition of his now classic 1965 work, the author adds, among other features, new exercises and notes and references at the ends of most chapters. "Here is a book written at a relatively elementary level... which not only lays out an up-to-date outline of the subjectivist theory of probability, utility, and choice, but makes significant advances in that theory." —*Philosophical Review*
£17.00 cl.

THE ATOM BOMB AND THE FUTURE OF MAN
Karl Jaspers
The distinguished psychiatrist/philosopher argues that there is a possibility that the fear of nuclear warfare will so pervade human consciousness that a new moral force will produce a politics adequate to handle the threat.
£8.45 pa.

FPLC from goes beyond HPLC

Also in biochemistry you want your first results in 10 minutes, a lot of results in a day, and a breakthrough in a week with the high speed and resolution of high performance liquid chromatography (HPLC). In addition you need biocompatibility when separating and purifying labile biomolecules to preserve biological activity and obtain high yields.

The Pharmacia FPLC* system goes beyond HPLC with biocompatible instruments and unique columns of new media designed for high performance

- Enzyme purifications
- Peptide mapping
- Analytical protein separations
- Purification of biologically active peptides
- Separation of oligo- and polynucleotides

The FPLC columns can be repeatedly cleaned, with maintained performance, significantly extending their lifetime. Of course you can also run your traditional columns of Sephadex®, Sepharose®, etc. on your FPLC system.

Pharmacia's experience of 25 years as the leader in biochemical separation techniques is now available to help you discover the full capabilities of high performance chromatography of biomolecules in your laboratory.

COLD SPRING HARBOR LABORATORY ANNOUNCES

Molecular Cloning

A Laboratory Manual

By T. Maniatis, *Harvard University*
E. F. Fritsch, *Michigan State University*
J. Sambrook, *Cold Spring Harbor Laboratory*

This comprehensive up-to-date manual contains a description of the principles of molecular cloning and detailed protocols for all the fundamental techniques currently in use. Numerous illustrations, a complete bibliography and a detailed index enhance the usefulness and accessibility of the material presented. Designed for use at the "lab bench," this manual should prove valuable for both established investigators and students who need to utilize molecular cloning techniques.

Paperback $40 ($48 outside US)

Volume 3

GENETIC MAPS / 1984

A Compilation of Linkage and Restriction Maps of Genetically Studied Organisms
Edited by S. J. O'Brien, *Laboratory of Viral Carcinogenesis, National Cancer Institute*

Completely updated and expanded, this 1984 edition of GENETIC MAPS contains 85 maps and covers 75 organisms. It includes linkage maps of all genetically studied organisms as well as restriction maps of the major bacterial and animal viruses, including lambda, T4, adenoviruses, SV40 and all retroviruses.

The only collection of its kind, GENETIC MAPS is an indispensible handbook for anyone involved in genetics whether researcher or student.

June 1984, 500 pp. (approx.), illus.
ISBN 0-87969-171-9
ISSN 0738-5269
Prepublication price (Paper) $25 ($30 outside US)

Experiments with Gene Fusions

Edited by T. J. Silhavy and M. L. Berman, *NCI-Frederick Cancer Research Facility*
L. W. Enquist, *Molecular Genetics, Inc.*

For research scientists, teachers and student, this instructionally complete and scientifically tested manual brings together gene fusion and recombinant DNA methods with more classical genetic techniques and demonstrates the power and utility of using these combined approaches for the analysis of an experimental system.

May 1984, 304 pp., appendixes, biblio., index
ISBN 0-87969-163-8

Paperback $40 ($48 outside US)

Recombinant DNA Applications to Human Disease

Edited by C. T. Caskey, *Baylor College of Medicine*
R. L. White, *University of Utah School of Medicine*

Applications of recombinant DNA methodologies to the human genome is providing new opportunities for analyzing the actions of specific genes in health and disease, determining physical linkage relationships of known and unknown disease loci, elucidating human chromosomal organization, and formulating new approaches in management of heritable disorders. The book includes the presentations and discussions emanating from the conference held at the Banbury Center on this subject.

Superior technology that works for you

Built-in automation facilitates rapid execution

The NEW VANOX-S microscope will revolutionize the way you think about microscopes. The VANOX-S, with its built-in computer handles tedious chores, freeing you to do the really important work. Condenser choice, brightness adjustment, adjustment of aperture and field diaphragms are fully automatic—an advancement in efficiency resulting from the Olympus "built-in" concept. Thus, annoying, time-consuming operations are reduced to nothing more than the touch of a button on the control panel. From observation to photography, operation is simple, fast and accurate—a result of Olympus's total dedication to the most advanced technology.

- Automatic selection of built-in condensers for Koehler-system illumination for 1× to 100× (objective magnification)
- Manual and automatic operation
- Attachments for three cameras (two 35mm cameras & one large format camera)
- Built-in auto-exposure function
- Choice of integrated or spot metering
- 4 built-in photographic eyepieces and light balancing filters
- Special viewfinder lets you see what you are photographing
- Attachments for various microscopic methods

The way ahead...

British Journal of Pharmacology

Published monthly on behalf of the British Pharmacological Society, the British Journal of Pharmacology contains original papers submitted from all parts of the world making it one of the most respected journals for all those professionally involved in the pharmacological sciences. It contains up-to-date papers of the highest quality on all aspects of drug action and is thus a vital source of information for physiologists, clinicians, immunologists, molecular biologists and biochemists as well as pharmacologists.

Subscription Prices
UK £145.00, USA/Canada US $360.00 surface, US $440 airmail,
Rest of World £160.00 surface, £210.00 airmail.

HUMAN TOXICOLOGY
An International Journal

Published bi-monthly this new journal features the following material:

* original papers of a high scientific standard on all aspects of human toxicology, embracing both animal research and studies with humans
* short communications
* invited comment on current matters of professional interest
* editorials on topical issues
* review papers
* book reviews

Subscription Prices
UK £65.00,

Rest of World
£75.00 surface,
£95.00 airmail.

Pharmaceutical Medicine

New For 1984...

A new, independent, quarterly journal for the critical assessment of new and old methods employed to test drugs in man. To promote the discipline of pharmaceutical medicine and cover those activities germane to human testing of drugs, papers will appear on human pharmacology, clinical investigation, comparative clinical trials, and epidemiological studies. The latter will inevitably be associated with drug safety and post-marketing surveillance. The problems of quality control and analysis of laboratory tests will be addressed, and the handling of clinical trial data. The design and statistical analysis of clinical studies will also feature.

Pharmaceutical Medicine will provide invited contributions, reviews, news and opinion. A major feature will be abstracts of papers published elsewhere giving new means of assessing drugs.

The Journal will not take an overtly political or commercial position, but any matters affecting ways and means of assessing drug efficacy and safety, including governmental regulations, will be discussed.

Subscription Rates
UK and Eire: £45.00, USA/Canada: Surface US $95.00, Rest of World: Surface £63.00

British Journal of Anaesthesia

The British Journal of Anaesthesia has consistently been the leading independent journal in anaesthesia enjoying international contributions and readership.

Published monthly the journal offers:

* Sections on laboratory investigation, clinical research, case reports and information on apparatus.
* A correspondence section in which views are exchanged through short communications and comments on matters of professional interest.
* Book Reviews.
* Postgraduate Educational Issues, on both clinical and basic themes, produced twice a year – indispensable to established clinician and trainee alike.

Subscription Prices UK £38.50, USA/Canada US $90.00,
Rest of World £53.00 surface, £95.00 airmail,
Trainee rates UK £24.00, US $50.00.

The British Journal of Cancer

Published monthly on behalf of the Cancer Research Campaign, The British Journal of Cancer is one of the leading cancer journals in the world, publishing articles in all the major scientific disciplines relevant to the subject. The journal provides papers and short communications submitted by scientists from countries throughout the world. In addition, the Proceedings of the meetings of the British Association for Cancer Research are regularly published in the journal. From time to time other selected national and international meetings are also covered. Up-to-date book reviews appear in each issue.

Subscription Prices
UK £99.00, USA/Canada US $240.00 surface,
US $285.00 airmail,
Rest of World £124.00 surface,
£160.00 airmail.

Isolate DNA and RNA with CsTFA™ a new centrifugation medium

- Convenient isolation of nucleic acids
- Improves purity and quality
- Bands all types of RNA
- Inhibits nuclease activity
- Fewer phenol extractions
- Easy recovery by ethanol precipitation
- EtBr-free one-step plasmid isolation

Contact us today for more information on CsTFA and other high quality centrifugation media for nucleic acids, including optical and reagent grades of CsCl, or order directly from your local representative.

Handling the human embryo

Proposals for the organization of British practice are a useful curtain-raiser for the government's own report. But physicians should regulate themselves before the government steps in.

THE Council for Science and Society has usefully stolen a march on the British Government by publishing (last week) the report of a study of new techniques of conception, some old (such as artificial insemination), some futuristic (such as cloning). The document (*Human Procreation*, OUP, £3.95) has been put together by a committee under Dr G.R. Dunstan, an academic Anglican with at least fifteen years' experience of these problems, but with a good sprinkling of hard and level-headed biologists to help tell one end of a blastocyst from another. The document appears some three months before the report of the official committee under Mrs Mary Warnock is due to report. Being a liberal and even modestly adventurous tract — Dunstan would allow the use of fertilized but unimplanted embryos for research, is neutral on surrogate motherhood (saying that it should neither be encouraged nor made unlawful) and sternly dismissive on the choice of the gender of unborn children. In all probability, this is where the Warnock committee will stand. Certainly that committee's recommendations on the legal framework for embryonic manipulation cannot be less liberal without seeming unhelpful.

The Dunstan document is said to have been designed to be thought-provoking, which mostly it is. But on some issues the group seems to have decided that a dash of pragmatism is the only sensible way of avoiding arguments that can never be settled. Thus the committee dodges the question of when life can be said to have "begun" by argument by analogy with the law on abortion in the United Kingdom. Sperms and ova are alive, so "life" must mean something else, but development is continuous after fertilization so why not extend the limiting age of a fetus for legal abortions to other practices now possible for the first time, the study of development in viable embryos, for example? The trouble, as the Dunstan committee must know, is that there is a substantial body of opinion in Britain opposed to that limit, and eager to see the Abortion Act repealed. If the Warnock committee makes recommendations along the same lines (which it should), there is certain to be a revival of agitation against the rules on abortion.

Privacy is dealt with more robustly. The issue arises in connection with existing practices such as artificial insemination (estimated at 4,000 cases a year, not much greater than in the early 1970s) but, more generally, whenever a child is born with genes not all derived from its social parents. On the question whether such a child should at some stage be told something of the source of the genes, the Dunstan committee is for "openness within the family", which would imply that a child would eventually have a right to know as much about, say, the donor of semen as the parents themselves were told at the outset. But the committee would protect the confidentiality of the donor, largely because it fears that the supply of donors would otherwise dry up but also because it holds that a child's relationship with its social parents should not be prejudiced by the intervention of a third party, either a semen donor or a surrogate mother. The view is consistent. The obvious difficulty is that responsibility for keeping genetic records of these shadowy but essential third parties will rest with physicians whose practices are already shadowy enough. But especially in Britain, where the Data Protection Bill will do very little to strengthen the privacy of individuals in relation to the state, it would be too dangerous to ask for a centralized data bank of the genetic parents of other people's children. Is there a case for physicians' professional associations shouldering this task?

The committee's weakest conclusion is that it would not be permissible to allow parents to choose the gender of their children. Technically, this can already be done by amniocentesis and abortion, but an unwelcome gender is not a legal ground for abortion. Soon, easier ways of doing this job will be available. The starting point for much of Dunstan's argument is that, if stable couples are prevented by some disability from procreating naturally, they should be helped by whatever techniques are available to produce children in some other way. Why draw the line at gender-rigging? A farming family of a dozen daughters and no sons may be as seriously handicapped as one that is infertile. So why not acknowledge that physicians should be encouraged to offer even such a service if there are strong grounds for believing that the results would be socially beneficial?

With its pragmatic view of the problems of embryo manipulaton, the Dunstan committee inevitably is less concerned with the legal than the administrative changes of the framework in which the physicians deal with their patients. (But it would change the law to protect donors of sperm from paternity suits.) Writing for a British audience, it asks that the National Health Service should take responsibility for providing whatever services are available, that donors (of anything) should not be paid for their services and that there should be more provision for counselling than at present. The committee looks enviously across the English Channel at the centralized service by means of which the French health services arrange for sperm donors to be married couples with at least one healthy child. The committee acknowledges that there are problems with surrogate mothers (who would not act as hostesses without reward of any kind) but seriously underestimates the difficulties of ensuring that all services like these can somehow be swept up into the public sector. That is why there can in the long run be no escape from a system in which individual practitioners offering services as different as artificial insemination and sex determination should be registered (even licensed) by their professional associations and should contribute data about their practice to some confidential data bank run by the same association. That, it is to be hoped, is what Warnock will say. □

Liberation language

THE introduction to the Dunstan report by Professor John Ziman, who quotes from Dante's *Purgatorio* a definition of life as

. . .one
quick, sentient soul, of its own self-aware,

includes the following explanation of a now-unfashionable useage:

The report is written in English, a language which has a common gender for statements applying to masculine and feminine, male and female, without distinction. Sometimes the grammatical form of the common gender and masculine coincide, but that is no impediment to its use. We have employed this grammatical facility because it yields a prose less cluttered and more elegant, and as readable. □

Small beer, no skittles

The British research system needs to spend more on research grants, less on machines.

UNWITTINGLY, the British Science and Engineering Research Council (SERC) has given a telling explanation of why the United Kingdom is considering withdrawal from the European high-energy physics laboratory, CERN, at Geneva. The council's science board, the chief source of research grants for British academics whose interests are not bound up with space, astronomy and high-energy physics, last week published a statement of what it calls its strategy for "core science" — what is left when the great machine-created baronies have been catered for (see *Nature* **309**, 297; 1984).

The results are shocking. The board spends just over £70 million a year, which is divided into three roughly equal parts, one of which goes to keep the bodies and souls of graduate students and doctoral fellows in some loose correspondence, another on the running of central facilities (such as synchrotron and laser sources) and a third, roughly £25 million a year, on research grants to working scientists in all disciplines. Having proudly calculated that 12,000 people are dependent on it for research money, it omits the simple arithmetical calculation that there is less than £2,000 a year for each person on its books.

Lopsidedness also leaps out from this eight-page glossy production. University research in physics, for example, costs the board between £5 and £6 million a year. This is hardly the kind of cash flow on which a strategy could be founded. The board says that it is having to refuse nearly a third of grant applications that deserve to succeed. Maybe it should be worrying instead that, with such tiny sums of money at its disposal, it is not much more seriously overwhelmed.

Balkanization

To be fair to all concerned, these sums are not the whole of what the British research councils spend on the support of academic research. The specialized spending boards into which SERC is balkanized also make grants to academics but, of necessity, the successful applicants there are almost always those whose projects dovetail neatly with the planned use of some machine, observatory, Earth satellite or the like. Other research councils chip in as well; the Medical Research Council spends more on academic biological research than does the science board by a factor of two; the Agricultural and Food Research Council, more deeply committed to its own institutes, also helps, as does even the Natural Environment Research Council. The result, however, is a conspicuous lopsidedness. Why are physics and chemistry research, core sciences if there are any, supported on such a miserly scale?

The usual answer is that that is how the pattern of spending has developed, and that the supply of research grants cannot be too different from the pattern of demand, because the mechanism is self-correcting. This complacent argument overlooks the simple truth that if you starve a field of funds, and spend the best part of a decade telling academic scientists that they would be better employed in other fields, in information technology or engineering for example, they will eventually go elsewhere, intellectually or geographically.

Core science

In Britain, the problems of core science have been multiplied by the perverse pursuit of over-rational stratagems for economizing in resources. High-powered lasers are in fashion? Then the managers of the research enterprise quickly calculate that they could not provide every likely group with up-to-date equipment so let there be a single central facility that everybody can use, well designed (and slowly built). This is probably the most effective device yet discovered for turning honest scientists into committee-people, skilled above all at winning allocations of time at facilities which are always more elaborate than would have been necessary for a single purpose — and whose lifetime is assured for years and even decades to come. So it turns out that with the passage of time, young men who embark with enthusiasm on working as attendants of the big machines (even the small big machines) discover that they are no longer practitioners of the craft that attracted them but rather managers, negotiators, sometimes even diplomats.

Nobody suggests that it would be possible to turn back the clock so far that the practice of science in the physical sciences would be exclusively modelled on what happened in the nineteenth century. It is however likely, with the present distribution of resources in Britain between machine science and small-scale science, that the pendulum has swung far too far towards the machines. There is no evidence that people dislike working with the large machines but that is not the point. What matters is that the way in which the machines claim people's allegiance for years on end ensures that the community of scientists in a country as small as Britain is less flexible than it might be, less able to seize new opportunities.

The science board seems at least to have understood the way in which changes should be brought about. Its strategy document says that it needs more money and that if it had more money it would give first priority to research grants and the last to the strengthening of machine facilities. But how long does the science board think it would take to effect a noticeable change in the pattern of scientific research if on the one hand it is going to adjust its distribution of resources only when the total is increasing and if at the same time it follows its own prescription of giving particular attention to projects which have industrial potential? One of the constantly repeated mistakes in the management of British civil science in the past few decades is that with each new economic crisis, the research councils whose responsibility is to ensure the health of basic science have felt it necessary to demonstrate that they too have to put their shoulders to the wheel, helping with chemical engineering one decade, information technology the next.

Mercifully, there are signs that even this preoccupation may soon be modified. In the past six months, SERC, recognizing the dangers of over-dependence on machines, has tried to create a set of circumstances in which the two big spenders among its committees, the astronomy, space and radio board and the nuclear physics board, would be merged, presumably so that they would then take a more sceptical view of what their enforced partners were supporting. It is a well-known failing of even the best intentioned systems for distributing money for research that peer review is harder to trust as the scale of projects grows. Unfortunately, SERC has for the time being defeated its chairman's plan to bring about this marriage. He (or his successor) should not however let the matter rest there. The case for having rational means of distinguishing between the merits of different proposals is too strong to be forgotten.

The grant-making establishment needs also to safeguard itself against repetition of the mistakes that have recently caused such trouble. Logical though it is to think of serving many users and saving money at the same time by the provision of central facilities which all experimenters can use, the system is also a recipe for diseconomy. Would it not be better, as in the United States, that if a person thinks it would be valuable to have a machine for accelerating particles, or producing intense monochromatic beams of light, or even perhaps a machine for producing neutrinos, he should not be prevented from applying for the money he needs by the argument that the project is too big for one man to handle? Of course that is literally true. But elsewhere, in the United States particularly, there is now a long record of successful exploitation of the principle that the most enthusiastic user of a novel kind of machine is likely to be the man who gave the reasons why it should be built. And then, of course, if two people have the same idea for a new machine at the same time, there can be a competition. Either way, the enterprise is likely to be carried out more economically than would otherwise be possible, fewer people will acquire a vested interest in its perpetual continuation and, indeed, there would be many occasions when designers of new experiments on a large scale were treading on their own heels, anxious to get rid of what they had been anxious to build only a little while earlier. □

American Association for the Advancement of Science — New York

Administration hints at clampdown on biotechnology exports

AMID charges from the Department of Defense (DoD) and US intelligence agencies that the Soviet Union is applying biotechnology to biological warfare research, the Reagan Administration is beginning to suggest that biotechnology may have to be brought under export control regulations designed to halt the flow of "militarily critical technologies" to potential adversaries.

The Reagan Administration's interpretation of the export control rules has been the subject of controversy, particularly in the crackdown on exports of computer components and in DoD's recent efforts to shut out foreign nationals — even those from NATO countries — from scientific meetings held under its sponsorship.

At the AAAS meeting here, John Birkner of the Defense Intelligence Agency predicted that "dual use" biotechnology — items with both peaceful and military applications — would sooner or later have to be restricted. He asked scientists in industry and at universities to help DoD learn "how our technology may be turned against us" so that a "prudent" list of militarily critical technologies can be compiled for biotechnology.

Items listed as militarily critical can be exported only with a licence issued by the Department of Commerce. To qualify for the list, a technology must not already be possessed by "principal adversaries" nor available to them from a third party. Birkner said that specialized polymers, synthetic elastomers and detectors for chemical and biological warfare agents would all be likely candidates for inclusion on the list.

The charges that the Soviet Union is already exploiting biotechnology for biological warfare have emerged in recent weeks from official DoD sources, the Central Intelligence Agency and a series of articles in the *Wall Street Journal*. DoD's recent report on Soviet military power asserts that the Soviets have an active research and development programme to investigate the utility of biological weapons; Birkner said that "there are at least seven biological warfare centres in the Soviet Union that are under strict military control" and which are applying "selected aspects of genetic engineering to their work". The *Wall Street Journal* articles made similar accusations, and in turn have been sharply criticized by many US researchers for imputing sinister motives to research activities that are indistinguishable from US efforts in biotechnology and basic genetic engineering.

The putative activities of the Soviet Union would constitute a violation of the 1975 convention banning the possession or development of biological weapons. The United States had earlier accused the Soviets of violating the treaty (and the 1925 chemical warfare treaty) by using toxin and chemical weapons in Afghanistan and South-East Asia.

Meanwhile, some new light has been shed on the US military's own programme of recombinant DNA and hybridoma research. Thomas Dashiell of the Office of the Secretary of Defense appeared at the meeting here with a list of 43 biotechnology research projects funded by DoD as of 30 April. The bulk of the projects deal with development of vaccines against disease endemic in areas where US troops might be sent or against possible biological warfare agents, such as anthrax. Other projects are aimed at developing enzymes to decontaminate chemical warfare agents and at producing materials such as epoxies, lubricant stabilizers, biofuels and marine antifouling agents.

The research, which is divided between in-house efforts (mainly at Fort Detrick in Frederick, Maryland — the former biological warfare research establishment) and sponsored research at universities (among them Massachusetts Institute of Technology, Texas A&M University, Rockefeller University, Purdue University and the Universities of California, Massachusetts, and Maryland), is all unclassified. Dashiell suggested, however, that if the research moves beyond the basic stage — which he says is not likely to happen for eight years at least — some of the development work may be subject to secrecy restrictions.

Stephen Budiansky

Peter David adds: In Washington meanwhile, Congress received an unexpected signal last week that the Reagan Administration may be softening its stance on the control and publication of research findings. Dr Edith Martin, Deputy Under-Secretary of Defense for research and engineering, announced during a hearing of the House Science and Technology Committee that the administration intended to rely on formal classification procedures to keep sensitive research out of the hands of foreign nations.

Apparently reading from the still-unpublished report of a senior interagency group examining technology transfer, Dr Martin said it was the policy of the administration that "no restrictions may be placed on the conduct or reporting of research that has not received national security classification".

Although the statement referred specifically to "fundamental" research, it was taken by observers at the AAAS meeting to imply that the Department of Defense (DoD) had dropped a controversial plan to restrict the publication of applied research that was sensitive but not formally classified. Drafted as part of a wide-ranging review of the Pentagon's approach to international technology transfer, the plan would have insisted that DoD contracts for work that was both "applied" and "sensitive" should in future give the Pentagon the right to prevent publication of the resulting findings.

In meetings with universities in recent months, Dr Martin had argued that total reliance on classification, in which it would be necessary to show that publication of the research would constitute a direct threat to national security, was too inflexible. But her proposal to create a new category of sensitive research whose publication would be controlled by DoD was fiercely opposed. Three universities — Stanford and the California and Massachusetts Institutes of Technology — wrote to DoD and to the White House science office claiming it would prevent them from undertaking certain categories of research for DoD. □

Europe uneasy at CERN rival

DR Herwig Schopper, director general of the European Organization for Nuclear Research (CERN), is sowing seeds of dis sent to the ambitious US plan for a massive new particle accelerator. Speaking here at the AAAS meeting, Schopper suggested that the tunnel now being completed for LEP, CERN's 100-GeV electron positron collider, could be used for a future proton machine with capabilities approaching those of the US design, and at substantially lower cost.

While careful to stress the importance of "complementarity" between European and US efforts in high-energy physics, Schopper clearly implied that the United States could find itself competing with CERN for the claim to the next large accelerator.

The United States made an initial commitment to its proton collider, known formally as the Superconducting Super Collider (SSC) (and earlier known as the "Desertron"), last year when the High Energy Physics Advisory Panel endorsed the concept. The panel, which represents the particle physics research community and which makes recommendations to the Department of Energy (DoE), at the same time voted to abandon Brookhaven ▶

National Laboratory's unfinished ISABELLE accelerator, recognizing the unprecedented concentration of technical and financial support that SSC would require.

As now envisaged, SSC would attain centre-of-mass energies in the neighbourhood of 40 TeV — sufficient, in the view of current theory, to explore the so-called Higgs sector. Leon Lederman, director of Fermilab, who also spoke here, said that experimental exploration of this energy region is vital to resolving the "crisis" that Lederman says his "theoretical colleagues" now find themselves in. "They're speculating wildly", he says, for lack of solid data.

According to cost estimates developed earlier this year at a marathon session at Lawrence Berkeley Laboratory (some 150 researchers from the national laboratories and universities were, as one participant put it, locked in a room by Department of Energy officials until they could agree on some definite numbers to be used in preparing next year's budget request), SSC could be built using existing magnet technologies for $3,000 million, with a completion date in 1994. DoE is now considering whether to submit a request for research and development funds in the budget for fiscal year 1986. Lederman says that it would probably take two or three years to develop a definite design that optimizes costs. The "reference design" document produced at Lawrence Berkeley considered three different combinations of ring size and magnet field strength, and concluded that costs would be roughly eqaual in each case. The original idea of SSC, and thus the name Desertron, was to use relatively low field, "cheap" magnets in an enormous ring that could presumably fit nowhere but the southwestern desert.

Lederman said he considered the $3,000 million figure to be a maximum, as it assumes the use of existing "dumb" magnet technology, as he put it.

Schopper, on the other hand, placed a price tag of $500 million on the European version of the proton collider, the cost savings coming from the use of CERN's existing tunnel and injectors. The energy of the machine, however, would be only 10 to 12 TeV if existing magnets technology is assumed, although it could be as much as 18 TeV if the as yet undeveloped Nb3n 10-tesla magnets become available in time.

Both Lederman and Schopper spoke of the need to coordinate US and European plans; both also said they had little idea how this could actually be accomplished. Lederman said, however, that it would probably be a political impossibility to persuade the countries in question to build both machines. He also questioned whether the CERN proton collider's energies would be sufficient to explore the Higgs sector.

Schopper, in the face of repeated questions about the relative cost-effectiveness of the two plans, said "It's no use starting a fight now"; more work needs to be done on the technology before a decision can be made, he said. And, apparently referring to hints of some new and puzzling discoveries coming out of CERN's SPS collider, suggested that in the two to three years needed for technology development, "the physics might be different".

Schopper suggested that another possible add-on to the LEP tunnel — one that certainly would not compete with SSC — would be an electron–proton collider.

Meanwhile, the United States is already worrying about selling the most expensive basic research project yet to Congress. Presidential science adviser George Keyworth was recently in Japan trying to drum up some tangible support from the Japanese Government for the project. And DoE officials are only half facetious when they suggest that the SSC ring might be arranged to pass through at least three states to boost regional support in Congress.

Intellectual property

Consider the monoclonals

BRITISH universities seem to be rebelling against the mounting pressure on them to become more responsive to commercial considerations. The Committee of Vice-chancellors and Principals (CVCP), in a preliminary response to a government discussion paper on intellectual property rights, rejects the idea that universities should seek to protect research inventions with patents wherever possible, citing as an example the "serious disadvantages for generations of investigators" if monoclonal antibodies had been rigorously protected. And in a formal reply to a plea by the Engineering Council to spend more of their grant on training engineers, the committee reaffirms its opposition to having grants specially earmarked for engineering and its distaste for a rapid increase in provision for science and technology at the expense of other subjects.

CVCP dismisses the government's "green paper" on intellectual property, published at the end of last year, as "somewhat superficial". The paper made some radical suggestions on how the Patent Office might be moved out of the civil service and suggested some changes to intellectual property law. But, say vice-chancellors, it pays too little regard to the difficult balance that university researchers must maintain between possibilities for commercial exploitation and their commitment to intellectual progress. And CVCP dismisses the "implied criticism" that academics exchange information too freely and take protection too rarely. Universities have, the committee says, a clear policy on patenting. The government should, before considering legislation, thoroughly examine all aspects of intellectual property, including such problem areas as copyright and computer software. Some are concerned that biotechnology, in particular, might be adversely affected if very broad patents impede research.

Beyond this CVCP does not go, thus perhaps inviting the criticism that it, too, is being somewhat superficial. The committee excuses itself by blaming an unrealistic timetable for comment imposed by the Department of Education and Science. Discussion has had to be brief and consultation has been less than complete. A fuller response will be prepared in due course.

The committee has however managed to find the time to prepare a full response to the Engineering Council, which earlier this year accused universities of not using their grant in the way that was intended. The council announced that it wanted a ten per cent swing in student numbers from arts-based to science-based subjects within the decade. That objective is thought by vice-chancellors to be totally unrealistic, given the pressures that already exist on the university system, and many vice-chancellors feel the Engineering Council has weakened its case by overstating it.

Tim Beardsley

Argentinians safe

Washington

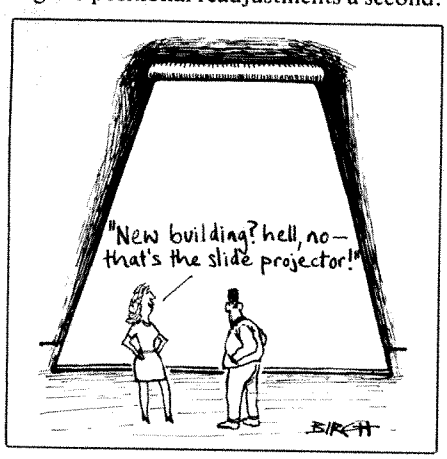
THE new democratic government in Argentina is wasting no time in trying to re-establish contacts with expatriate Argentinian scientists and to offer assurances that the personal and political vendettas of past regimes will not be repeated.

Dr Carlos Abeledo, under-secretary for science promotion and director of the national research council of Argentina, was in the United States last week to spread the word among the hundreds of Argentinian scientists here that if they want to return they will be welcome and there will be financial support for them. Abeledo said that he did not expect more than a few dozen to take up the offer this year, but that he was also hoping to involve the expatriate scientists in the country's scientific effort through such activities as reviewing for Argentinian scientific journals, reviewing grant applications, and taking in Argentinian research fellows.

Abeledo was due to meet with some 200 Argentinian scientists at the American Association for the Advancement of Science meeting in new York; the previous week he was present at a gathering of 100 Argentinian scientists now living in France.

Albeledo was among the hundred or so scientists sacked in 1976–77 for political — and sometimes personal — reasons by the government. One of the first acts of the new government this year was to recognize the right of those scientists to return to their positions.

Stephen Budiansky



US universities

Benefactions abound

Washington

UNIVERSITIES in the United States are enjoying a spectacularly profitable spring this year. In April alone, the University of Texas at Austin announced that an $8 million donation by an anonymous Texan would enable it to endow 32 new chairs in science and engineering, and the University of California said that it had received the biggest single private gift in its history: $36 million for a new telescope. There may be more to come. According to a new survey, universities and colleges are becoming America's favourite philanthropy: voluntary contributions to higher education reached a staggering $5,000 million in 1982–83, an increase of 6 per cent over the previous year.

The University of California gift comes in the form of cash, property and art masterpieces bequeathed by Mrs Marion Hoffman, widow of the car dealer, Max Hoffman. The money is to form part of a $100 million fund with which the university intends to build a 10-metre telescope of novel design at Mauna Kea on Hawaii by the end of the decade. It will consist of 36 six-foot hexagonal mirrors arrayed to form a continuous optical surface. The mirrors will be kept aligned to a precise optical figure by a system of computer-controlled sensors and actuators capable of performing 100 positional readjustments a second.

It will have four times the light-gathering power of the venerable Hale Telescope on Mount Palomar.

A bonanza of similar proportions will befall the University of Texas as a result of the $8 million donation by a local industrialist. The $8 million is to be matched by five Texan foundations, and another $16 million will come from the state-funded Permanent University Fund. Together, the package will enable the university to establish 32 chairs endowed for $1 million each. The university expects filling the chairs to take several years. It will be recruiting in chemistry, physics, mathematics, molecular biology, computer engineering, microelectronics, computer-assisted design and manufacturing and materials engineering.

The universities of California and Texas are traditionally among the biggest recipients of private and corporate philanthropy. A survey now published by the Council for Financial Aid to Education reports that, in 1982–83, voluntary donations to the University of Texas exceeded $107 million, while the University of California received more than $135 million. In proportion to their size, however, neither matches Harvard and Stanford, which received donations of more than $126 million and $91 million respectively.

Where is all this money coming from? Increasingly, it seems, from private business. Corporate philanthropy has at last outstripped donations from foundations and reached more than $1,000 million in 1982–83, 14 per cent more than in the previous year. That means that the lion's share of donations comes from four distinct sources: corporations, foundations, alumni and private individuals. Each gives about $1,000 million in a year, while religious denominations give an estimated $200 million in total.

Nearly a third ($1,500 million) of all the money contributed is in the form of unrestricted gifts. Some $300 million is earmarked for academic salaries and $750 million for research. But the gifts are distributed extremely unevenly. Major private universities receive an average of $21 million each, about five times as much as their public counterparts. And ten universities accounted for a full $690 million of the gifts in 1982–83. Harvard and Stanford lead the pack. Eight other institutions, receiving between $50 million and $60 million each, are: Minnesota, Columbia, Cornell, Massachusetts Institute of Technology, Yale, Princeton, Southern California and Pennsylvania.

Peter David

Genetic engineering

Picking up the pieces

Washington

PROPOSALS from private companies for the field-testing of recombinant organisms will still be considered by the Recombinant DNA Advisory Committee (RAC) of the US National Institutes of Health (NIH), despite the cloud created by a federal district court ruling in favour of anti-genetic-engineering activist Jeremy Rifkin (see *Nature* 24 May, p.296). That ruling has temporarily halted Dr Steven Lindow's experiment on ice-nucleating bacteria and barred RAC from approving any other experiments involving NIH funds that would deliberately release recombinant DNA into the environment.

But the ruling specifically exempted private companies, which are not legally bound by RAC decisions, although they have been complying on a voluntary basis. The reasoning was that if RAC was not allowed to consider proposals from private companies, the companies could simply proceed without RAC's approval.

Although a final decision has not been made by NIH, RAC staff said last week that as far as they knew two deliberate release proposals from private companies were still on the agenda for the next RAC meeting, on 1 June. Advanced Genetic Sciences Inc. (AGS) is seeking approval for a field trial virtually identical to Lindow's, and Cetus Madison is submitting a proposal for the field testing of plants with genetically-engineered disease resistance. RAC will hear all of the Cetus Madison proposal and part of the AGS proposal in closed session, in accordance with the standard procedures for the safeguarding of trade secrets.

In a letter to the executive director of RAC dated 18 May, Rifkin requested a moratorium on consideration of all deliberate-release proposals and said he was appealing the district court's decision on that point. Rifkin's attorney, however, said they would not appeal until RAC had decided definitely on how to handle the June meeting.

Meanwhile, the University of California has filed an emergency appeal against the temporary injunction against Lindow's experiment. According to Lindow, the experiment must begin by around 25 May or be postponed until autumn. William Anderson, attorney for the university, said that the court failed to examine RAC's deliberations on the Lindow proposal, which, he said, met the legal requirements of a "hard look" at environmental effects. The appeal also argues that Rifkin failed to exhaust available administrative remedies before filing suit, as he failed to file comments or attend either of the RAC meetings at which the Lindow proposal was discussed. Rifkin says he did not know about those meetings and was out of town when they took place; announcements of the meetings and requests for public comment were, however, published in the *Federal Register*.

Rifkin's attorney, Edward Lee Rogers, said that he thought neither argument would stand up; the *Federal Register* announcement was "cryptic", he said, and did not make clear that this was the first deliberate-release proposal; and he said the "equivalency" defence — that RAC in fact carried out the equivalent of a legally-required environmental assessment — is available only to agencies whose principal responsibility — and thus expertise — is with environmental issues.

Stephen Budiansky

Venture capital

Stealing universities' thunder?

A NOVEL Anglo-US joint venture launched this week aims to sponsor the commercial development of research projects carried out in British universities. The two partners in the new venture, to be called the Research Corporation Trust, are Investors in Industry (3i) and the Research Corporation, of New York. The trust will, through a subsidiary, evaluate, patent and license inventions throughout their lifetimes and will use the proceeds to sponsor more university-based research.

The trust is likely to prove controversial. In return for its free advisory and patenting service to universities the trust will normally expect resulting patents to be made over to it. The obvious question is whether the fruits of research supported by the British taxpayer might not be enjoyed overseas. Mr Ivan Momtchiloff, a general manager of 3i and a director of Research Corporation Trust, said recently that British inventions would be exploited by the trust in Britain "where humanly possible", unless to do so was "obviously silly". A slightly different line has been taken by Dr John P. Schaefer, president of Research Corporation, who says the trust "will not only help strengthen science and technology in the United Kingdom but also lead to a mutually beneficial exchange of technology between the United States and Europe."

The two partners in the new trust are not obvious bedfellows. Research Corporation in the United States is incorporated under not-for-profit law, and the new trust in Britain will, it is hoped, receive charitable status. The Investors in Industry group is, however, an established large industrial investment group, backed by major British banks, whose goal is undeniably to make a profit. Mr Momtchiloff says that 3i will profit from any companies that it acquires or spawns to develop the inventions originated by the trust, and from licence income.

A major spur to the formation of the new trust has been the recent abolition of the first-refusal right on much publicly-funded British research previously enjoyed by the National Research Development Corporation (now part of the British Technology Group). The 3i group has previously formed companies based on university research but the process has often been protracted and difficult. The group was, according to Momtchiloff, considering a new approach based on research grants when it learnt that Research Corporation in the United States was thinking of setting up a British operation; a partnership was the natural result. The corporation already has the special skills and extensive experience of working with university departments to enable a similar scheme to be set up in Britain. The trust will also benefit from Research Corporation's established patenting and legal support services.

The initial capital in the new scheme is suprisingly modest — £1 million from each of the two partners, with an additional £50,000 each to start the ball of research grants and license income rolling. Many of the initial grants will be for only a few thousand pounds — to buy a specific item of equipment for instance. The trust will seek mainly to interest young researchers who may have more difficulty than their elders in attracting research funds.

The trust's share of royalty income, net of expenditure, will be returned from the subsidiary operating company to be distributed as more research grants. In the United States the arrangement between universities and the new trust's parent company is that the institutions take 60 per cent of royalties and the trust 40 per cent. Arrangements between institutions and their employees are more variable, and the opportunity to take an equity stake in a new company would depend on the individual circumstances. **Tim Beardsley**

A UK venture

A VENTURE capital fund launched last week in Britain will provide £15 million over 4 years to invest in new and emerging private companies working in high technology. The Charterhouse Japhet Venture Fund has already raised this sum and has made its first investments. Its preferred areas are telecommunications, microelectronics, health care and biosciences.

The capital that the new fund has available puts it immediately in the ranks of the larger venture funds in Britain. The investors are prominent UK pension funds. The investment directors are Dr John Walker, who comes from the Investors in Industry group, and Mr Ron Sheldon. Walker emphasizes that his approach extends to providing active management support and marketing experience.

Most of the investments will be of more than £250,000, but some "seed capital" for new product development will also be available. The £15 million will spread over 20 to 25 major investments, of which the fund will be the lead investor in about a half. Walker is critical of other venture capital funds that attempt to gain control over a young company by taking a majority investment. He swears that the new Charterhouse fund will always take a minority stake so that control remains with the originator of the company, a principle Walker considers extremely important.

Walker has a significant personal stake in the new fund. He declines to reveal the amount but admits that he "probably won't have to worry about cash" if the fund succeeds. He and Sheldon, by demonstrating their personal commitment, will inspire company management to confidence, he believes. Tim Beardsley

Agriculture

Old crop ripe for revival

Waalre, The Netherlands

ONE of the first plants to be exploited by man in South-East Asia and Oceania could once again become a major commercial crop in the region if the efforts of Professor Michiel Flach of the Agricultural University at Wageningen bear fruit.

The crop is the sago palm, natural stands of which cover some 2 million hectares in Indonesia, Papua New Guinea and the Philippines. These areas are underexploited, says Professor Flach, in a region where it would be prohibitively expensive to plant other crops. There are also 200,000 hectares of planted sago stands, mostly in Malaysia. There is a small but growing market for sago starch, not only for food use and industry (textiles and paper) but also for production of high-fructose syrup.

Professor Flach's espousal of the sago cause began in 1970, and with backing from the World Bank, the Food and Agriculture Organization (FAO) and the Dutch Government he organized international symposia on the subject in 1977 and 1980. Earlier this year there was a discussion on sago at an FAO workshop in Jakarta, Indonesia and Flach is now organizing a third symposium — this time in Japan where there is considerable interest in the crop.

A new sago starch factory is to be constructed in Indonesia, where the cultivated stands can produce at the rate of 2.5 to 5 tonnes per hectare. World starch production from cereals is about 1,360 million tonnes so the 2.2 million hectares of sago palm could produce only some 1.5 per cent of world production, but in some areas the contribution from sago palm could be important. In Sarawak, for instance, the palm is an important crop in peaty soils, and in swampy areas in the tropics sago palm will grow quickly (8 years to maturity compared with 13 years in other areas). In food energy terms the palm will out-yield any other crop.

Professor Flach does not see pure sago starch as a challenge to the central role of rice, but in Indonesia more and more people are eating bread, and sago starch added to bread flour can significantly improve quality. The country imports around a million tonnes of grain a year, and any application of the indigenous sago palm that would help reduce imports would be of vital importance.

Most of the work on sago palm is directed towards production in Indonesia, where the ministry of public works is studying the potential use of coastal swamps in sago growing. And now there is a major project sponsored by the World Bank. "Suddenly nearly everybody is working in the field", says a surprised Professor Flach. **Casper Schuuring**

Software copyright

MITI retreat on "piracy"

Tokyo

JAPAN's Ministry of International Trade and Industry (MITI) has abandoned its controversial plans to make changes in the laws governing software copyright — changes which, in the US view, would have made "worldwide software piracy legal". But plans are going ahead rapidly to strengthen the software industry by setting up a new Y 290 million (£900,000) database research centre and by merging software organizations into a single promotional group.

What worries MITI is that Japan's software industry is not growing sufficiently rapidly to enable it to catch up with the West. In the United States and Europe, the explosive growth of the software industry has been fired by the appearance of huge numbers of small entrepreneurial software houses selling software packages wherever a niche can be found for them. Japan is only just entering this stage. Until now, growth has been hampered by big businesses which want to construct their own software or have its specially built for themselves alone, rather than buying a package off the shelf.

To try to boost the industry, MITI called for a new law "more clearly to protect the rights of computer programmers" and to give programmers the right to "allow or refuse the use of software by a third party". At the moment, software rights are provided in an ill-defined way by copyright laws administered by the Ministry of Education, Culture and Science (MESC)'s Cultural Affairs Agency.

But instead of the fifty years' protection given under Japanese copyright law or the seventy-five years given under US law, MITI proposed that only fifteen years be guaranteed — even though some of the early US software still in use is already about that old. What is more, the new law made it possible to require a software developer to sell his software in exchange for a "reasonable payment", whether or not he wanted to sell it, when the sale was "in the public interest" or when use was refused without a "justifiable reason".

Despite strenuous denials from MITI that the plan had been thought up to help Japanese companies to get access to US software technology, the US software industry reacted with fury. Many also felt that the successful lawsuit brought by IBM against Fujitsu and Hitachi — two of Japan's top computer makers — which forced them to pay huge sums in compensation for allegedly copying and reselling IBM software had stirred MITI into proposing such a radical change in the law.

Joining in the US protest was MESC's Cultural Affairs Agency, which refused under any circumstances to yield its control of software copyright to MITI. The combined opposition was eventually sufficient to overwhelm MITI, but not before a remarkable series of semantic squabbles between MESC and MITI over whether software was akin to literature, and thus clearly material that should be protected by copyright, or an "industrial process" which MITI could claim should be dealt with by its patent department.

While MITI's plans for new software laws have reached a dead end, progress has been made this past week in regrouping Japan's database research and development groups. MITI is to use funds from one of its more profitable sidelines — running the nation's bicycle races — to draw together the fragmented database industry. Under the bicycle race law, MITI supervises the "fair and safe conduct of all bicycle races" and puts the profits into the improvement of "bicycle and mechanical technology" as well as improvements in "medical care and public hygiene". Although funding databases may be stretching the law's original intentions, Y170 million has been earmarked from the fund as an initial payment to help set up a new institute for database research. A further Y120 million is to be provided by a group of 20 industrial companies, including Mitsubishi, Hitachi, Toshiba, NEC and Fujitsu, that MITI is bringing together along with a number of academic researchers in the universities to form the new group.

The aim is to bring database development up to Western levels. MITI was spurred into action by the result of a survey showing that 679 databases were in use in Japan — ranging from economic statistics to chemical literature — but only 157 (23 per cent) of them had been developed inside the country. Major problems have yet to be overcome, however, to bring together the different groups working on databases. Some databases are already being developed in universities and in the Japan Information Centre of Science and Technology with support from the Science and Technology Agency.

A large database is also under construction in MITI's patent office to store patent information. As it covers a very wide range of fields, it is essential that it be properly integrated into the overall strategy. The problem is the familiar one in Japan of getting competing ministries to work together — particularly difficult in this case because part of MITI's aim in setting up the group was to establish that databases belonged in its territory rather than that of the Ministry of Posts and Telecommunications. The problems are expected to be resolved by the summer and the location and structure of the centre to be agreed upon.

A new industrial grouping is also almost ready for those involved in other areas of software development. Both personal and commercial software are now to be grouped together into one umbrella organization under MITI's aegis to provide a centralized group capable of more "organic" activity. The details of the new organization will be released by MITI at the end of the month.

Alun Anderson

Hungarian science

Making the most of society

HUNGARIAN biology must come to terms with the challenge of computers, information technology and systems analysis, Dr Janos Szentagothai, president of the Hungarian Academy of Sciences, told the academy's general assembly last month. The theme of the meeting was the relationship between biology and society — an important subject in a country with a considerable agricultural and food industry and environmental legislation going back to the mid-nineteenth century.

Dr Szentagothai concentrated on three main topics: the academy's role as scientific coordinator in the preparation of socio-economic decisions, basic research of "outstanding future importance" and participation in certain aspects of scientific public life. He stressed the setbacks suffered by Hungarian science as a result of the swingeing cuts in research expenditure two years ago. Even a year's moratorium on spending on new equipment and the servicing of equipment already purchased from abroad had, he said, greatly hindered the utilization of the country's leading intellectual resources.

During the meeting, Deputy Premier Jozsef Marjai announced a special government credit of 200 million forints (£33 million) for research, in addition to what had been originally planned, most of it to be allocated by the academy for basic research. Nevertheless, Dr Lenart Pal, the general secretary of the academy, urged that other ways of generating research funds must be encouraged, such as the formation of "profitable partnerships and subsidiaries" by research institutes and industry.

It was, however, what Dr Szentagothai called "scientific public life" which provided the major innovation this year. Starting in 1985, the academy's elections are to be "democratized", with multiple candidates for each elective post (president, vice-president, presidium members) and tenure normally restricted to two consecutive five-year terms. A 14-person nominating commission, headed by Professor Bruno Straub, was elected by this year's assembly, and will begin work next March on preparing the necessary lists of candidates.

Vera Rich

Creation research and Noah

SIR — Jukes's commentary on his caricature of creation (*Nature* **308**, 398–400; 1984) is a superb illustration of the unscientific approach of the anti-creationists, especially his conjuring up of "data" to support his polemic. Contrary to Jukes's demonstrably false claims, I have never sent graduate students to do field research on fossil human footprints (although I have led them on Grand Canyon field studies), have never even considered specializing in the "ecology of Noah's Ark", and certainly did not (indeed, could not) synthesize the Taylor's sophisticated museum display with which I am pictured. In the "half (or one-tenth) truth" category, Jukes labours the fact that I wrote a children's book on fossils, but mentions neither that the book was written for Christian families (not at all for public schools) nor that I have co-authored two two-model books with quite a different approach for public schools and, with a highly respected biologist, four widely used college programmed textbooks in biology. His misrepresentation of my colleagues and other aspects of creation science are even further off the mark.

If Jukes (unfortunately rather typical of the anti-creationists) cannot be trusted accurately to report simple, easily obtainable facts verifiable in the present, how can anyone trust his wild-eyed speculations about the complex and unobservable past? It is sad to see a man of Jukes's former stature sink so low. But if *Nature* (a refereed journal?) and those evolutionists who are scientists want to retain a claim to fair and objective scientific rationality, they must separate themselves publicly from Jukes's pitiful tantrum. At least Jukes's article will make thinking people everywhere wonder what is wrong with eliminating "the current methods for teaching evolution" if he exemplifies them.

GARY E. PARKER

Graduate School,
Institute for Creation Research,
2100 Greenfield Drive,
El Cajon, California 92021, USA

● Jukes replies — Professor Parker incorrectly states that I wrote a caricature of "creation". My article was about creationism, a rather different topic.

Parker says he has "never sent graduate students to do field research on human footprints". However, this topic of graduate study is listed in the Institute for Creation Research (ICR) General Catalog (p.14). His "Grand Canyon field studies" would presumably be related to his assertion (Parker, *Dry Bones*, pp.53–54) that the canyon was formed 5,000 years ago by the Great Flood. Although he "did not . . . synthesize the Taylor's sophisticated *sic* museum display", an essentially similar pictorial representation appears in *Dry Bones* p. 24.

Parker's speciality on the ecology of Noah's Ark was inferred by me from *Dry Bones*, which devotes about 16 pages to Noah's Ark and the flood, with pictorial details of the fauna and their food supply.

Parker says I did not mention that *Dry Bones* was written for Christian families. The book is offered for public sale in the ICR book catalogue, where it is described as "fun as well as educational". Despite Parker's assertions, *Dry Bones* has been used for science instruction in at least one public school, where it aroused protest by families that include Christians. I did not find it necessary to publicize his other literary efforts.

I made no misrepresentation of his colleagues; I let them speak for themselves. Parker speaks of my "wild-eyed speculations about the complex and unobservable past". The best response is to quote some of Parker's own pronouncements. For example:

"If the fossils are the plants and animals drowned in Noah's Flood, then they would all be about five to seven thousand years old." (*loc. cit.*, p. 44).

"Before the Flood there were many more plants without seeds compared to seed plants. Plants without seeds didn't survive the Flood as well seed plants."

THOMAS H. JUKES

University of California,
Berkeley, California 94720, USA

Semen and AIDS

SIR — In the letter "Semen and AIDS", by G.M. Shearer and A.S. Rabson (*Nature* 15 March, p.230), some consequences of the physiology of mammalian reproduction appear to have been overlooked.

It is true that semen is deposited in the vagina which is lined by stratified, squamous epithelium, but to reach the ovum sperms have to ascend through the endocervix which is lined by tall columnar (picket) epithelium. This is less likely to be traumatized than the rectal mucosa of a catamite, but its penetration by sperms has been invoked in explaining the origin of carcinoma, while anti-sperm antibodies are common in the human female.

R.E. REWELL

The Old House,
Vowchurch,
Herefordshire HR2 0RB, UK

Fetal viability

SIR — Dr Jansen's choice of definition of "previable" is not as plain as he thinks (*Nature* 26 April, p.768). The *de facto* legal definition of viability is currently 28 weeks in the United Kingdom. The National Health and Medical Research Council (NH & MRC) of Australia suggests 20 weeks; others suggest 22 or 24 weeks as the medical definition of viability. If there is "a point at which extrauterine existence is possible", it would appear to extend over an eight-week period, which is a mathematical contradiction. But, of course, there is no "point", not even 20 weeks, because NH & MRC had to provide a rider to this choice when it stated that "dissection of the fetus should not be carried out while a heartbeat is still apparent or there are other obvious signs of life".

Dr Goodhart's choice of definition (*Nature* 26 April, p.768) appears more reasonable but on analysis is seen to contain a major flaw. The span of human existence from conception until death may be divided into 9 months in a fluid environment and the remainder in an air environment. It is axiomatic to state that the fetus flourishes in its fluid environment, even if it may die in that environment. It is illogical, therefore, to relate the viability of the fetus to its unnatural extrauterine state, just as it would be illogical to relate the viability of those born to their ability to survive in a fluid environment once again.

The best definition of the term "viable" in relation to the embryo or fetus that I could find is "capable of maintaining life". The term "previable" adds nothing to our understanding of intrauterine human existence.

PATRICK W. GILL

Neath General Hospital,
Neath, Glamorgan SA11 2LQ, UK

Biological control

SIR — May I add to the list of methods suggested for control of the fly in a domestic environment? Curiously, neither F.E.G. Cox[1] nor K.L. Bell[2] have considered the possibility of biological control There are several advantages to be gained from establishing a flourishing domestic population of the fly's natural predator, the spider. In particular, application of this means of control would overcome the moral dilemma posed by the choice between swatting the fly and forcibly expelling the insect into an often hostile world.

As in all habitats, it is important to maintain a correct ecological balance within the home or laboratory. Nevertheless, my proposal is preferable to a more drastic form of biological control recorded many years ago. As pointed out by R. Bonne[3], direct predation of flies by humans (particularly elderly females) would seem to be unwise. It can be the beginning of a surprising food chain which, if this anecdotal account is to be believed, can have serious medical consequences and can even result in death in extreme cases.

B A C H E M ... a good name for biologically active peptides.

With its listing of nearly more than 4 000 chemical compounds in the field of **biologically active peptides**, including protected amino acid derivatives and peptide fragments for various methods of peptide synthesis, **BACHEM's new catalog S7 1984/85** is one of the most important tools for all those scientists requiring the most different biologically active peptides for their daily laboratory work. If you did not receive the catalog till now, please, send for your free copy. Nevertheless, if you cannot find a particular peptide in our catalog S7, please do not hesitate to contact our specialists for **custom syntheses** and you will get a prompt quotation.

Are you looking, however, for somebody able to produce large quantities of biologically active peptides or to help you in the transformation of theoretical synthetic considerations into the sometimes cumbersome practice of peptide synthesis, we present us as your partner for **contract work.**
Finally, the following information sheets are now available in new editions:

- BA 035 Substance P, Analogs and Sequence of Substance P, Antagonists of Substance P.
- BA 040 Enkephalins, Endorphins and Opioid Peptides.
- BA 013 Enzyme Substrates.
- BA 003 FMOC-amino Acids.

All peptides described in these information sheets have been synthesized by our peptide synthesis department following the best synthetic ways either by conventional or by solid-phase methods.
Solid-phase chemistry at BACHEM's laboratories is now exclusively performed on the new **LABORTEC Peptide Synthesizer SP 640,** an instrument which convinces by its ease of handling, its high reliability and, especially, by its very low price. You should immediately ask LABORTEC for more information and prices on its Peptide Synthesizer SP 640.

SCANNING ELECTRON MICROSCOPY at MICRO 84

MICRO 84 takes place at the Bloomsbury Crest Hotel in London from July 9th to 13th 1984. MICRO is the largest conference and exhibition concerned with all aspects of light and electron microscopy; and any one microscopical technique, such as SEM, can be easily seen in the context of all the other, allied techniques, available. Today, the SEM is very much a microscopist's workhorse and there is a strong SEM theme running through the whole of MICRO. Some symposia are directed specifically to SEM, others have particular lectures which are relevant to SEM, while in still others complementary techniques are discussed. The following list highlights some of these lectures.

SEM OPIMISATION (Thursday/Friday)	The main objective of this symposium is "Getting the best out of your SEM". A series of tutorial lectures from acknowledged experts will cover the instrument, its operation, specimen preparation, image recording and image interpretation.
TUTORIALS IN MODERN ASPECTS OF MICROSCOPY (Wednesday)	This Symposium is concerned with microscopy and analysis of solid specimens. The lectures will not only cover SEM methods for the non-expert, but also Quantitative Microscopy, Scanning Optical Microscopy, Acoustic Microscopy, and Atom Probe Analysis.
STATE OF THE ART IN TEM AND STEM (Tuesday)	A series of tutorial lectures will deal with imaging and analysis of thin specimens. Among other things, the symposium is intended to update the knowledge of those not working directly with TEM or STEM.
ANALYSIS IN THE SEM (Friday)	In the sessions on X-ray microanalysis and cryo-techniques a number of the presentations specifically deal with preparation of specimens, including by low temperature methods, and their analysis in SEMs.
IMAGE RECORDING (Wednesday)	The symposium will include lectures on optimisation of scanning images, electronic processing of images, and photographic recording of images.
APPLICATION OF SEM (Throughout MICRO)	Throughout MICRO, many of the sessions will include lectures on applications of the SEM to structural observations and microanalysis. Topics including an SEM component include: interfaces in semi-conductors; automated SEM in environmental studies; automatic SEM particle analysis in forensic science; SEM in the study of ancient materials.
EXHIBITION (Throughout MICRO)	It is expected that more than 50 companies will be exhibiting their latest microscopes and ancillary equipment, covering the complete spectrum of instruments and techniques including, of course, full representation of SEM equipment.

Details of the MICRO 84 programme, and further information, are available from:-

The Administrator, Royal Microscopical Society, 37/38 St Clements, OXFORD OX4 1AJ. Telephone: (0865) 248768/721081

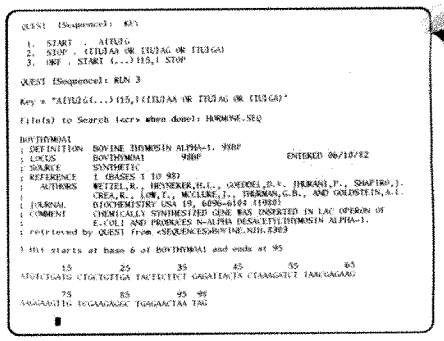
Molecular biologists now using computer tools to locate functional patterns



"As we learn more about the regulatory nature of the various genetic functional domains, and more about what...is recognized within those domains by cellular hardware, our comparative sequence and pattern identification algorithms will have to be generalized..."

—Sadler, Waterman, and Smith, NAR, April 11, 1983

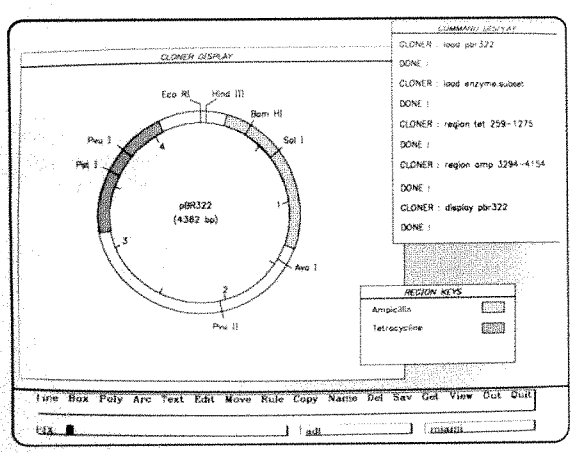
Biological recognition searches

Regulatory sequences in DNA are inherently both redundant and complex. Consequently, a software tool that locates functional patterns must possess great flexibility. IntelliGenetics, the Palo Alto-based scientific software firm has developed this tool.

QUEST searches for biologically important consensus sequences, with any degree of specificity or redundancy. QUEST recognizes redundant patterns, and patterns of patterns. For example, comments in the NIH sequence library can be searched for the pattern "hormone" to generate a file containing hormone encoding sequences. This file can then be searched for three elements defining a gene: start, open reading frame, stop.

Combinations of keys enable QUEST to isolate complex patterns.

CLONER will also:



- store and retrieve maps of vectors and genes whether or not their nucleotide sequences are known
- carry genetic and functional information about regions of the maps
- manipulate map segments identified by restriction site names, by coordinates or by region information
- generate new maps when a vector is modified including all of the region information, restriction sites, gene locations and polarities
- determine whether regions with genetic function have been modified by electronic recombinations
- prepare copy-ready formal maps for reports, proposals or publication

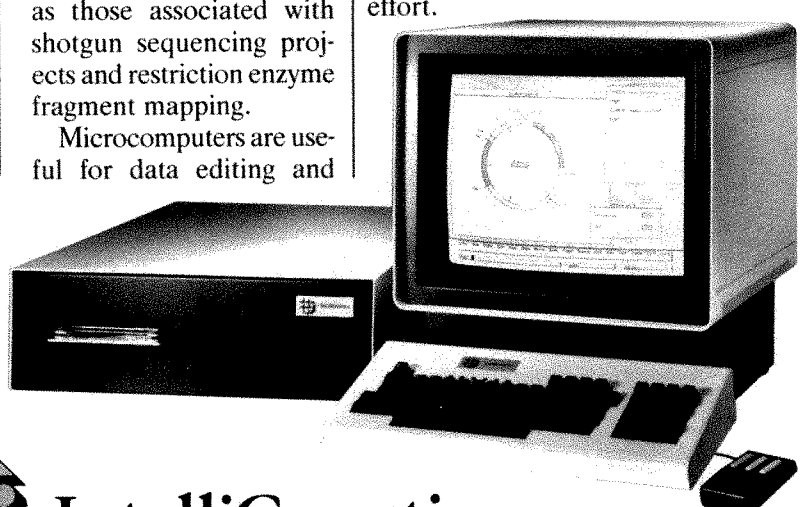
The role of the desktop minicomputer in genetic engineering

Computers allow molecular biologists to gain new insights from their data. IntelliGenetics users are more productive scientifically because their computer tools eliminate many time-consuming tasks such as those associated with shotgun sequencing projects and restriction enzyme fragment mapping.

Microcomputers are useful for data editing and simple, unambiguous sequence searches. However, complex pattern searches require the power of a 32-bit computer.

All of IntelliGenetics' genetic engineering tools, plus databases are contained in a 32-bit UNIX computer: the BION Workstation. BION has been developed by IntelliGenetics to bring computer aided design to molecular biologists.

The bit-map display provides high-resolution maps and multiple windows.



Artificial intelligence based graphics program

A new program currently being developed is a computer aided design tool called CLONER. With this program, the molecular biologist will plan and create new molecules by recombining DNA segments such as vectors, genes, promoters, and enhancer-segments.

Dedicated to complete support

IntelliGenetics is dedicated to improving the quality of science pursued by members of the molecular biology community. More than 400 molecular biologists are now using IntelliGenetics' products in their recombinant DNA research. They have the tools needed to make significant scientific contributions due to IntelliGenetics' ongoing development efforts and staff of molecular biologist computer consultants.

Write for our literature. Let us show you how we can help your research effort.

IntelliGenetics

Blood group and socio-economic class

A report last year, based on a study of a British population, that A blood groups are significantly more common among members of the higher socio-economic groups (classes I and II) has generated a wealth of correspondence, some of which appears in what follows together with a reply from the original authors. The general conclusion seems to be that there can be no general conclusion.

BEARDMORE and Karimi-Booshehri[1] recently reported an association between ABO blood group phenotype and social class. They found that in both sexes the A phenotype was significantly more frequent and the O phenotype significantly less frequent in social classes I and II, the converse being true for social classes III, IV and V. In an attempt to replicate Beardmore and Karimi-Booshehri's findings we have analysed data obtained by the National Child Development Study (NCDS)[2].

The NCDS study commenced as the Perinatal Mortality Survey and involved all children born in Britain during the week 3–9 March 1958. At that time detailed obstetric data were obtained on each child[3,4]. In addition the mothers blood type (ABO and Rh status), her occupational status at commencement of pregnancy, and the occupational status of her father and of her husband were noted. The standard geographical region in which she lived and in which she was born were also recorded.

The occupational status of a married woman can be classified in several ways: (1) by her own socio-economic group (although this necessarily excludes a large number of women who are housewives); (2) on the basis of her father's occupation (when she left school); (3) on the basis of her husband's occupation (in 1958). We have used all three classifications in analysing the relationship between ABO blood group phenotype and social class.

Table 1 presents the breakdown of ABO blood group phenotype by social class and by migrational status. Natives were defined as those born and still living in the same region; all other individuals were classified as migrants. The regions were defined as the 11 standard regions of Britain[5].

For all three classifications of social class we found no evidence to support the notion of either heterogeneity between migrants and natives ABO phenotypic distributions (see Table 1) or an excess of the A phenotype in social classes I and II.

There are several possible reasons for our failure to replicate Beardmore and Karimi-Booshehri's results:

Table 1 Percentages of ABO blood group phenotypes by social class (three classifications) in natives and migrants in Britain

Classification		Blood group	Social class I	II	III	IV	V	Total No.	%
Mother's own	Migrant	A	41.7	39.4	44.4	50.0		327	41.6
		O	50.0	49.8	43.7	42.9		379	48.2
		B	7.6	6.9	9.3	5.4		58	7.4
		AB	0.7	3.9	2.6	1.8		23	2.9

		Total no.	99	709	3,054	1,585	624	6,071	

χ^2 testing:
ABO by social class (migrant) $\chi^2(12) = 17.320$ $P = 0.138$
ABOby social class (native) $\chi^2(12) = 6.551$ $P = 0.886$
ABO by migrational status $\chi^2(12) = 5.062$ $P = 0.167$
Migrational status by social class $\chi^2(4) = 110.064$ $P < 0.001$

			I	II	III	IV	V	Total No.	%
Husband's social class	Migrant	A	37.8	42.2	40.9	45.4	41.2	805	41.4
		O	51.9	46.8	46.4	45.4	43.8	910	46.9
		B	8.9	8.7	9.3	6.9	12.5	173	8.9
		AB	1.4	2.3	3.4	2.3	2.5	54	2.8
		Total no.	214	393	993	262	80	1,942	
	Native	A	43.4	43.4	41.4	40.8	39.2	2,855	41.5
		O	48.4	45.4	46.8	48.6	48.6	3,243	47.1
		B	5.5	7.2	8.9	8.1	8.7	576	8.4
		AB	2.7	4.0	3.0	2.5	3.5	209	3.0
		Total no.	256	917	3,991	1,293	426	6,883	

χ^2 testing:
ABO by social class (migrant) $\chi^2(12) = 9.350$ $P = 0.673$
ABO by social class (native) $\chi^2(12) = 13.629$ $P = 0.325$
ABO by migrational status $\chi^2(3) = 0.874$ $P = 0.832$
Migrational status by social class $\chi^2(4) = 248.342$ $P < 0.001$

Values in parentheses are d.f.

(1) We have looked only at women, whereas Beardmore and Karimi-Booshehri considered both sexes. Nevertheless it is clear from their analysis that their effect is found in both sexes to the same degree. We have attempted to repeat their study by considering both natives and migrants. If this restriction is removed, the sample available for analysis increases, but there still remains no association between ABO blood group status and social class.

(2) The NCDS is a sample of the breeding population of Britain whereas the blood donor data will also include non-breeders. However, it is more likely that the sampling procedure used by the NCDS generates a truly random sample, whereas it is not inconceivable that blood donor data could be biased.

(3) Some evidence of nonrandomness in the blood donor data can be obtained from analysis of the social class distributions. Comparison of each data set with the Registrar General's social class distributions indicates that the NCDS data do not differ markedly from expectation whereas the donor data reveal a significant excess of people in social classes II and V (about 5% and 12% respectively) and relative deficiency of 21% in social class III. There is also marked heterogeneity between NCDS and blood donor samples, for example, using the husband's occupation $\chi^2 = 1{,}746.855$, $P < 0.0001$ (d.f. = 6). Restricting the comparisons to the Registrar-General's standard regions of East and West Riding and south-west England does not affect the above conclusions.

We also note that Beardmore and Karimi-Booshehri found an association only between ABO phenotype and social class and not between migrational status and ABO phenotype, despite a clear association between migrational status and social class.

(4) The ABO phenotype frequencies differ between samples. This is to be expected since we have analysed data from Britain as a whole rather than two geographical regions. However, if we restrict our analysis to the two Registrar-General standard regions mentioned above there is no heterogeneity in ABO phenotypes between samples. Even with this reduced sample we can find no evidence to support Beardmore and Karimi-Booshehri's results.

We have also examined the relationship between social mobility and ABO phenotype, classifying mothers on the basis of her own and her father's social class, as either upwardly mobile, downwardly mobile or non-mobile. Again there was no evidence that this intergenerational social mobility was related to ABO phenotype ($\chi^2 = 1.457$, $P = 0.962$, d.f. = 6).

We thank Mr K. Fogelman, and the National Children's Bureau, for allowing us to re-analyse the data obtained by the National Child Development Study, and Mr E. Roughley, and the Social Science Research Council's Survey Archive for supplying the data.

5. *General Register Offices Census 1961 General Report* (HMSO, London, 1968).

IN a recent article[1], Beardmore and Karimi-Booshehri showed that among 10,000 blood donors from south-west England and Yorkshire there were marked differences in the ABO blood group distribution with social class. The study by Mascie-Taylor and McManus shows an analysis of women who gave birth in the 1 week's national birth survey in 1958. Here we analyse data from a subsequent birth survey. The data relate to 14,384 women resident in Great Britain and who gave birth in the week 5–11 April 1970. The data were collected in the British Births survey[2,3] sponsored by the National Birthday Trust Fund. Well over 95% of all births in England, Scotland, Wales and Northern Ireland were included.

The ABO blood groups of these mothers were compared with their social class, based on the occupation of the husbands, using the Registrar General's Classification of Occupations[4]. Unmarried mothers and those whose husbands' occupations were unclear were omitted ($n = 415$). Ths distribution of ABO blood groups using this classification is shown in Table 2. As shown for the 1958 survey, there was no significant difference between the social classes.

This classification uses the husband's occupation. We did not use that of the woman herself since married pregnant women are often housewives or are only in part-time employment. Information was available, however, concerning the

Table 2 Distribution of ABO blood groups of mothers delivering during 5–11 April 1970 by social class (based on husband's occupation)

Blood group of mother	Social class I	II	III	IV	V	All known
O	368 (48.0%)	822 (47.0%)	4,110 (47.6%)	1,099 (49.2%)	484 (49.0%)	6,883 (47.8%)
A	300 (39.1%)	727 (41.4%)	3,482 (40.3%)	833 37.3%)	373 (37.7%)	5,715 (39.7%)

All known	767 (100.0%)	1,754 (100.0%)	8,642 (100.0%)	2,233 (100.0%)	988 (100.0%)	14,384 (100.0%)

$\chi^2 = 16.1$, d.f = 12, not significant.

Table 3 ABO blood groups according to highest educational qualification of mothers

Highest educational qualification	Blood group O	A	B	AB	All known
None	2,884 (46.9%)	2,510 (40.8%)	574 (9.4%)	180 2.9%)	6,148 (100.0%)
Vocational	778 (49.0%)	623 (39.2%)	142 (9.0%)	45 (2.8%)	1,588 (100.0%)
O-level or equivalent	932 (47.3%)	816 (41.5%)	162 (8.2%)	59 (3.0%)	1,969 (100.0%)
A-level or equivalent	186 (47.2%)	154 (39.1%)	47 (11.9%)	7 (1.8%)	394 (100.0%)
SRN or Certificate of Education	272 (49.6%)	211 (38.4%)	52 (9.4%)	14 (2.6%)	549 (100.0%)
University or college degree or other higher	181 (44.8%)	173 (42.8%)	40 (9.9%)	10 (2.5%)	404 (100.0%)
All known	5,233 (47.3%)	4,487 (40.6%)	1,017 (9.2%)	315 (2.9%)	11,052 (100.0%)

$\chi^2 = 12.7$, d.f = 15, not significant.

educational qualifications of the mothers of the surviving children who were followed up at the age of 5 yr.

As shown in Table 3, there is no evidence for a trend. The evidence of Beardmore and Karimi-Booshehri[1] would suggest that, as the educational qualifications increased, so the proportion of blood group O would decrease, and that of A would increase. True, in our data there were slightly more women with university degrees who had blood group A but this was far from statistically significant ($\chi^2 = 0.5$, d.f = 1).

What, then, might account for the differences between the two studies? Both, of course, have selection biases—in Beardmore and Karimi-Booshehri's data, blood donors only are included and housewives are excluded. In our study, women who are infertile will be excluded and those with high fertility will be more likely to be represented. Although we have no information on the ABO distribution of the former, it has been shown[5] that there is little variation in the distribution of ABO blood groups with the number of pregnancies the woman has already had.

From the data presented here we suggest that, although perhaps true of non-migrant blood donors in Yorkshire and the south-west of England, the finding of more blood group A amongst the upper social classes cannot be extrapolated to the female population as a whole. We know that data from the 1958 birth survey (see above) substantiates our findings. We therefore suggest that the original results[1] are likely to have been due to one of those random statistical variations which must occur by chance.

FROM a χ^2 analysis done on an historic (1953–63) data base, Beardmore and Karimi-Booshehri[1] conclude that attributes influencing occupational type, social mobility and social class result from pleiotropic effects of the ABO alleles (or genes closely linked with them). In the most cogent of their theoretical citations, Herrnstein[2] suggests a possible heritable relationship between social class and intelligence. The authors also cite Arthur Jensen's work[3]. Many recall the social upheaval which accompanied those writings a decade ago and seek to be very parsimonious when making ties between genetics and social class. In that context, I suggest that while the author's hypothesis may be true, it is not yet clearly indicated. Their extensive data seem better interpreted with the notion that there is no direct path from these genes to the behavioural phenotypes. In earlier work concerned with single gene substitutions and behaviour, I have supported the position that while single genes may sometimes have major effects, they often affect many forms of behaviour and that particular psychological traits are frequently influenced by many genes[4]. In the service of that theoretical viewpoint, I have reassembled and recalculated the data on ABO phenotypes as they assort by socio-economic group.

The highly significant outcomes reported[1] do represent real findings with regard to differential distribution of the ABO blood phenotypes across the five socio-economic job categories chosen. However, the authors have repeatedly combined categories to give classes I+II and III+IV+V. They also present the results by comparing the frequency of A phenotypes to the O+B+AB phenotype combination across the socio-economic categories. According to conventional usage in the behavioural sciences[5] information is lost by these procedures. Groups may be (sensibly) combined for an analysis, of course, but this is normally done in order to meet the restrictions regarding minimum expected frequency requirements[5]. With these data, even the least frequent phenotype (AB) provides sample sizes that are adequate for independent χ^2 tests involving all five job categories. Then, since the χ^2 distribution is insensitive to the effects of order, a presentation of the contingencies by cells shows up areas of particular effect. Table 4 gives the obtained frequency divided by the expected frequency ratios for the four ABO phenotypes. It will be seen that for each phenotype there are one or two contingencies which indicate either marked under- or over-representation. The A phenotype is heavily over-represented in job category I and it is marginally high in category II. Phenotypes O, B and AB are all much under-represented in category I but show very different distribution patterns across categories II to V. The AB phenotype is low for category II as well as I and is notably high for category V. The test for the contingencies of Table 4 is significant: χ^2 (d.f. = 12) = 83.03, $P < 0.001$.

This significant statistical outcome, and those of the original report, may represent what can be called 'behavioural pleiotropy'. They do not confirm true pleiotropy, as that term has had meaning in formal genetics. In his classic text Grüneberg[6] discussed genuine and what he called 'spurious' pleiotropy. The rule is that in genuine pleiotropy a single gene controls two or more different traits which it produces directly by the use of different mechanisms. In spurious pleiotropy the gene does two or more things through the same mechanism or else has one effect which causes other things to happen. For example, in mice, A^y, a single gene which has genuine pleiotropic structural effects, for example, increased fat deposition, skeletal enlargement, linear size increase, also shows behavioural (spurious) pleiotropy in that it is also associated with the amount of explorary activity exhibited by C57BL/6J mice[7]. The genuinely pleiotropic traits sum to effect greater body weight which, in turn, accounts for 48% of the variance in activity when $A^y a$ mice are compared with *aa* controls[7]. Thus, the behavioural pleiotropy can be clearly shown statistically but has no genetic basis of its own.

Table 4 Obtained frequency/expected frequency ratios in the total data set of Beardmore and Karimi-Booshehri

Blood phenotype	Socio-economic category I	II	III	IV	V
A	1.34	1.09	0.96	0.99	0.92
O	0.74	0.91	1.06	0.98	1.06
B	0.74	1.08	0.92	1.10	1.02
AB	0.78	0.84	1.00	0.99	1.18

So finally, if we evaluate all of the ABO phenotypes concurrently, both the statistical and the definitional points work together in our understanding (and lack of understanding) concerning how the class differences reported[1] come to be associated with the ABO blood antigen system. We see that one blood phenotype is at comparative advantage for employment, another (the AB phenotype) is at comparative disadvantage, and that (especially in categories II–V) there is a great deal of intra-phenotypic variability across the socio-economic groups. This last point tempers the positive finding that the greatest part of the overall effect is seen at the extremes of the socio-economic continuum.

Thus, it seems a long way from the statistical outcomes to the privilege (or poverty) of class-based experiences, activities, comfort and substance as these subjects have matured from birth to their time of blood donation. In short, when we can show that some genotypically influenced mechanism intervenes between the socio-economic continuum and the discrete phenotypes of the ABO blood system, then we can show pleiotropy. When no mechanism is evident and a statistical outcome is our only basis, then social, cultural or other environmental influences seem more likely to contribute much of the variance to the behavioural pleiotropy found.

THE conclusion of a recent paper[1], that a pleiotropic effect of ABO alleles or linked genes can influence occupational type, seems to be premature. The authors assume that occupational classes are homogenous from an ethno-historical point of view, assortative mating among social classes is not significant, the ABO distribution of donors is similar to that found in the general population, selection on the ABO system is not differently operating in social classes and finally, that the occupation as a variable is the most representative one that defines the stratification of a society.

In Chile, as the authors mention, there is a clear socio-ethno-genetic cline which originated at the Spanish Conquest in 1541 [2,5]. The highest socioeconomic strata of urban areas have gene frequencies for ABO, Rh and other genetic markers similar to those found in Europe, the lowest ones have gene frequencies similar to those expected for a half European–Chilean Aboriginal admixture; middle classes have intermediate values[6]. This cline is present independently of the last two or three generations of European inmigrations[7,8]. Thus the problem is to explain why such a cline has persisted for 17 generations. Aboriginal people disappeared a few generations after the Spanish Conquest. Even 20% socioeconomic random mating should have cut down these gene differences but a strong socioeconomic assortative mating was found in the population of Santiago[9]. This seems to be the explanation for the stability of the socio-genetic cline. There is no reason to assume that a similar mechanism is not operating in England. Since geographical population heterogeneity (like that found also in Chile) due to invasion, settlement and migration is accepted by the authors, it would be necessary to demonstrate that ethnic heterogeneity and assortative mating among occupational classes cannot explain the observed ABO heterogeneity, before accepting the authors' hypothesis.

Blood donors may not represent either the social or the genetic structure of their populations of origin. This could not only be due to higher requirements for O and Rh^- blood groups as the authors assume. If the relationship between ABO and diseases is accepted, and donors are relatives or friends of patients that need transfusions, the ABO distribution of donors may differ from that of the whole population. The authors do not describe the system to call for blood donors. Relatives of patients would increase distortions due to the ABO–disease relationships, colleagues or co-workers of patients would yield a distribution similar to that of the patient social class. These two types of calling donors or other ones, may be differently distributed in occupational classes, thus leading to different ABO distributions among them. We could not use the donors ABO distribution in the high socioeconomic classes because it was different from the mother–infant distribution in a study on socio-economic assortative mating[9]. Moreover, ABO-associated diseases might interact with social classes in an unpredictable way. Furthermore, natural selection operating on the ABO system[10] may differ among social classes, not necessarily at present, but along the history of these classes.

Table 1 of ref. 1 shows that in class I, A migrant donors are less frequent than A native donors (z for proportions[8] = 2.14, $P<0.017$ in south-west England; $z=1.2$, $P<0.11$ in Yorkshire; $z=2.25$, $P<0.013$ in both places together); thus non-A migrant donors are fitter than non-A native donors to be found in class I. This suggests rather a socio-genetic interaction and not a simple gene action on work abilities.

Even accepting that a genetic action associated with ABO system influences the probability of reaching a determined social class, it is not possible to conclude that this gene action is related to skilled/creative or skilled/repetitive occupations. Several other social variables may influence the occupational class an individuals belongs to, such as culture, power, prestige, income and life-style, the latter being rather properties of class and conditioning individual occupation or social mobility. If so, the ABO–occupational class relationship may be true, but only as a circumstantial association.

BEARDMORE and Karimi-Booshehri[1] conclude that "The only apparently reasonable explanation" for the distribution of the I^A allele is that it "confers on those who possess it... abilities significant in determining socio-economic class" (pleiotrophy and linkage being gratuitous qualifiers). No less disingenuously, they assert that "social mobility in the United Kingdom has been, for some generations, a factor which would tend to homogenize initially different gene pools". The question is for how many more generations did social immobility increase the heterogeneity of gene pools? An order of magnitude more than "some"? And how quickly would Karimi-Booshehri and Beardmore expect that heterogeneity to disappear? Figuratively overnight? Apparently.

People who inherit wealth do not start at the starting-line with the rest of the runners, nor do their children or their children's children. It is reasonable to speculate that the present distribution of the I^A allele is one time-frame taken from a gradual sequence of allelic desegregation—the remnant of centuries of tradition during which the mere possession of wealth and social class was enough to ensure the maintenance of same—even in the face of a conspicuous lack of ability, genetic or otherwise.

Brooklyn, New York 10009, USA

1. Beardmore, J. A. & Karimi-Booshehri, F. *Nature* **303**, 522–524 (1983).

BEARDMORE AND KARIMI-BOOSHEHRI REPLY—Mascie-Taylor and McManus's interesting findings on a sample of mothers fail to confirm ours. They consider a number of possible reasons for this. However, they do not take age into account. As the majority of children are born to mothers in their twenties or early thirties there is massive overrepresentation of younger cohorts in their sample. Thus, quite apart from the omission of non-breeders, their sample could not be said to be representative of the female segment of the population in a social sense.

A second important difference in sample compositions between the two

studies is that in Mascie-Taylor and McManus' data for geographical regions are pooled. As there are both average genetic and average socio-economic differences between regions the pooling makes comparisons very difficult.

It is true that our data are nonrandom in terms of social class proportions. We are unable to judge the effect of our exclusion of cases with no or ambiguous occupational labels but it would not be surprising if this produced under-representation of class III especially as one of the commoner labels excluded was 'civil servant'. However there is no obvious mechanism by which such nonrandomness should lead to the results observed.

Mascie-Taylor and McManus are concerned that we have not demonstrated an association between migrational status and ABO type and believe that this may imply mis-classification of social class. Our view is that we have, in this study, been at very considerable pains indeed to avoid mis-classification and that mis-classification is likely to have been at a very low level and lower than other relevant studies. Furthermore it does not follow that an association between migration and ABO type would be detectable as the influences on migration and social class are by no means coincident.

There is a major difficulty in comparing the data of Golding *et al.* with ours. This is that they use the social class of husbands to assign social class to the women in their surveys. There is a correlation between social class of spouses but it is by no means perfect. We were meticulous in our assignment of social class from occupational type. It is interesting to note that recalculation of the total 1958 data ($n = 13{,}969$) collected in the First Perinatal Mortality Survey (of which the data given in Table 1 are a subset) shows the ratio A/O+B+AB to be almost identical in form with our Fig. 1 (Spearman rank correlation in both cases is 0.9, $P \simeq 0.05$). The pattern for the 1970 data quoted by Golding *et al.* is different and indeed the χ^2 testing homogeneity of the 1958 and 1970 data on ABO phenotype frequencies is very close to the 0.05 level of significance. The presence of Northern Ireland data in only the 1970 sample makes it difficult to assess whether it is this or temporal changes which may be responsible for the difference. The 1958 and 1970 samples also differ from each other in social class composition and this, too, complicates comparisons.

Hawkins raises two issues. One concerns the difference which he sees between 'true' and 'spurious' pleiotropy. This is a semantic point. While there may be a case for making distinctions as to types of pleiotropy, many geneticists, including the writers, would subscribe to the view that all effects (whether these affect anatomical, behavioural, biochemical, reproductive or viability aspects of the phenotype) of gene differences can legitimately be considered pleiotropic effects. The second point is concerned with the method of statistical analysis. Pooling of data always leads to loss of information but the main conclusions are unaffected in this example whether we pool or not.

We have partitioned the table into a series of 2×2 tables from each corner. Irrespective of the starting point, it is clear that O, B and AB do not differ over socio-economic class and therefore the table is collapsible in the sense of Bishop, Fienberg and Holland[1]. Thus, only the differences A/(O+B+AB) over social class are relevant. Using the partition method of Daly[2], comparisons which show significance (after pooling blood groups) are those between classes I and II and (I+II) against the rest. Clearly, the significance of the first requires further analysis, but the second accounts for about 50% of the overall χ^2 and cannot be controverted. We also noted a significant effect for classes (I+II+III+IV) against class V, but this only confirms the original conclusions.

Valenzuela takes the view that assortative mating within social classes derived from ethnically different populations is the proper explanation of our results. While ethnic heterogeneity is demonstrable in the Chilean population it is not apparent in the population from which our data are drawn. The difference in the proportions of the A phenotype in migrants and natives is, we think, significant and needs further investigation. In no way do we subscribe to the view, which Valenzuela appears to think we hold, that non-genetic factors are unimportant in determining occupation or other indices of social class.

The other question Valenzuela raises is that of how random a sample of a population is obtained by collection of blood donors. There is a clear need to test this and we hope shortly to examine this question using large samples of newborn and donors from the same region. Nonrandomness, if it occurs, will most likely take the form of over-representation and under-representation of particular phenotypes and the influence of patients on recruitment to donor panels in the UK is unlikely to be significant. One relevant set of data is available in which the distribution of ABO phenotypes can be compared in donors and schoolchildren in one locality. This comes from the work of Allan[3] and is given in Table 5. The phenotype distributions in the two samples agree very well and the very small difference between the two is in the expected direction of slightly more O in the donor sample. It is, of course, possible that such samples differ in social composition.

Table 5 Proportions of ABO phenotypes in two samples from Aberdeen

Sample	Phenotype O	A	B	AB	*N*
Donors	50.27	35.46	10.87	3.40	7,092
Schoolchildren	49.75	36.16	10.72	3.37	17,060

Hartung asks an important question which cannot be answered with assurance. We have, however, with the collaboration of Dr R. Gilbert, attempted to make some crude estimates which are necessarily based on a number of debatable assumptions. Let us suppose that mixing of two populations each polymorphic for genes B^1 and B^2 with the frequencies of B^1 being 0.35 and 0.15 respectively occurs. Even if the gene flow between the two populations ('classes') is as low as 2%, the two classes will have frequencies of B^1 of 0.26 and 0.24 respectively in 56 generations. With 5% gene flow the same frequencies are achieved in 22 generations. Using 25 yr as the length of a generation, the time lapse and gene frequencies are perhaps reasonably applicable to populations at the time of the Saxon invasions of the British Isles which had considerable consequences for power and class. The important point is that these levels of gene flow are very low and it is not unreasonable to suppose that effectively much higher levels of gene flow have operated both in the recent and more distant past, although there is no obvious way of testing this view.

Psychoimmunology before its time

That there is probably a link between the central nervous system and the immune system is easily accepted. The doubt is whether enough is yet known to sustain people's hopes of explanation.

THE notion that emotional disturbance may trigger off physical illness is in no sense new. That people may be driven by adversity into decline is a familiar theme in literature. Strictly speaking, the phenomenon is distinct from that of psychosomatic illness such as Freud's well-documented cases of hysterical paralysis in which, in Freudian terms, the illness is a kind of talisman for the emotional disturbance. Instead, the physical consequences of emotional shock may become manifest in normal people even if they are more spectacular among those with an underlying emotional disturbance.

Over two decades, Professor G.W. Brown of Bedford College, University of London, has been collecting evidence that what he calls life-events (imprisonment, relocation or personal bankruptcy, for example) may provoke illness in outwardly normal people. The speed with which a person's death will follow that of his or her spouse is the most familiar occurrence of this kind. The pattern is familiar, but the mechanism is unknown.

That, at least, has been the state of affairs until quite recently. Now, as some of the new generation of medical students know perhaps too well, there is emerging a speciality called psychoimmunology — a means of explaining such phenomena as the increased risk of death on bereavement in terms of the disturbance caused to the immune system in the wake of emotional shock or deprivation. The difficulty, for the rest of us, is that of knowing just what weight to give to these accounts.

That there should be a functional connection between the central nervous system and the immune system is not in itself surprising. In animals, neurophysiologists now have a lot to say about the way in which the brain controls the system of locomotion, while the regulation of the reproductive system in mammals by means of the peptide hormones involved in the regulation of the pituitary gland by the hypothalamus is being understood in ever finer detail.

A kind of connection between the central nervous system and the immune system is made plausible by several unconnected observations, not the least of which is that some types of the lymphocytes involved in the body's immune response to, say, bacterial infections are found to carry receptors which recognize simple peptide hormones also found in the brain.

Some of the connections have been reviewed by David Maclean and Seymour Reichlin (*Psychoneuroimmunology* **12**, 475; 1981), and can plainly take several different forms. Maclean and Reichlin offer the interaction of the hypothalamus and the pituitary as the most interesting source of materials that may modify immune function. Some possible interactions are direct, as with the pituitary hormone that appears directly to stimulate the development of cells in the thymus, the organ in which T-cells become recognizably different from cells that produce antibodies. But the best-known routes by which pituitary hormones may affect the immune system are indirect, involving the stimulation of the adrenal cortex by hormones such as adrenocorticotropic hormone.

This imbalance is unlikely to persist for long. As techniques improve for distinguishing between T-cells in different stages of their maturation and for sustaining them in culture, there has naturally been an upsurge of interest in the measurement of response by lymphocytes to hormones of various kinds. It seems to be established that the steroid hormones of the adrenal cortex more markedly stimulate lymphocytes at early rather than late stages in their differentiation, which may suggest how the composition of the circulating lymphocytes may be controlled by peptide hormones.

And then, it seems, some peptide hormones stimulate T-cells to produce lymphokines (such as interleukin-2 but also interferon) and others have the opposite effect. The more radical psychoimmunologists talk as if there is no state of mind which is not faithfully reflected by a state of the immune system.

Others go further. J. Edwin Blalock of the University of Texas at Galveston, writing in the *Journal of Immunology* in March (**132**, 1067; 1984) under the title "The immune system as a sensory organ", argues that the interaction between the central nervous system and the immune system must be reciprocal, with peptide hormones of the pituitary and lymphokines secreted by lymphocytes having similar functions in the blood and with antigenic stimuli such as different kinds of bacterial infections producing physiological and even behavioural changes in the infected animal. He does not quite say that the emotional consequences of measles and tuberculosis infections should be distinguishable — but of course, they are.

The other line of inquiry that has helped put psychoimmunology on its feet are experiments with whole animals. In many ways, these are adjuncts of the classical investigations of the effects of stress on the system of adrenal hormones and thus on blood pressure, heart rate and so on.

In one typical investigation (Laudenslager, M.L. *et al. Science* **221**, 568; 1983), groups of a dozen rats were given electric shocks of two kinds, and the sensitivity of their lymphocytes to artificially provoked cell division by the materials called mitogens assessed. The more seriously stressed rats were found to have the least easily stimulated lymphocytes at the end of the experiment.

Surprisingly, very similar investigations can be mounted with people. Thus S.J. Schleifer *et al.* have tackled directly the question of the immunological consequences of bereavement by means of a prospective study among men whose wives had been found to have breast cancer. Those who were eventually widowed have been reported (*J. Am. med. Ass.* **250**, 374; 1984) to have had circulating lymphocytes less responsive to the effect of mitogens, just like the rats given electric shocks.

Investigations such as these, while time-consuming and costly, at least have the merit of being practicable and, once mounted, easy to interpret. The snag is that statistically significant samples are accumulated only slowly, and at a high cost.

Why, in these circumstances, does there persist a stout band of near-sceptics convinced that too much is being made, at this stage, of the explanatory value of psychoimmunology? There are several reasons, not the least of which is that very similar lines of argument, more accurately, hypotheses, have been used within living memory speciously to suggest links between a person's chance of developing cancer and his or her state of mind.

Second, because knowledge of T-cells and their function is growing so quickly, it is necessarily difficult to design systems for assaying the effects of hormones, or of states of mind, on lymphocytes that are reproducible and significant.

Third, one rather crucial question seems to have been left for too long aside. If it should be that a person's state of mind, say grief, may affect the quality of his immune system, how does it then transpire that he or she will be more likely to die of heart attack or stroke or even in a road accident? In short, the explanation is likely to be part of a more complicated tale. **John Maddox**

Evolution

Palaeontology at the high table

from John Maynard Smith

THE Tanner lectures, recently delivered by Stephen J. Gould of Harvard University, and followed by a panel discussion*, provide an opportunity to assess the current contribution of palaeontology to evolutionary theory. It might be supposed that this contribution would be crucial, but, at least until recently, that has not been so. The palaeontologist G.G. Simpson was one of the main architects of the 'modern synthesis' that emerged in the 1940s, but his role was to show that the facts of palaeontology were consistent with the mechanisms of natural selection and geographical speciation proposed by the neontologists (a term used by palaeontologists to describe the rest of us), rather than to propose novel mechanisms of his own. Since that time, the attitude of population geneticists to any palaeontologist rash enough to offer a contribution to evolutionary theory has been to tell him to go away and find another fossil, and not to bother the grownups.

In the last ten years, however, this situation has been changed by the work of a group of palaeontologists, of whom Gould has been a leading figure. In his lectures, he stressed two theoretical modifications to the Darwinian scheme — 'punctuated equilibria' and a hierarchical view of evolution. Punctuational theory holds that most evolutionary change occurs when lineages split — that is, when a single species gives rise to two. Between such events, species remain morphologically unchanged, often for millions of years: they remain in 'stasis'. In itself, the theory says nothing about the mechanism of the changes when they do occur, other than that they are rapid in geological terms: they could still be slow to a geneticist, and brought about by the familiar process of natural selection. As J.S. Jones (University College, London) remarked in an earlier discussion, one man's punctuation is another man's gradualism.

Little was said in Cambridge about the empirical evidence for punctuation. Gould treated it as a fact the whole world knows: as something proved by Aunt Jobisca's theorem. As an outsider, I am persuaded that morphological evolution proceeds at very different rates at different times, but can see little evidence that rapid change is necessarily associated with the splitting of lineages (although one would expect this often to be the case, when part of a species enters a new ecological niche). What is new is the emphasis on stasis. As David Wake (University of California, Berkeley) pointed out during the discussion, the existence today of pairs of species which are morphologically indistinguishable, or almost so, but whose proteins have diverged sufficiently to suggest that they have been separate for millions of years, supports the reality of stasis. Stasis, then, is a phenomenon that calls for an explanation.

Geneticists and palaeontologists tend to differ in the explanations they prefer. Population geneticists argue that if a species does not change, this is because it is subject to 'normalizing selection' — that is, selection that eliminates the extreme phenotypes and favours the norm. They have two main reasons for this belief. First, if directional selection is applied to almost any characteristic, in nature or in the laboratory, the population will change. Second, most species with a wide geographical range do vary in structure and behaviour, sometimes to such an extent that populations from different regions would be regarded as different species if they were not connected by a series of intermediate forms. (In case anyone supposes that membership of a species is decided unambiguously by hybridization, it is the case that different species often produce fertile hybrids, and populations of the same 'species' often prove, on investigation, to produce sterile or inviable hybrids.)

In reply, Gould asks how it could possibly be the case that normalizing selection could favour the same phenotypes over long periods, during which the environment may change drastically. Instead, he proposes a concept of species stability arising from developmental constraints. The constancy of a species would thus resemble the constancy of a chemical element: it would represent a stable state of matter, which can be changed only by an unusual event. C.H. Waddington's idea of 'canalization' has been quoted in support of this view. Waddington did indeed point out that the typical 'wild-type' morphology of a species is usually well buffered against disturbance during development, whereas the phenotypes of individuals with a given mutation are highly variable between individuals. However, for Waddington, the uniformity of the wild type was itself the product of normalizing selection, and not a manifestation of an intrinsically stable state.

Hierarchies

The debate about stasis and punctuation will no doubt continue. Gould's second thesis concerned the hierarchical structure of evolution. Darwin, he argued, thought of natural selection as favouring some individual organisms at the expense of others. However, selection, and also chance, can be effective at two other levels, namely the gene and the species. At the level of the gene, we now know that there are processes (gene conversion, unequal crossing-over, transposition) that enable genes to multiply out of phase with the organisms in which they find themselves. It follows that a gene can increase in frequency by virtue of its ability to multiply horizontally within an individual, and not only by virtue of its effects on the individual's phenotype.

Two points were made about this level of selection during the discussion. John Fincham (Cambridge University) pointed out that since transposons are in effect parasites, we can expect them to evolve 'self-restraint', as some parasites do: it does not pay to kill the goose that will transmit you to future generations. A more fundamental disagreement was raised by Gabriel Dover's (Cambridge University) claims for 'molecular drive' — a portmanteau term for the three processes listed above. I may give an unfair account of this disagreement, because I was one of the protagonists. Dover asserted that there is nothing that natural selection can do that cannot be done by molecular drive. I argued in reply that this is to overlook the fact that natural selection can generate highly improbable adaptations at the organismic level, whereas molecular drive cannot. As I see it, Dover's view would throw out the Darwinian baby with the bathwater.

Species selection

Palaeontologists can contribute little to this debate, but have a lot to say about the level of species selection. The concepts can best be explained by some examples. First, during the Cretaceous, the Volute gastropods gradually replaced their competitors. A plausible explanation is that Volute development did not involve a stage of mobile planktonic larvae, whereas the development of their competitors did. As a result, geographical speciation was more frequent among Volutes, and the number of species increased. In effect, Volute species had a higher 'birth rate'. If this explanation is correct, it applies the concept of natural selection, but replaces individuals by species as the units selected.

Now consider a second example, the mammalian secondary palate. This is a structure that enables a mammal to breathe and chew at the same time. Gould would agree that such a structure (together with associated changes in teeth, jaw muscles and articulation) could arise only by natural selection at the level of individuals. Suppose, however, that mammalian species came into competition with reptiles lacking these adaptations. If the mammals outcompeted the reptiles because they could chew better, then mammalian species would replace reptilian ones. However, Gould would not call this species selection, because the success of the mammals would depend on something individual animals do (chew) and not on something species do: in contrast, in the Volute example, speciation is something species and not individuals do.

* The Tanner Lectures were delivered in Cambridge under the auspices of Clare Hall, 30 April–2 May 1984.

There is a third scenario. For example, at the end of the Cretaceous the Dinosaurs became extinct, whereas the mammals survived and radiated. I do not know why this was so, but let us suppose that the mammals survived because they are homoiotherms, and that their ability to chew had nothing to do with it. It would still be true that the Cretaceous extinctions led to an increase in the proportion of species with secondary palates, but not because of any selection for the palate itself. This is what Elizabeth Vrba has called the 'effect hypothesis'. It is an analogue, at the level of organs, of the process of 'hitch-hiking' at the level of genes.

The hierarchical view of evolution, then, is that processes of selection and stochastic drift go on at the level of genes and of species, as well as of individuals. As an old-fashioned proponent of the modern synthesis, I have no difficulty in accepting this, so long as no one expects me to believe that adaptations of individuals can be explained by molecular drive, and so long as the concept of species selection is confined to qualities, such as speciation rate and evolutionary rate, that are properties of species and not of individuals. However, there remains plenty of room for disagreement about the relative importance of these various levels, or — what amounts to the same thing — about the relative effectiveness of selection at different levels.

In from the cold

This brings me to what I see as the greatest impact that palaeontology is having on the way we see the mechanisms of evolution. We have been familiar for a long time with the dramatic disappearance of the Dinosaurs at the end of the Cretaceous. It is now apparent that massive extinctions, involving many different taxa, have been a repeated feature of evolution. Adolf Seilacher (Tubingen University) and Anthony Hallam (Birmingham University), the two palaeontologists on the panel, agreed with Gould on this, although there was disagreement about whether these events have been periodic or irregular, and whether they are caused by extraterrestrial events (meteorites, asteroids) or by terrestrial ones (Hallam, for example, emphasizes the role of changes in the area of the continental shelf caused by continental drift — see *Nature* **308**, 686; 1984). The impact of these extinctions is not random; in any given event, some taxa are more affected than others: Seilacher stressed the need for a quantitative study of this, to replace the somewhat anecdotal picture we now have.

In addition to the problem of their causation (which at present seems to be a problem for geologists and astronomers, although Seilacher did not rule out the possibility that some extinctions had biotic causes), these extinctions raise questions for evolutionary biologists. Is it possible that evolutionary change would slow down and stop in the absence of changes in the physical environment? As Manfred Eigen has pointed out, the simplest evolving systems (populations of RNA molecules in test tubes) reach a global optimum and then stop. Are extinctions, then, a necessary motive force of evolution? A second question concerns the relation between extinction and radiation. Ecologists tend to see nature as dominated by competition. They would therefore expect the extinction of one species, or group of species, to be caused by competition from another taxon. Most palaeontologists read the fossil record differently. The Dinosaurs, they believe, became extinct for reasons that had little to do with competition from the mammals. Only subsequently did the mammals, which had been around for as long as the Dinosaurs, radiate to fill the empty space. The same general pattern, they think, has held for other major taxonomic replacements. Not all palaeontologists would agree, but I think this is the majority view. I find it surprising: I would have expected a major cause of extinction to be competition from other taxa.

The Tanner lectures were an entertaining and stimulating occasion. The palaeontologists have too long been missing from the high table. Welcome back. □

Malarial immunity

Indonesian and Sudanese style

from F.E.G. Cox

RECOVERY from malaria is accompanied by the production of antibodies that block the entry of merozoites — the infective stage of the *Plasmodium* parasite — into red blood cells[1]. Alternatively, it can be accompanied by a mechanism that kills the developing parasites within the red blood cell. This phenomenon has been known since 1944, when the Taliaferros noted the appearance of disintegrating forms, 'crisis forms', of a simian malaria parasite, *Plasmodium brasilianum*, in the red cells of recovering monkeys[2], but received little attention until it became clear that crisis forms are associated with recovery from a number of different *Plasmodium* infections in laboratory animals[3]. Although crisis forms are not apparent in the peripheral blood of patients with malignant tertian malaria caused by *Plasmodium falciparum* (because the developing stages of the parasite disappear from the circulating blood), they can regularly be detected *in vitro* both visually and by a test in which the incorporation of radiolabelled hypoxanthine into growing parasites within the red cell is measured[4]. That test has recently enabled James Jensen and his colleagues to show that in the Sudan, and probably elsewhere, intraerythrocyte killing predominates over merozoite blocking as a means of defense against the parasite[5-7]. These observations should completely alter our concepts of the development of vaccines against the blood-borne forms of *Plasmodium falciparum*.

Jensen and his colleagues collected sera from some 300 people living in three regions of the Sudan and tested their ability both to block the invasion of red cells by merozoites and to induce crisis forms in erythrocytes containing 'ring stage' parasites. The population could be divided into those who had experience of serious attacks of malaria, of mild malaria or no experience of malaria[6]. The clinical status could not be correlated with the presence of merozoite-blocking antibodies but was correlated with the ability of the serum to induce crisis forms. The greatest number of crisis forms was induced by sera from the group with no experience of malaria and hence with the greatest immunity to the disease. The serum factor that causes parasites to die in the red blood cells is not antibody because antibodies on the merozoites are sloughed off as the parasites enter the red cells; moreover, activity is not lost with the removal of immunoglobulin[5]. Jensen and his colleagues call the factor 'crisis-form factor' (CFF)[6].

In the Sudan, then, clinical immunity to malaria can be correlated with the presence of CFF in the serum. But what of other parts of the world? Jensen *et al.* have now shown that Indonesian sera do not induce crisis forms *in vitro*[7]. In order to make a direct comparison, the earlier Sudanese studies were repeated with sera from an area where the prevalence of malaria was similar to that in Flores, where the Indonesian study was carried out. Overall, Sudanese sera have abundant CFF and little merozoite-blocking antibody whereas Indonesian sera lack CFF, and their anti-parasitic activity, where present, is associated with merozoite-blocking antibody. This indicates that genetic differences may be important in determining whether antibody or non-antibody factors predominate in immunity to human malaria.

These experiments are of great importance and should significantly alter our concepts of an antimalarial vaccine. It is conventional to identify and isolate blood-stage antigens of the parasite by means of monoclonal antibodies and immune sera[8]. Such techniques may well lead to a vaccine that elicits a high and specific antibody response. But will this be protective when sera with antibody titres greater than 1:10,000 have little merozoite-blocking effect[7]? And if merozoite-blocking is of

relatively little importance in natural immunity in Sudan, could it be the basis of an effective vaccine there? If genetic differences between the populations at risk have to be taken into account in malaria vaccine development, it will greatly complicate the task.

What is CFF? The short answer is that we do not know. As long ago as 1953, Trager and McGhee identified a factor in the sera of birds immune to malaria that inhibited infection by Rous sarcoma virus[9]. From this has arisen the possibility that CFF is related to the ill-defined tumour necrosis factor[10,11]. Alternatively, it may be related to certain reactive oxygen intermediates that bring about the occurrence of crisis forms both *in vivo* and *in vitro*[12,13]. However reactive oxygen intermediates are probably too short-lived to produce directly the effects recorded by Jensen *et al.*, although they could be involved in reactions with lipids to produce toxic substances such as aldehydes[14].

What must happen now is a switch of attention away from *Plasmodium* antigens that elicit the production of antibodies to those that elicit CFF. Since CFF is probably a product of macrophages, these cells and the T cells that activate them require much more attention. At a very basic level, however, we now know that CFF kills malaria parasites and thus, if characterized, could be used to treat the rapidly increasing number of drug-resistant cases for which there is no obvious alternative treatment. Further studies of CFF might also provide clues to the development of new antimalarial drugs. □

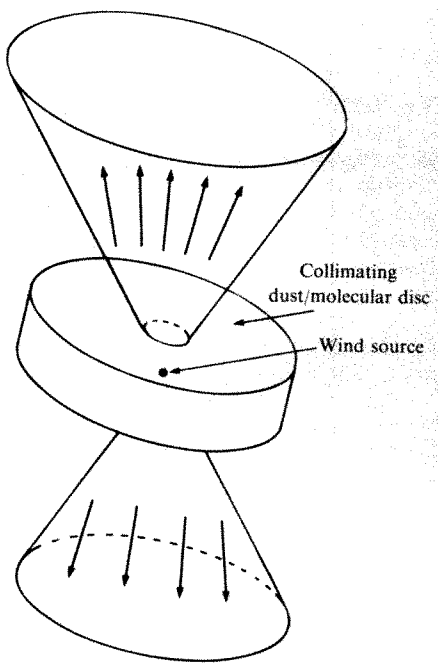
100 years ago

THE *Bolletino* of the Italian Geographical Society for May contains a brief account of Signor Maurizio Buonfanti's late expedition across North Africa. After some trips to Yakoba and other little-known parts of Sokoto, he made his way through Gando to the Niger at Say, about midway between Timbuktu and the Binue confluence. Here he turned north, and for the first time *ascended* the Niger as far as Timbuktu. This feat, hitherto supposed to be impossible, was performed *in the dry season*, and the problem thus successfully solved possesses considerable geographical and commercial importance in connection with the attempts now being made to establish regular lines of water communication between Western and Central Sudan and the Gulf of Guinea. From *Nature* **30**, 131, 5 June 1884.

Astronomy



High-velocity winds in Orion

from Ben Zuckerman

THE biggest surprise to emerge from a decade of observational study of the formation of stars has been the realization that this process is accompanied by massive outflowing winds. The winds, which can be sporadic, are millions of times stronger than the solar wind and are generated by most, perhaps all, young stars either shortly before or, more probably, shortly after they initiate the burning of hydrogen into helium in their interior. Since it is natural to think of star formation as a process of collapse, or infall, the ubiquitous occurrence of an accompanying outflow comes as a bit of a shock. Now D.J. Axon and K. Taylor have described new optical spectra indicating very high-velocity winds in the most famous region of star formation in the heavens, the Orion Nebula (*Mon. Not. R. astr. Soc.* **207**, 241; 1984). Their spectra point towards the existence of a biconical pattern of outflow and suggest the presence of a substantial disc of molecular gas and dust grains close to a putative stellar source of excitation, located in the giant molecular cloud behind the nebula.

As a result of isolating the 6,300 Å wavelength forbidden transition of neutral oxygen, which is prominent in shock-excited regions but relatively weak in photoionized gaseous nebula such as the Orion Nebula, Axon and Taylor discovered a 'family' of six shock-excited objects which, in the plane of the sky, are located near a group of strong infrared-continuum sources discovered in the 1960s. The latter are believed to constitute a very young, but highly obscured, star cluster behind the Orion Nebula. The oxygen atoms display a very wide range of line-of-sight velocities extending from near 0 km s^{-1} (the velocity of the molecular cloud) to an approach velocity of nearly 400 km s^{-1}. When projection and other effects are taken into account, the implied wind velocities are of the order of 1,000 km s^{-1} — similar to that of winds from the most massive main-sequence stars in our Galaxy.

Taking into account previous observations of Orion, primarily at infrared and microwave frequencies, Axon and Taylor conclude that the most plausible model of the region is one in which a biconical protostellar wind originates from one (or more) of the massive young stars that are embedded in the molecular cloud, as in the figure. Although the star itself must be obscured from our view by an optically thick disc that lies, presumably, in its equatorial plane, the wind can escape from the polar regions. In their model, the shock-excited objects, detected by neutral oxygen emissions, are the result of the impact between the winds and gas blobs ('knots') located at the front face of the molecular cloud, just behind the Orion Nebula itself.

Model of biconical protostellar wind in the Orion Nebula. (From Mon. Not. R. astr. Soc. **207**, 246; 1984.)

These results bear on more general questions related to star formation and massive winds. Observations of many other regions of star formation indicate that bipolar or biconical outflow is the rule rather than the exception. Orion has now been reasonably securely added to this class. If the collimation is due to a disc of gas and dust located near the stars, as Axon and Taylor, like many others before them, suggest, then it is possible that at least the raw material necessary to make planets can be found in the vicinity of most young stars. Since not a single planet has been identified with certainty outside our Solar System, the implied ubiquitous existence of this raw material is of considerable interest.

Material which may be distributed in the form of a small disc with dimensions only about three times that our Solar System has very recently been seen directly (via scattered light at 2 μm wavelength) near the very young star, HL Tauri, by two different teams (S. Beckwith, B. Zuckerman, M. Skrutskie and H.M. Dyck, and S. Strom and G. Grasdalen, *Astrophys. J.*, in the press). However, it still remains to be shown how frequently a gaseous disc, as opposed to some other physical mechanism such as a magnetic field, is actually responsible for collimation of the winds that accompany star formation. □

Protein structure

From *Bacillus* to rabbit

from Roger H. Pain

ON page 467 of this issue, Poorman *et al.* suggest a three-dimensional structure, complete with binding sites for substrates, activators and inhibitors, for a mammalian multisubunit enzyme, largely on the basis of the amino acid sequence of the enzyme and the crystallographic structure of the equivalent, but smaller, enzyme from a bacterium. Their report is of intrinsic interest to the protein chemist since it suggests a model which is testable by experiment. It is also of broader interest because it illustrates both the confidence with which biologists now assert that protein conformation is selected for and preserved during evolutionary processes and the way in which speculation on protein structure can be in order.

The enzyme is phosphofructokinase (PFK). It operates in the glycolytic pathway which is the means, common to all living organisms, of abstracting useful energy from the oxidation of glucose. PFK is particularly important because its activity can be modulated to control the rate of oxidation of glucose in response to energy demand in the cell. The reaction catalysed is the phosphorylation of fructose 6-phosphate by ATP to yield fructose 1,6-diphosphate and ADP. Insofar as they are all activated by raised concentrations of ADP, the enzymes from all species behave similarly. The greater sophistication of higher organisms, however, is reflected by the fact that their PFK is also activated by fructose 1,6-diphosphate and is inhibited by ATP. Moreover, their PFK is inhibited by citrate, allowing feedback control from the citric acid cycle. The greater complexity of the eukaryotic enzyme, requiring additional specific binding sites, is reflected in a molecular weight for each of its four identical subunits that is approximately double that of the prokaryotic enzyme.

To date, the only three-dimensional structure of PFK to have been determined is that of the prokaryote, *Bacillus stearothermophilus*. The structure of a eukaryotic PFK, the rabbit enzyme being the most studied, is needed in order to understand the more sophisticated mechanisms by which it is controlled. Poorman and colleagues have attempted to provide this, based mainly on comparison of amino acid sequences. They have determined the sequence of rabbit PFK and found that the subunit sequence falls into two similar halves, with more than 30 per cent of their amino acids being identical. Comparison of the two halves with the sequence of *B. stearothermophilus* PFK shows that 34 per cent of the amino acids of the carboxy-terminal half, and 44 per cent of the amino-terminal half, of the rabbit enzyme are identical to those in the bacterial enzyme.

This is taken to signify that the eukaryotic enzyme is the result of a duplication of the prokaryotic gene, with subsequent independent mutation within certain constraints. A further unknown mechanism must account for the additional 30 amino acids which join the non-identical twin domains of the rabbit enzyme. By packing four such 'double-bacillus' subunits together, with due regard to symmetry and the location of ligand-binding sites, Poorman *et al.* have constructed their three-dimensional model of rabbit PFK.

By straightforward extrapolation from the bacterial enzyme, rabbit PFK would be expected to contain 8 substrate binding sites and 8 ADP effector sites. Sequence comparison has led to identification of the four fructose 6-phosphate binding sites that are known to exist in rabbit PFK; sequences for the other four are significantly altered by mutation and are postulated to be fructose 1,6-diphosphate activation sites. It is also assumed that four ADP effector sites have been mutated to form ATP inhibitory sites.

These arguments rest on two generalizations. First, that such close relationships between amino acid sequences are the result of the organisms being at points on an evolutionary tree separated by a divergent process. Second, it is assumed that despite appreciable changes in amino acid sequence and despite the fact that certain amino acid substitutions can lead to a dramatic destabilization of three-dimensional conformation, the two sequences will fold into similar conformations. The 'code' relating sequence to conformation is known to be degenerate. The assumption is that selection operates on the one hand to keep the changes in sequence within these limits of degeneracy so that conformation does not vary significantly and, on the other hand, to retain certain active sites and to allow others to be modified so as to lead to more advantageous catalytic activity. This emphasis on the conservation of conformation is intriguing and the reasons for it are by no means certain. It is fascinating to see how these generalizations, only relatively recently established by comparing known sequences and conformations, are now being used in reverse to predict conformations from sequence — in this instance, of rabbit PFK. □

Bacterial motion

Progress in flagellation

from Michael Spencer

IT is now more than ten years since the electrifying announcement that bacterial flagella actually rotate rather than propagate helical waves like larger motile organelles. The discovery was all the more surprising because it was by then becoming clear that flagella could adopt a number of different waveforms by internal rearrangement of the flagellin monomers, and an extension of this to a mechanism of active wave propagation did not require any dramatic act of faith.

From that watershed in knowledge have flowed two quite separate streams of thought. From recent publications, however, it now looks as if these independent streams, which have followed their courses for so long without meeting, are on the point of converging. Prominent in one stream is the school of Sho Asakura, which for at least two decades has continued a series of elegant demonstrations of the polymorphic nature of flagellar structure. These studies have been complemented by the ingenious theoretical predictions of a structural engineer, C.R. Calladine, and have led to satisfying explanations of the transitions that enable bacteria to change direction. The other stream of research has concentrated on the morphology and dynamics of the basal body that constitutes the flagellar motor; this has involved groups led by Howard C. Berg and others. They have confirmed that the motor is powered not directly by ATP but by protons, so that an electrical potential or a *p*H gradient across the membrane is sufficient to generate rotation.

Interest has been growing recently in the short region linking the basal body to the flagellum; it is normally sharply curved (and called the 'hook') and helps the larger-scale helix of the flagellar filament to insert into the motor in a direction perpendicular to the cell wall. It may also have enough flexibility to allow flagella to group into bundles. The structure of isolated hooks was determined a few years ago by Wagenknecht *et al.* (*J. molec. Biol.* **151**, 439; 1981 and **162**, 69; 1982). Although the monomers form a tubular structure and are packed in a very similar way to those in flagella, there are deep grooves in the surface of the hook that could facilitate bending without unduly reducing the ability to transmit a torque.

Some interesting new findings have now been published by Kato, Okamoto and

Asakura (*J. molec. Biol.* **173**, 463; 1984). They studied a mutant hook, the 'polyhook', which is much longer than in the wild type and can adopt either a straight form or a helical one; in the latter the amplitude and pitch are much smaller than those of the flagellar filament. Kato *et al.* now have evidence for both left-handed and right-handed helices, and suggest that the hook undergoes transitions between helical senses in the same way as the flagellar filament.

Like many discoveries, this raises more questions than it answers. The first surprise is that the 'normal' form of the hook (at neutral *p*H) follows a right-handed helix, whereas the rest of the flagellum is left-handed in the species studied — *Escherichia coli* and *Salmonella typhimurium*. This means that when the motor starts up in its normal sense of rotation, which is counterclockwise when looking towards the base, the torque transmitted to the hook is such as to unwind its helix (readers who feel dizzy when trying to visualize this are referred to Fig. 1*a*). In these conditions flagella tend to flip into an alternative helix of opposite sense.

Kato *et al.* speculate that when the motor starts up, the resulting stress may transform the hook into the alternative left-handed type, which would then have the same sense as the main flagellar filament. This raises intriguing questions about what happens during 'tumbling' or 'twiddling', the process by which bacteria periodically change direction so as to move up a favourable gradient (for a review see Berg *Scient. Am.* **233**, 36; 1975). At the start of a tumble the direction of motor rotation reverses and bundles of flagella that previously rotated in phase become jammed; the stress induces a change of sense in the flagella which then fly apart (Macnab and Ornston *J. molec. Biol.* **112**, 1; 1977). If the hook is held in a left-handed form during normal motion, presumably it reverts to right-handed when the motor reverses. Is this an essential step in the transformation of the filament?

A second question raised by the new results is whether the hook transformation can be explained on the model proposed for flagella by Calladine (*J. theor. Biol.* **57**, 469; 1976 and *J. molec. Biol.* **118**, 457; 1978). This model presumes the existence of 'protofilaments' or strings of monomers which may (through cooperative changes in monomer conformation) adopt either a 'long' or a 'short' state. If the protofilaments run round the tubular structure at an angle to its axis, the existence of two classes of protofilament in the same flagellum will cause it to coil into a helix (Fig. 1*b*). The parameters of the helix depend on the relative population of the two states.

The model predicts that in going from one state to another the 'twist' of the protofilaments will change, and that between a left-handed and a right-handed helix the 'twist angle' changes sign. In flagella the twist angle varies between −3° and +8°, which does not demand a substantial change in monomer packing. In the polyhook, however, the observed helical waveforms (from which twist angle was obtained indirectly) would require a range of about −50° to +20°. Even more puzzling, the protofilaments appear to be identified not with the 11 rows of contiguous monomers that fulfil this function in the flagellar filament, but with a set of '16-start' helices joining monomers that are not in close contact with each other.

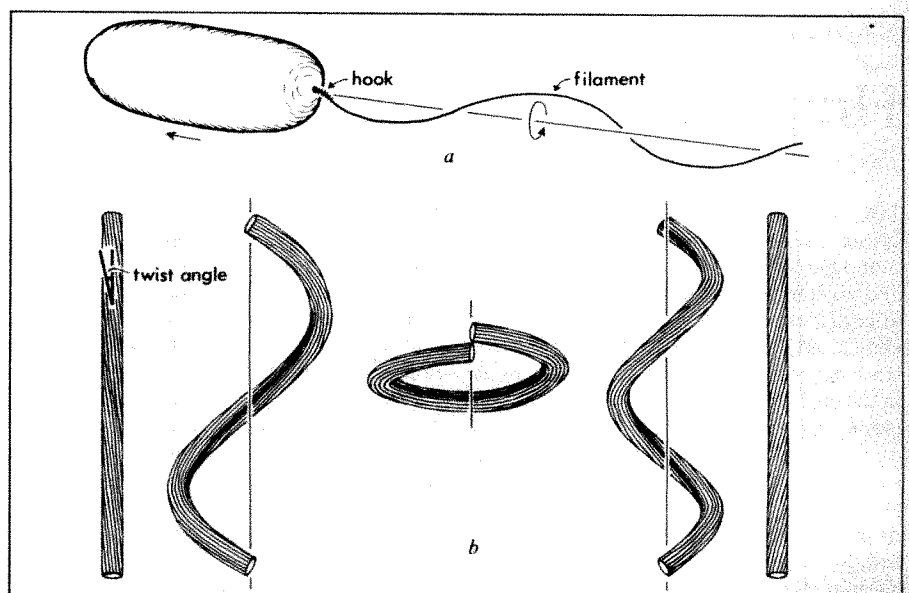

Fig. 1. *a*, Normal mode of forward propulsion by a flagellum for *E. coli* and *S. typhimurium*. *b*, Polymorphic forms of flagella obtainable by varying the twist angle (exaggerated here). The shortest protofilament (heavy line) always runs on the inside of the structure; in the two straight forms all protofilaments have the same length.

Kato *et al.* are suitably cautious about this conclusion, and mention the possibility that preparation for microscopy may have deformed the polyhooks; the matter will have to await direct observation of twist angles by high-resolution imaging of the surface lattice. A possibility not discussed in the paper is that in the hook the basic structure is invariable, as suggested by Wagenknecht *et al.* (see above), and that left-handed and right-handed forms involve protofilaments joining two different sets of points in the helical net. Neither of these needs necessarily be the set of 16-start helices discussed by the authors.

By a curious coincidence, a paper by Block and Berg on page 470 of this issue gives fresh significance to the old observation that certain components of the basal body 'motor' have a 16-fold symmetry. These authors have been studying a mutant of *E. coli* whose flagella are intact but paralysed unless the missing gene product is supplied. The appropriate gene under the control of the *lac* promoter was arranged to be carried into the bacteria as part of a transducing phage; the gene product was synthesized on addition of a *lac* inducer. When carried out with bacteria tethered to a glass surface by a single flagellum, the cells began to spin with increasing speed a few minutes after the addition of inducer.

The most interesting feature of the results is that the speed of rotation increased (or occasionally decreased) in discrete steps; at first there was a doubling of speed, which was followed by increases to speeds that were all multiples of the initial value for a given cell. The initial speed varied from cell to cell, presumably because of variations in the viscous drag on the cell body. Discrete steps could not be resolved beyond about the sixth, and most cells came off the glass or stuck to it before reaching their terminal speed. However, from one cell that continued rotating up to maximum speed and from other experiments on wild-type cells, Block and Berg calculate that the maximum number of steps is close to the magic number of 16. Their interpretation of this behaviour is that the gene product released by the *lac* inducer diffuses to the vicinity of the flagellar motor, which contains a number of independent force-generating units each requiring the gene product.

Block and Berg calculate that about 65 protons pass through a single force generator in one revolution, if the efficiency of the machine is unity — an assumption that may raise eyebrows among muscle biochemists. What might also attract their attention is that the torque per generator is calculated to be about 3×10^{-12} dyne cm; assuming that the generators act at a radius of 10 nm, one can infer that the tangential force per generator is about 20 times the average force generated by a muscle cross-bridge. In that sense bacteria seem to have a better design than muscle, and workers on flagella may have the more tractable problem. They still, however, share with devotees of muscle the need to find out how force is generated at the molecular level. □

Neurology

Hopes of central repair

from Jeffrey S. Nye

THE fact that the adult central nervous system cannot be repaired after injury and that neurological deficits are permanent and unchanging was challenged recently at a conference* which brought together clinical and basic neuroscientists who are studying regenerative and repair processes in the central nervous system. The meeting made clear that clues from animal models of degenerative disease, as well as basic studies of regeneration in the nervous system, are increasing our understanding of neurodegenerative disease. Moreover, a radical change in the way some of the diseases are treated may be in the offing.

Controversy continues about the extent and importance of neurogenesis in adulthood [1]. Classically, only during embryonic life do neuronal precursor cells multiply. They then migrate from the ependymal or subependymal zones to their ultimate destination, and only there differentiate into neurones or glia. In fish and birds, however, the evidence for neurogenesis in adulthood is clear. Fernando Nottebohm (Rockefeller University) has shown that some avian species destroy and regenerate each year the neurones in certain forebrain nuclei [2]. In these nuclei, which subserve song production and perception, the acquisition and loss of neurones precede the bird's yearly acquisition and loss of song [3]. Thus neurogenesis serves an adaptive function in the life of songbirds. In the dentate gyrus and the olfactory bulb of adult rats, select populations of cells are born which are clearly neurones and not glia, in view of the presence of synapses and neurochemical markers [4,5].

Neuronal plasticity does not depend exclusively on the formation of new neurones. In primates, for example, all neurogenesis is complete soon after birth, but learning continues throughout adulthood. Pasko Rakic and colleagues (Yale University) argue that each neuronal population is born within its own discrete span of time during embryogenesis, some continuing into early infancy [6]. Despite extensive searching, no neurones born after this period have been found in primates, with the sole exception of the olfactory neurones, which are renewed throughout the lifetime of the organism [7]. Restoration of the capacity for neurogenesis in adult primates continues to be an attractive challenge to many neuroscientists.

Instead of growing new neurones, adult primates adapt by forming new synapses (synaptogenesis) and modifying old ones. What stimulates these adaptive processes remains an open question. In a model system using rats, Carl Cotman has shown that damage to neurones innervating the hippocampus will stimulate surviving neurones to increase the number of synapses they form with the hippocampus [8]. This reactive synaptogenesis may also be important for recovery of function after damage to neurones in aging and in neurodegenerative disease. In the aging rat, the rate of synaptogenesis after injury slows, but the same final number of synapses is reached as in younger animals. Quantitative similarity in the number of synapses, however, does not explain well known differences between the responses of old and young rats to brain damage. Indeed, Cotman has found decreases in the number of synapses contralateral to the injury in the hippocampus of old rats. He also finds differences in glial secretion of neuronal trophic factors in old versus young rats [9]. These findings may offer a possible mechanism for the poor recovery of old animals after injury.

A highlight of the meeting was the presentation by three groups of the startling results of their studies of neural tissue grafts. Albert Aquayo (Montreal General Hospital) and his group have been studying axonal growth after injury to the central nervous system [10]. In contrast to peripheral nerves, central neurones do not regrow axons past an injury; normally, they are prevented from doing so by astrocytes and oligodendroglia. However, when peripheral nerve sheaths, containing Schwann cells, are grafted next to the site of such an injury, some central neurones will extend axons as far as 3 cm through them. But when they reach the end of the peripheral nerve graft and re-enter damaged central nervous system, they stop growing and make no functional connections. Unfortunately, this impediment must be overcome before grafts of peripheral nerve can be used to repair damaged central nervous tissues.

Another approach to restore function after injury or in neurodegenerative disease requires grafts of neurones similar to those which are damaged or missing. Pioneering work has demonstrated that intracerebral grafts will establish reciprocal synapses with surrounding nervous tissue [11]. Functional recovery, however, requires that the grafted neurones establish a network of connectivity similar to that found in undamaged brain. The stringency of this requirement may depend on the site of damage. Might fetal cells, which are developmentally ready to send out processes and establish connections, retain these abilities outside their normal environment?

In a number of successful experiments, Lars Olson and colleagues (Karolinska Institute) have demonstrated that fetal neurones will survive grafting into the anterior chamber of the eye of a rat [12]. Moreover, neurones from the fetal substantia nigra implanted into the eye will generate the same firing pattern that they do *in situ*. When implanted adjacent to a fragment of striatum derived from an adult rat, fetal nigral cells innervate and establish functional connections with it.

In a similar series of experiments, the Lund group, led by Anders Bjorklund, has shown that injected fetal neurones from the septal nuclei will innervate a denervated hippocampus [13]. The implanted cells elaborate a pattern of cholinergic projections remarkably similar to that of the intact hippocampus. Even more astonishing, the grafts enable rats that have lost their cognitive abilities in a T-maze to regain them. Although the injected septal cells could not have received afferents from normal sources innervating the septum, the cells apparently possess enough intrinsic information to restore function to a denervated hippocampus.

Interestingly, Olson has also demonstrated that adult adrenal chromaffin cells can substitute for substantia nigra in innervating intraocular striatum [13]. In animal models, the implanted chromaffin cells begin to secrete dopamine, instead of their usual product, adrenaline. Both of the European groups have used dopaminergic cells from fetal substantia nigra to alleviate the motor deficits in animal models of parkinsonism. Furthermore, Olson has extended his studies of adrenal medullary implants, and shown that they too will provide enough dopamine to prevent some of the extrapyramidal symptoms of parkinsonian rats. For application to human disease, the use of adrenal grafts would avoid the ethical and immunological problems of using cells from fetal donors.

Olson's group has proceeded stereotactically to graft adrenal tissue from two patients with severe medically intractable

Parkinson's disease into the head of the caudate of the brain[14]. The success has been marginal. One patient showed no improvement (and no additional impairment) and the other has had some minor reduction of symptoms in the arms alone. Olson speculates that the caudate might not have been the right location for the graft to prevent motor symptoms; recent studies on monkeys have suggested that the putamen is the striatal site more closely correlated with motor function[15].

Despite these initial clinical failures, information from animal studies of neural grafting is accumulating rapidly. As work on the pathophysiology of Parkinson's and other neurodegenerative disorders progresses, investigators will test their new animal models with intracerebral grafts. It is likely that within a decade or two, neurologists will have another therapeutic option for severely disabled patients, and a new neurology. □

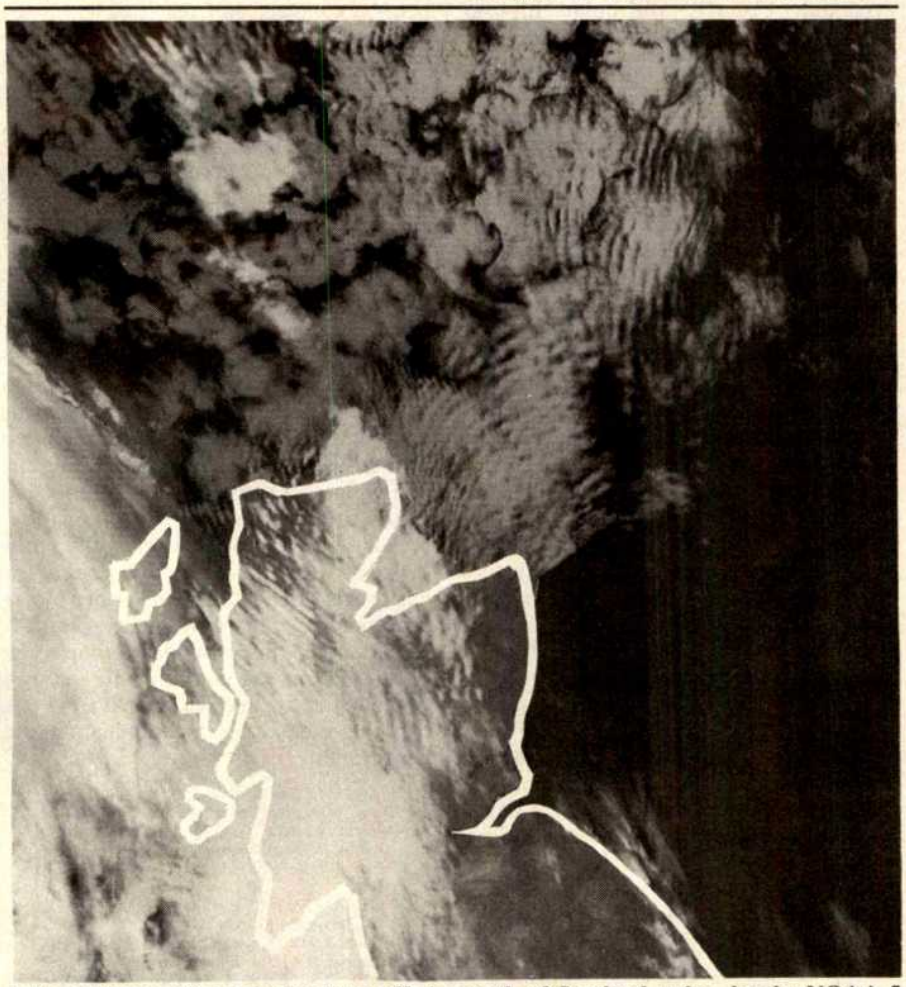
Cosmology

Coloured comets

from David W. Hughes

WHAT colour is a comet? There is no easy answer. Visually, they are rarely seen in true colour because the retinal cones, which respond to colour, are usually swamped by the rods when it comes to the nocturnal vision of faint objects. George F. Chambers, a prolific cometary observer at the turn of the century, found that comets 'exhibit a more or less silvery-grey hue'. There were some exceptions. The sensational assertions of our mediaeval ancestors that comets had the colour of blood, or were fiery red, were discounted by Chambers, although tinges such as yellow, yellowish and ruddy were thought possible, particularly for bright comets.



A quantitative approach to cometary colour can be made by measuring their brightness through a set of filters, as used recently by William Hartmann and Dale Cruickshank (*Icarus* **57**, 55; 1984). They analysed the V, J, H and K brightnesses of fourteen comets through filters centred on 0.55, 1.25, 1.58 and 2.2 μm. Defining an 'α index' as the position of a Solar System object on the J–H–K colour–colour diagram, Hartmann and Cruikshank find, crudely, that low (J–H), (H–K) brightness values (obtained by subtraction) are equivalent to high αs and vice versa. By looking at a range of asteroids, satellites and laboratory substances, the authors find that the α index increases both as a function of increasing albedo and as the ratio of ice to dirt area of the reflecting surface increases. The α index is also a function of colour, low values coming from dirtier redder surfaces, high values from bluer icier surfaces.

Data from the fourteen comets show clearly that cometary α indices increase as a function of heliocentric distance. Put simply, this means that as comets approach the Sun they become brighter and redden.

Unfortunately, the physical effects responsible for the α change are rather convoluted. First, changing the particle size distribution can change the colour, with the introduction of relatively more small particles causing reddening. Second, compositional changes can also affect the colour. Remote comets (such as Schwassman-Wachmann 1 at 6 AU) can release relatively stable icy-dust grains. When the comets are about 1 AU from the Sun, the ice component of the coma grain sublimates within less than an hour, so only the reddish carbonaceous dust remains to reflect sunlight. Notice that this mechanism could explain why the eruption of jets of fresh material from the nucleus can lead to sporadic colour changes — an injection of icier material turning the coma bluer. The third factor is phase. Asteroids certainly redden as they are observed at larger phase angles and comets could follow suit. Comets observed at similar phase angles do, however, exhibit significant differences in colour; the nature of the reflecting and scattering particles must therefore differ.

Hartmann and Cruikshank conclude that comets get redder as they approach the Sun and that this is not just due to a change of phase. The underlying cause is probably tied up with a decrease in the iciness of the dust being pushed away from the nucleus by momentum transfer from the sublimating gases. The closer a comet is to the Sun the hotter this dust becomes. Unfortunately we might have to wait for another brilliant daylight comet, the last of which was 1910 I, before we can see a blood-red comet with the naked eye. □

Infrared image of cloud structures off the north of Scotland, taken by the NOAA 5 satellite at 0335 GMT on 23 March 1982. The wave-like features are caused by buoyancy oscillations — 'gravity waves' — occurring in Arctic or polar maritime air masses. From a recent paper in *Meteorological Magazine* (113, 97; 1984) in which K.J. Weston relates oscillations in wind speed and direction measured at the surface, with periods of about 20 minutes, to such high-altitude phenomena. Photograph: University of Dundee.

X-ray crystallography

Advantages of electronic 'film'

from Stephen C. Harrison

BY comparison with other areas of molecular biology, the determination of macromolecular structure has suffered because of the time-consuming and tedious course of X-ray crystallographic investigations. Recent advances in genetic manipulation have made it possible to produce considerable quantities of all sorts of interesting proteins and protein–nucleic acid complexes, some of which have been crystallized. It is therefore of more than casual interest that as a result of progress in the technology of X-ray detectors we appear to be on the verge of achieving a substantial acceleration in the collection of intensity data from crystals. The new detectors are two-dimensional position-sensitive devices which permit the simultaneous recording of large numbers of reflections with the accuracy usually associated with one-reflection-at-a-time diffractometers.

The earliest X-ray intensity measurements from crystals were made by following ionization with a gold-leaf electrometer. The hands of Bragg *père* and Bragg *fils*, actuated by the beat of a metronome, served as the 'stepping motors' for moving the crystal through its reflecting position. (Bragg junior wrote an entertaining account[1] of the times in which the intensity of the 100 reflection from NaCl could be reported[2] to be '676, when the crystal was turned through five minutes of arc for each beat of the clock'). As more complicated structures came to be studied, recording with photographic emulsions became standard, since it enabled many reflections to be measured simultaneously. The advent of automated diffractometers in the late 1950s turned a large part of the crystallographic community to electronic data collection, using a proportional counter or similar device, but the inefficiency of recording only one reflection at a time made diffractometry a poor choice for larger or more complicated proteins. A simple calculation presented by Arndt[3] shows that for unit cells larger than about 150 Å, appropriate photographic recording is the significantly more efficient approach. Indeed, stepped oscillation or rotation photography has become standard in most laboratories working on large proteins and at synchrotron installations supporting macromolecular crystallography.

Photographic film is actually an excllent detector, and for 1.5 Å X rays it is about 70 per cent quantum efficient. Automated two-dimensional densitometers, such as the widely used rotating-drum scanners, make digitization of films and evaluation of intensities relatively straightforward, although in a number of cases the tedium of this step has proved rate-limiting. A more significant disadvantage of photographic measurement is the limitation to its accuracy imposed by the small fraction of recording time during which a given reflection is diffracting. In oscillation photography, a 1° photograph is 'typical', but the angular range over which a particular order diffracts might be 0.1–0.2°, depending on geometrical factors and crystal quality. Background is recorded on the film during the remaining 0.8–0.9°, decreasing the signal-to-noise ratio. This disadvantage could be eliminated by the expedient of recording a series of 0.1° photographs — and it is precisely this possibility, impractical with actual film, that is offered by the new devices.

Currently there are three quite different two-dimensional detectors for single-crystal X-ray diffraction, each based on different design ideas and on significantly different technologies. The device developed by U. Arndt at the Medical Research Council Molecular Biology Laboratory in Cambridge, and now marketed by Enraf Nonius, records the diffraction pattern on a fluorescent screen connected by fibre optics to an image intensifier[4,5]. The intensifier output is read by a television system linked to a computer. The Gd_2O_2S input screen is 47 × 63 mm and the final scan is binned at 512 × 512 pixels. The size of the screen and the point-to-point resolution imply that data to 3 Å resolution can be collected at a single detector setting from crystals with a 100 Å cell constant. Crystals with larger unit cells require a longer crystal–detector distance and several detector settings. The device includes a 4-circle goniostat to facilitate resetting.

The detector developed by N. Xuong and colleagues at the University of California at San Diego is a multiwire proportional counter, derived from detectors developed for high-energy physics[6,7]. It consists of a xenon-filled ionization chamber with delay-line readout from planes of parallel wires in x and y. It has an active area of 27 × 30 cm, with a spatial resolution of 0.6 mm full width at half maximum (FWHM) in the horizontal direction and 2 mm in the vertical direction. The modest resolution necessitates a large crystal–detector distance (1 m or more), and full recording of a protein diffraction pattern to 3 Å resolution may require multiple settings or an array of more than one detector. The set-up in Xuong's laboratory has already been used to solve several structures, including dihydrofolate reductase[8] and the large ('Klenow') fragment of *Escherichia coli* DNA polymerase I (T. Steitz, personal communication). A similar device has been constructed at the University of Virginia.

A different type of xenon-filled detector has been developed by R. Burns of the Xentronics Corporation, Cambridge, Massachusetts. It is also a multiwire device, but with capacitive readout and with much higher spatial resolution (0.2 mm FWHM in both x and y). Its active area is 12 cm in diameter, and it is fitted with a modified oscillation 'camera'. The high spatial resolution permits a single detector to mimic a conventional X-ray film. The Xentronics detector has been used to collect data from several quite challenging crystals, including tomato bushy stunt virus, with a unit cell constant of 383 Å, and in our preliminary experience has shown very favourable intensity statistics[9].

Each of these devices is likely to have its own niche in the ecology of crystallographic applications. An advantage of the television-based design is its inherently higher data-rate capacity. The xenon-filled devices are at present limited by dead time to a total rate (over the face of the detector) of 30–50 kHz. Although not a significant disadvantage with conventional sources, this limitation can restrict possible applications with synchrotron sources. The Xenotronics device has the advantage of being a compact unit that can be moved easily from one X-ray set to another. Its large active area and high spatial resolution also give it an edge in the large-unit-cell range.

The gain in signal-to-noise that detectors offer with respect to film can be used either for increased accuracy or for increased speed. The increased accuracy will be especially helpful for medium-to-large unit cells, where reliable heavy-atom differences have sometimes been difficult to measure and noisy difference data difficult to interpret. The increased speed offered by these new approaches to data collection is likely to have immediate impact in the analysis of variants, mutants, modified proteins, active-site complexes and the like. Since these aspects of an investigation follow the initial structure determination, they are usually not held up by the phase problem (for example, the search for heavy-atom derivatives) but rather by the process of intensity measurement itself. It should soon be much simpler to couple site-specific mutagenesis and X-ray crystallography, in order effectively to test hypotheses based on the examination of a new structure. □

Linear scale for acid rain?

SIR — "Acid rain" is a scientific issue for which careful presentation of results is of considerable importance, especially as the issue has entered the domain public debate in the United Kingdom. It is therefore right to ask whether we always present the results of acidity measurements of rainfall and freshwaters in the most appropriate way. The answer, I believe, may be no.

The acidity of rainfall and freshwater bodies is commonly reported in terms of the *p*H. This is a long established scale and one that is particularly convenient for expressing concentrations of hydrogen (H^+) ions (strictly speaking H^+ activity) when they range over several orders of magnitude. Difficulties in its use can arise from a failure to recognize that, being logarithmic, the *p*H scale is not linear. Confusion on this count, particularly in nonscientific circles is easy to imagine. Even in scientific circles a drop in *p*H of say 0.5 units appears at times to be treated as being equivalent, whether it occurs from *p*H 6.0 or from *p*H 5.0. In fact, the former case represents an increase in the H^+ ion concentration of some 2 microequivalents per litre, the latter of around 22 microequivalents per litre.

To give a more specific example, definition of trends over time in acidity levels has been commanding a great deal of attention. This is of some importance in establishing the relationship between emissions of sulphur dioxide and nitrogen oxides and subsequent acidification of the environment. Unfortunately, records of *p*H measurements of both rainfall and natural water bodies go back only several decades and even then there are problems over the continuity and quality of the data. Diatom stratigraphy in lake cores appears to provide one means of overcoming these problems, as demonstrated in the recent paper by Flower and Battarbee[1]. By measuring the changes in the diatom population in a ^{210}Pb dated sediment core they were able to reconstruct the *p*H history of a lake in the south-west of Scotland over the last 400 years or so (Fig. 1*a*).

It is at this point, however, that caution needs to be exercised. Interpreting trends on the basis of the data as presented in Fig. 1*a* is not straightforward, due to the use of *p*H on the abcissa. Expressing the results in terms of H^+ ion concentration on a linear scale gives a significantly different impression of the trend over time in this lake (Fig. 1*b*).

To emphasize this point, the results in Fig 1*a* indicate that about half the total change in *p*H had taken place by around 1900. Furthermore, almost all of the change had taken place by 1930 with very little change after 1940. In other words the major *p*H change took place early in the first half of the present century. But in terms of H^+ ion concentration, half of the change had taken place by the later date of around 1920, while there was a further steep increase from around 1950 to the present (Fig. 1*b*).

The use of a linear representation of concentrations provides the most appropriate means of representing the magnitude of any changes in concentration. (This is not to say though that effects are necessarily related linearly to concentration.) It is therefore encouraging to see a move to the use of a linear scale in reporting rainfall chemistry data in the United Kingdom[2]. Indeed a widespread adoption of the linear concentration scale when reporting H^+ ion concentrations, especially in acidic rainfall and freshwaters, would appear to be overdue.

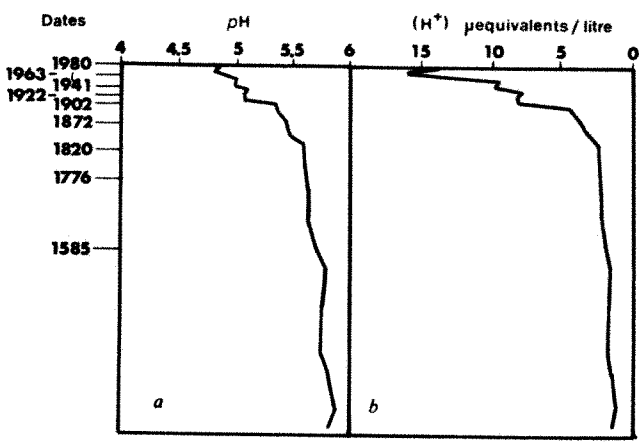

Fig. 1 Reconstruction of H^+ ion concentration history in Round Loch of Glenhead. *a*, Using *p*H scale (logarithmic); *b*, using linear concentration scale. (Based on ref. 1.)

Alphabet and the Western mind

SIR — The unprecedented genius of Greece is unexplained. I conjecture that the modern study of the mind provides some tentative answers.

Before the Golden Age of Greece, the Greeks had developed their alphabet. This writing system is unique in possessing, by symbolizing vowels as well as consonants, a fully phonetic representation of language. This is achieved at the cost of limiting the representation of writing in the brain, as only the left cerebral hemisphere contains areas which are competent in the required phonetic analysis[1]. This has led to the ubiquity of the association, in the alphabet-dominated modern world, between injuries to the left hemisphere and impairments of writing and reading skills. This, however, is not a necessary restriction with all writing systems. Non-phonetic writing systems can use reading strategies involving the right hemisphere. Indeed, neurological studies show that hemispheric representation of non-alphabetic writing systems differs markedly from that encountered with alphabetic ones. Hatta[2,3] and others[4,5] have shown that logographic characters are more efficiently recognized by the right hemisphere. Sasanuma[6] has shown that *Kanji*, the non-phonetic writing system of Japanese, is vulnerable to different areas of brain injury from *Kana*, the phonetic system of Japanese writing.

There is evidence that reading retardation is associated with reduced involvement of the left hemisphere in reading[7]. In its absence such readers rely on the right hemisphere, which has been shown to have the ability to read simple English words independently of the left hemisphere[8]. In the absence of left-mediated phonetic analysis, the reading of frequent lexicals can occur through a non-phonetic strategy of logographically recognizing them from their shapes. It has been shown that retarded readers can learn to read Chinese logograms with their English translations more proficiently than their alphabetic equivalents[9]. Present studies of right hemispheric reading competence uses alphabetic lexicals which require left hemispheric phonetic decoding skills that disadvantage it rather than logographic ones which do not. I therefore suggest that the reading ability of right hemispheres for these and other non-Western writing systems will be found to have been underestimated. The right hemisphere, I conjecture, is fully competent, probably more so than the left hemisphere, to read, at the level of understanding which ancient societies used them, hieroglyphics, logograms and other non-alphabetic writing systems.

There are independent reasons for believing that pre-alphabetic writing systems were represented in the right hemi-

sphere. Such systems adopt a sinistral, that is, right to left, direction of writing and reading scan. Studies of eye scan direction have shown that sinistral scan direction favours a perception of lexicals to the left of the visual fixation point[9]. Such displacement of lexical perception into the left visual field would be expected if lexicals were preferably processed in the right hemisphere. Likewise as dextral scanning produces a perception of lexicals to the right of the fixation point, the dextrality of the Greek alphabet would follow from the adoption of a left hemispheric perception of lexicals through the right visual field.

Why should the development of a left rather than a right or bilateral representation of writing, as a consequence of the alphabet, have led to the Greek intellectual revolution? The answer probably lies in the fact that "competences" within the brain compete for expression. Analogously to Mendelian genes, the competences of the mind can have a dominant or recessive relationship to each other. Levy and Trevarthen[9] have shown that when two hemispheres each possess a competence able to answer a question, only one will do so. Though often the dominant competence will be superior in correctly replying compared with the recessive competence it dominates, frequently the recessive competence, as found by unilaterally testing it, will have a superior ability to answer to the question correctly than the competence which dominates it.

I conjecture that the alphabet, by producing a unilateral representation of lexicals in the left hemisphere, freed recessive competences in the left hemisphere which underlie rational, analytical and logical thought. These competences were previously overshadowed, inhibited and restricted in their development by a right hemispheric set of competences deriving from its representation for lexicals.

Alignment of base sequences

SIR — In a recent paper Richards *et al.* show[1], in their Fig. 4, an alignment in which they claim that gaps "were inserted to maximize the number of base matches". The authors are to be commended on the clarity of phrase "number of base matches" when so many would have preferred the ambiguous term "homology". They have, nevertheless, still managed to mislead the careless reader as the following segment of their alignment shows:

```
------CCTTCAGAATACAGAATAGGGACATAGAGA
ATCCCACCCAGCCCCCTGGACCTGTAT---------
```

(Underlining shows the base matches.) An alternative alignment might be as follows:

```
CCTTCAGAATACAGAATAGGGACATAGAGA
ATCCCA---CCCAGCCCCCTGGACCTGTAT
```

This alignment reduces the number of gaps in this region by 50 per cent, reduces the number of gapped residues by 80 per cent, and increases the number of base matches by 133 per cent. More modest improvement around two of their other gaps is also possible. If I can increase the number of base matches by removing gaps, then clearly the authors' insertion of gaps did not maximize that number. One should seldom claim that one has maximized anything in the absence of a rigorous algorithm to accomplish that task[2]. It is sufficient (and frequently correct) to assert that gaps have been introduced to increase the number of base matches.

Fissure animals of Bristol and South Wales

SIR — Michael Benton has given a fair account of the published material on the Upper Triassic and Lower Jurassic fissures of Bristol and South Wales[1]. However, in reviewing my work on the fissures, he missed some important aspects.

He states that "we must now view the fissure animals as representing a sample of a lowland fauna rather than a peculiar upland fauna". In particular, the tetrapods should be viewed as representing an *insular* lowland fauna and not the usual continental lowland fauna. The poorly dated mammal-bearing fissures of South Wales are generally described as being on islands[2,3] of (probably) Lower Liassic Age, whereas the specifically dated[4] Tytherington fissure fauna can be viewed as being derived from a small low-lying Rhaetian island habitat[5]. Indeed, the incidence of these tetrapod faunas, which are dominated by species with a small body size, is remarkably similar to Quaternary herpetofaunas found in solution fissures[6] or banana-holes[7] of modern-day islands.

The importance of this concept, that the Bristol and South Wales fissure animals are derived from insular Triassic/Liassic faunas, cannot be underestimated. Because of the small land areas on which they live each reptile species would have had a relatively low overall population size and thus would be subject to rapid rates of genetic drift and a high probability of extinction. Insular faunas are impoverished and show evidence of disharmony[8]. Therefore the biota could be expected to be unusual in respect to other preserved faunas of the same age, and any given fissure reptile species may show aberrant features compared to its contemporaneous unpreserved relatives. In this respect, rather than being closely related to *Anchisaurus* as generally proposed[9], *Thecodontosaurus* is more likely to be a dwarf plateosaurid (either *Plateosaurus* or *Lufengosaurus*). Full details are in preparation but, for example, it is the case that the basioccipital and basisphenoid of *Thecodontosaurus antiquus* discovered at Durdham Down is much more similar to that of *Plateosaurus* than that of *Anchisaurus*.

The high turnover rates expected on these small limestone islands lying near the Welsh and European landmass would also provide one alternative interpretation of the differences between the limestone faunas of the Slickstones fissures described by Fraser and Walkden[10].'

The remarkable preservation of the many tiny reptile bones can easily be explained by the short transport distances from death to burial expected in small islands. Indeed, deposition of the bones may be at least partly below sea level (see ref. 5).

Finally, reptile remains were described from Durdham Down fissure[11], and lepidosaur vertebrae were found in Holwell[12]; both these reports predate the description of *Clevosaurus* in 1939, that Benton refers to as the earliest description of reptile remains from these fissure deposits.

Stoichiometry and the structure and stability of inorganic solids

M. O'Keeffe

Department of Chemistry, Arizona State University, Tempe, Arizona 85287, USA

B. G. Hyde

Research School of Chemistry, The Australian National University, PO Box 4, Canberra, ACT 2601, Australia

Stoichiometry (cation/anion ratio) is an important factor in determining the structure and stability of many inorganic crystals. It directly affects the coordination numbers of atoms, the relative stability of oxidation states and the tendency to form compounds with bonds between like atoms. Cation-rich binary compounds, especially oxides and nitrides, are either relatively unstable (have reduced bond energies) or do not exist. In such cases peroxides and azides are preferentially formed; these have normal bond energies.

WE are concerned here, in a very general way, with the role of stoichiometry in determining the structure and stability of simple inorganic solids. Although elementary, its importance in chemistry has generally been underestimated (but see ref. 1). We find that several observations, otherwise not readily explicable, are susceptible to a simple rationalization in terms of the constraints imposed by stoichiometry (which are ultimately those of valence). The emphasisis is mainly, but not exclusively, on binary compounds of main group metals with nitrogen, oxygen and fluorine.

We first distinguish between normal compounds and polycompounds. The former are those in which there are bonds only between unlike atoms (as in SiO_2). In the latter[2] there are also identifiable bonds between like atoms (as in azides and peroxides). These terms provide at best a rough classification; in general there is no rigorous criterion for deciding whether any two atoms in a molecule or a crystal are, or are not, bonded together. It is well known[3,4], for example, that bond-order criteria based on interatomic distances (d) often lead to results contrary to intuition. (For example, in Mg metal, d(Mg–Mg) = 3.21 Å, whereas in MgO, d(Mg–Mg) = 2.98 Å.) Equally, it is now recognized[5] that the presence of a build-up of electron density between atoms does not automatically indicate the presence of covalent bonding.

In the normal compounds of the main-group elements, the oxidation states are mainly determined by the position of the element in the Periodic Table. Accordingly, there is usually just one normal binary composition for a given pair of elements (such as, Cs_2O), although the compound may well be polymorphic. (There are obvious exceptions involving mainly pairs of the more-electronegative elements such as the sulphur or nitrogen oxides.) On the other hand, the same pair of elements may well form a number of polycompounds such as Cs_3O, Cs_2O_3, $Cs_{11}O_3$ and Cs_7O. Note that Cs_2O_3 [$= Cs_4(O_2)_3$] has both polycations and polyanions.

Pairs of elements which form stable normal compounds, very often do not form polycompounds [for example, AlN but not $Al(N_3)_3$] and conversely, those which form stable polycompounds often do not form stable normal compounds (for example, NaN_3 but not Na_3N). In what follows we generally discuss stability with reference to dissociation to free atoms (bond energies); although by this test Na_3N may well be stable, however, we shall argue that in this instance the bond energy is unusually low.

Our approach is largely phenomenological. In particular we will not discuss whether compounds are 'ionic' or 'covalent', although for convenience we shall use the terms *anion* and *cation* when the context leaves no room for ambiguity. We shall, however, offer an interpretation of our observations on the properties of metal-rich compounds (those with cation/anion stoichiometric ratios significantly greater than one) in which we identify a destabilizing influence of cation–cation interactions. Here a 'size' effect clearly emerges.

Bond energies and strengths

The term bond strength is used as defined by Zachariasen[6], so that for bond strengths v_{ij} between atom i and neighbours j

$$\sum_j v_{ij} = z_i \qquad (1)$$

where z_i is the valence of i. For a symmetrical coordination polyhedron v is the Pauling[7] electrostatic valence. In the absence of large interactions between next-nearest neighbours, v_{ij} is, to a good approximation, a unique function of the bond length r_{ij}.

Elsewhere[8] we have used the concept of equivalent bond enthalpy (the bond dissociation energy per unit bond strength) and demonstrated that (with exceptions of special interest below) it is approximately constant for bonds to a given metal in oxides. The enormous number of natural chemical compounds shows that equivalent bond enthalpies must be approximately constant for any pair of elements.

In rare instances, for example CO_2, high order ($v > 1$) bonds are favoured. More commonly, the situation is one in which structures with many weaker bonds are favoured to an alternative with fewer strong bonds: an example is SiO_2. Thus, in general, large coordination numbers are preferred, and this gives rise, for most combinations of elements, to solid structures. Fragmentation of structures into molecules, with low coordination numbers, is the exception, and occurs only with relatively few combinations of elements. We are mainly concerned, therefore, with the factors that provide upper limits to coordination numbers.

Coordination numbers in crystals

In most crystals, coordination numbers are determined by three principal factors. The first two involve a balance between the tendency to form as many bonds as possible, and the interactions (normally, but not necessarily, repulsions) between the next near-nearest-neighbour atoms. Note that when considering such interactions, the 'size' of an atom is its non-bonded size[9], which has no relationship to conventional ionic radii. Indeed, the failure of the ionic radius ratio rules for coordination numbers has long been recognized[10], but still not generally accepted. This neglect has led to the erroneous point of view that (to take a specific example) cation coordination numbers in oxides are

solely determined by oxygen–oxygen repulsions and not by cation–cation repulsions.

An important point is that cation and anion coordination numbers are not independent: by definition, each bond has a cation at one end and an anion at the other, so that the ratio of the average coordination number of the anions to that of the cations is equal to the stoichiometric cation/anion ratio[11]. Thus is SiO_2, ^{iv}Si implies—at least on average—^{ii}O, and we may ask whether the coordination number of Si in SiO_2 is limited to four (at ordinary pressure) because no more than four oxygen atoms can fit around a silicon atom, or because no more than two silicon atoms can fit around an oxygen atom. We prefer the second point of view[9].

In order that the shortest interatomic distances in normal crystals be between cations and anions, coordination numbers must clearly be less than, or equal to, 12. In binary compounds the limiting value is only reached in exceptional structures such as those of Cr_3Si and WAl_{12} (hardly normal compounds in the present context). In practice this third constraint limits coordination numbers in normal compounds of nitrogen, oxygen and fluorine so that values in excess of nine are very rare. It follows that when the cation/anion ratio is very different from unity, the majority component will have a rather low coordination number (thus four for Rb in Rb_2O and two and three for Li in Li_3N). This important influence of stoichiometry in influencing coordination numbers appears largely to have gone unrecognized although N. V. Belov (quoted by Lebedev[10]) apparently realized, but did not explain, the phenomenon.

Examples of unusual coordination numbers are to be found among the many cation-rich ternary oxide structures determined by Hoppe and coworkers[12]. Thus transition metal cations in planar 3-fold coordination are found in Na_4MO_3 (M = Zn, Fe, Co and Ni) and in $Na_{10}Co_4O_9$, and Ni(II) is in linear 2-fold coordination in K_2NiO_2. We emphasize that these low coordination numbers for the cations are due in large part to the high stoichiometric ratio of cations to anions in the compounds.

We have mentioned that in SiO_2, the coordination number of Si was largely determined by the difficulty of fittihg three Si atoms around an oxygen atom. This is neatly illustrated by the structure of SiP_2O_7 in which the increased anion/cation ratio allows silicon to be six coordinated by oxygen while keeping the oxygen coordination at two (that is $^{vi}Si^{iv}P_2{}^{ii}O_7$). There are several other silicon phosphates in which the coordination number of silicon is similarly controlled by stoichiometry[13].

Irregular coordination figures

The occurrence of irregular coordination figures in structures can also be a simple and inevitable consequence of stoichiometry. We illustrate this point by stoichiometry M_2X_3. If M is to have coordination number four, X atoms must exist in at least two different coordinations (the average coordination number of X being 8/3). Thus $^{iv}B_2{}^{ii}O^{iii}O_2$ for the structure of high-pressure B_2O_3. In this compound the sum rule, equation (1), requires that the strengths of the bonds to the two-coordinated oxygen are $v = 1$ and for the three-coordinated oxygen, $v = 2/3$. As bond strengths and bond lengths are strongly correlated[14] these two bond strengths correspond to different bond lengths—in this example 1.38 Å and 1.51 Å respectively. The coordination figure about boron ($B^{ii}O^{iii}O_3$) is correspondingly an irregular tetrahedron. The irregular coordination figure about La in A-type La_2O_3 (in which La is in 7-fold coordination) is similarly explained.

In such structures, the Pauling[7] electrostatic valence sum rule is not obeyed, and according to Pauling's hypothesis they are destabilized. Certainly there are no stable oxides of stoichiometry M_2O_3 in which all the M atoms are in four-coordination despite the fact that atoms such as B, Al, Ga, Fe(III) are frequently in four coordination in ternary oxides and such like. We caution against too much generalization; for some metals (notably the early transition elements) distorted coordination polyhedra are in fact more stable than regular ones (as illustrated by the structures of MoO_3 and WO_3). Nevertheless,

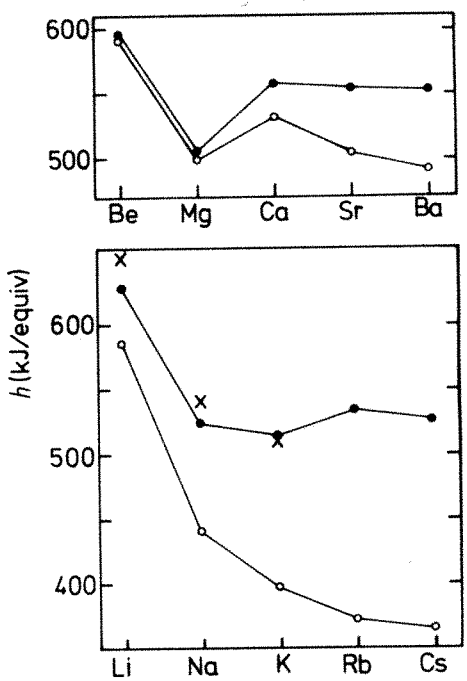

Fig. 1 The equivalent bond enthalpy, h, in alkali and alkaline earth oxides. ●, Ternary and similar oxides[8]; ○, normal binary oxides; ×, peroxides.

the instability of irregular coordination figures of the type just discussed is the reason for some departures from the general rule that cation coordination decreases with increasing cation/anion ratio. An obvious example is $^{iv}AlPO_4$ and $^{vi}Al_2O_3$; another is the structure[15] of Na_3NO_4 with ^{iv}N (nitrogen is considered a cation in this context) in contrast to ^{iii}N in $NaNO_3$.

Bond energies

An earlier study[8] of heats of atomization of oxides showed that there is a constant contribution, per unit of bond strength, for each M–O bond, to the total heat of atomization of ternary and similar oxides. With the exception of the alkali metals and, to a lesser extent, the heavier alkaline earth metals, the contribution from each element was equal to the equivalent heat of atomization of its binary oxide.

The data of that study (for Li, Na and K) have now been augmented with the few available data for ternary oxides of Rb and Cs (ref. 16). These have been used to calculate the equivalent bond enthalpies both in binary and in ternary and such like oxides that are shown in Fig. 1. Note that these quantities differ by an amount that increases with increasing size (atomic number) of the metal atom. The most obvious way that the binary oxides differ from the rest is in stoichiometry; the latter all had cation/anion ratios less than one, in the former it is two. We suggest that the higher proportion of metal atoms in the binary oxides result in significant cation–cation interactions which destabilize the crystal to an extent that increases with cation size. This view is strongly supported by the observation[17] that bond lengths in alkali metal oxides are anomalously lengthened (compared with those in ternary compounds) in a parallel manner.

Figure 1 also shows the M–O equivalent bond enthalpies in the peroxides M_2O_2. These were calculated from the heats of atomization of the solid peroxides by subtracting the O–O bond energy, the latter coming in turn from the heats of atomization of H_2O and H_2O_2 (ref. 18). It may be seen that they are normal in the sense that they lie very close to the points found for the ternary oxides, showing clearly that the increasing tendency to peroxide formation with increasing atomic number is due, not to enhanced stability of the peroxide, but rather to decreased stability of the normal binary oxides.

For the nitrides and azides fewer relevant data are available. However, Wattenberg's[19] work shows that if it exists at all, Na_3N

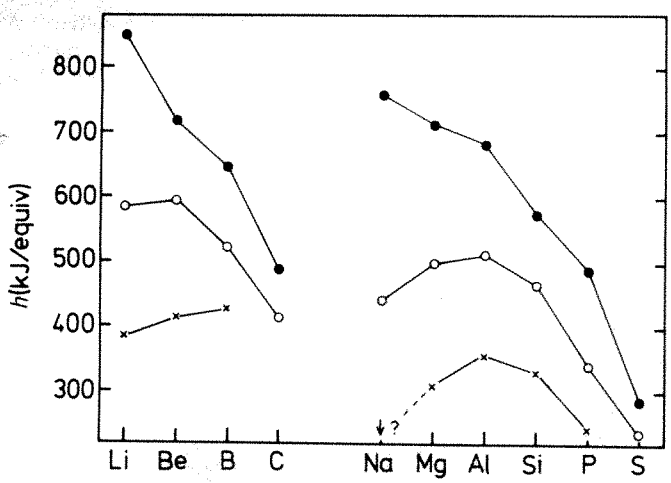

Fig. 2 Equivalent bond enthalpies (heats of atomization per equivalent) for binary solids. ●, Fluorides; ○, oxides; ×, nitrides. The arrow represents the upper limit for Na_3N derived in the text.

is metastable with respect to Na(metal) and N_2. Thus for the reaction $6Na + N_2 = 2Na_3N$, $\Delta G^0_{273} > 0$ from which we estimate $\Delta H^0_{273} > -57$ kJ mol^{-1}, and hence an upper limit for the equivalent bond enthalpy in the binary compound h_0(Na–N) < 260 kJ mol^{-1}. A value for the equivalent bond enthalpy h(Na–N) in NaN_3 may be obtained in the same manner as for the peroxides (that is using data for NaN_3, HN_3 and NH_3) giving h = 554 kJ mol^{-1}. Although rough estimates, the difference $h - h_0$ is striking and demonstrates that sodium nitride, like sodium oxide, has an anomalously low bond energy.

Figure 2 shows equivalent bond energies for normal binary compounds with N, O and F. The fluorides show the expected trend of bond energy increasing with increasing electronegativity difference. However, bond energies to N, and to a lesser extent, to O are clearly anomalous in the case of Na and, to a lesser extent Mg. (In contrast, the equivalent bond energies in ternary, and similar oxides[8] show the expected trend similar to that of the fluorides in Fig. 2).

Nonexistent compounds

We have called attention to the reduced stability (and consequent lengthened bonds) in certain metal-rich normal compounds. The effect was larger for heavier metal atoms and larger metal/non-metal ratio. It might then be expected that certain compositions are not realized as stable phases. This indeed occurs. It is also found that when the normal compounds do not exist, stable polycompounds are the rule. We are particularly concerned with providing a simple rationalization for the non-existence of normal binary compounds which might be expected to be stable on the basis of a large difference of electronegativity between the two components.

It is at first sight surprising that so few normal carbides of the main group elements are known. These seem to be restricted to SiC, Al_4C_3, Be_2C and, possibly[20], Li_4C. The other alkali metals readily form graphite intercalation compounds (a form of polycompound) and acetylides but not solid M_4C. The heavier alkaline earth metals form only acetylides. It seems clear that these observations may be simply and directly explained as a consequence of the large number of metal–metal interactions that would be imposed by the stoichiometry of the missing compounds. The non-existence of other compounds such as GeC may be ascribed to the same cause. Here we are noncommital about the nature of metal–metal 'interactions'; molecular orbital calculations[21] on molecules such as Li_4C and Li_3N show signs of a bonding overlap population between the lithium atoms and indeed hypervalent molecules such as Li_6C are also predicted[22] to be stable (and here there are clear indications of Li–Li bonding).

In contrast to the carbides, all the alkaline earth metals form normal silicides (increasing bond lengths act to mitigate metal–metal interactions). Silicon and aluminium do not react, but the difference in electronegativity is becoming rather small.

We have already remarked on the relative instability of Mg_3N_2 and by inference of the other alkaline earth nitrides, and of Li_3N. It is clear[18] that the other alkali metals do not form normal nitrides, but they all form stable azides. The size effect is also apparent here in that the rest of the normal alkali metal pnictides are well characterized[1].

The complementary instability of at least some polycompounds can again be ascribed to the constraints of stoichiometry[2]; $Al(N_3)_3$ for example, would be very crowded indeed—but now with anions rather than cations. The problem of the stability of peroxides and azides is closely analogous to that of the stability of oxysalts—for example, the only stable anhydrous perchlorate are those of the alkali metals and the alkaline earths other than beryllium[23]. Wells[1] has discussed the stability of such salts from a similar point of view to ours.

Oxidation states

We have presented quantitative evidence that cation-rich oxides have abnormally low stabilities. In the case of ternary transition metal oxides, it is clear that the cation/anion ratio could be decreased (and the stability increased) by increasing the oxidation state of the cation. Alternatively, a high oxidation state of a transition metal could be stabilized by forming a ternary oxide with a low valence metal, and, indeed, high oxidation states of transition metals are readily obtained in ternary alkali–metal oxides. Thus although the highest stable oxidation states in the binary oxides are Mn(IV) and Ni(II), $KMnO_4$ [with Mn(VII)] and Na_5NiO_4 (ref. 24) [with Ni(III)] are known.

Conversely, higher oxidation states are destabilized by a large anion/cation ratio. Despite the (frequently correct) assertion that fluorine tends to develop the highest valence of a cation [thus Ni(IV) in ternary fluorides[24]], this is not the case for transition metal cations having the potential of high valence. For example, CrO_3 is known but not CrF_6 (ref. 25). The oxidizing power of fluorine is allowed full rein when combined in ternary fluorides with alkali and alkaline earth metals (especially the heavier ones). Then we find, for example, Cs_2MF_6 with M = Cu(IV) or Ag(IV) [contrast M(II) as the highest oxidation state in the binaries] and $CsAuF_6$ with Au(V) (ref. 24).

Conclusions

We have shown how the constraints of stoichiometry affect both the structure and stability of simple inorganic solids. Although simple and obvious, our ideas provide a unifying understanding of a range of phenomena that have not previously been explained, except perhaps in isolated instances on an *ad hoc* basis. We have adduced only a few more-striking examples to illlustrate our thesis. But we have not omitted any counter-examples known to us.

There have, of course, been numerous previous attempts at developing useful generalizations concerning the relative stability of inorganic solids. One of the first and most successful was that of Ramberg[26], who compared the relative stabilities of pairs of salts, and deduced that the low-energy assemblages were those in which the most highly charged cations were combined with the most highly charged anions (that is, $Mg_3N_2 + LiCl$ rather than $Li_3N + MgCl_2$)—the interpretation of such rules in terms of the ideas we have set out here should be clear.

It should also be clear that we provide a rationalization for the observation that the heats of reaction between acidic oxides and basic oxides is large, for example,

$$Na_2O + SO_3 = Na_2SO_4 \qquad \Delta H^\circ = -579 \text{ kJ mol}^{-1}$$

whereas that between amphoteric oxides is small, for example,

$$MgO + Al_2O_3 = MgAl_2O_4 \qquad \Delta H^\circ = -25 \text{ kJ mol}^{-1}$$

However, note that many of the observations that we have made are not in accord with the generalizations of the theory of hard

and soft acids and bases (HSAB)[27] which has several features in common with Ramberg's treatment. Thus according to the HSAB approach, hard acids such as Na should form more stable compounds with hard bases such as N than with weak bases such as As. Our discussion shows that the converse is true. Another prediction[28] of the HSAB theory is that to stabilize an element in a high oxidation state it should be surrounded by hard bases such as O^{2-}. We have seen that in solid compounds, the addition of hard acids such as Na^{+} is, in fact, what is required.

Optical counterparts of unidentified IRAS point sources: infrared luminous galaxies

Marc Aaronson

Steward Observatory, University of Arizona, Tucson, Arizona 85721, USA

Edward W. Olszewski

Dominion Astrophysical Observatory, Herzberg Institute of Astrophysics, 5071 West Saanich Road, Victoria, British Columbia, Canada V8X 4M6

Deep charge-coupled device imaging has been used to identify a number of IRAS (Infrared Astronomical Satellite) blank field sources with distant galaxies, and indicates that most high-latitude unidentified IRAS point sources have an extragalactic origin. The present sample of galaxies seems to include some with the largest known ratios of IR-to-optical luminosity, with values of L(IR)/L(B) *ranging upwards of 200. A redshift obtained for one source, 0422+009, indicates that this object has ~35 times the absolute IR luminosity of the starburst galaxy M82.*

HOUCK *ET AL.*[1] have recently reported several point-like 60-μm sources with no obvious visible counterparts. Possible explanations for the nature of these sources include high redshift galaxies, heavily obscured young stars, evolved stars with circumstellar dust shells, nearby 'Jupiter-like' bodies, or some fundamentally new type of object. To help establish which of the possibilities is correct, we have obtained deep, near-red images centred on the Houck *et al.* source positions.

CCD imaging

Houck *et al.*[1] present nine unidentified sources: six near RA 4 h, and three near RA 17 h. On the night of 9–10 December 1983, the prime focus charge-coupled device (CCD) camera of the 4-m telescope at Cerro Tololo was used to observe five of the RA 4 h fields. Four-minute *I* band exposures were obtained for each field, and for three of the sources, 5-min *R* band exposures were also secured.

Images of the observed fields are presented in Fig. 1. Following standard procedures[2], the CCD data have been trimmed, debiased, flattened to ~0.3% across the frame by exposures on both dome and smoothed blank sky, and corrected for fringes arising from night sky emission. Low-level (~1%) fringing remains in the data. Also shown in Fig. 1 are the IRAS error ellipses from Houck *et al.*[1], together with several galaxies that we have found lying within or near the ellipses. An examination of the radial brightness profile easily distinguishes non-stellar from stellar objects in our data. We first discuss each of the six RA 4 h sources.

0358+223. No CCD data were obtained for this field. However, a bright, stellar-like object is visible on the Palomar Observatory Sky Survey (POSS) at the virtual centre of the IRAS error ellipse[1]. Careful examination of POSS plates stored at Kitt Peak shows that the image of this object is 'soft', indicative of a distant galaxy which we identify with the IR source. The POSS prints examined by Houck *et al.*[1] are presumably inadequate for such fine discrimination.

0404+101. Figure 1 shows a faint galaxy near the centre of the IRAS error ellipse which we identify as the IR source. This object is visible just at the red plate limit of the POSS.

0412+085. We do not identify this source with any obvious optical counterpart. A faint galaxy does fall on the edge of the error ellipse, but we are hesitant to claim correspondence with it. First, because the IR-to-optical luminosity ratio would be uncomfortably large, even in comparison with the other great values derived later here; and more important, the probability of chance superposition for galaxies this faint becomes significant[3]. Further, re-examination of the IRAS data indicates that the source is probably extended, and therefore likely to be a hotspot on the IR cirrus (C. A. Beichmann, personal communication) present in this region (see ref. 4). The source has, in fact, the lowest signal-to-noise ratio of those reported by Houck *et al.*[1]. If it eventually does prove point-like, correspondence with

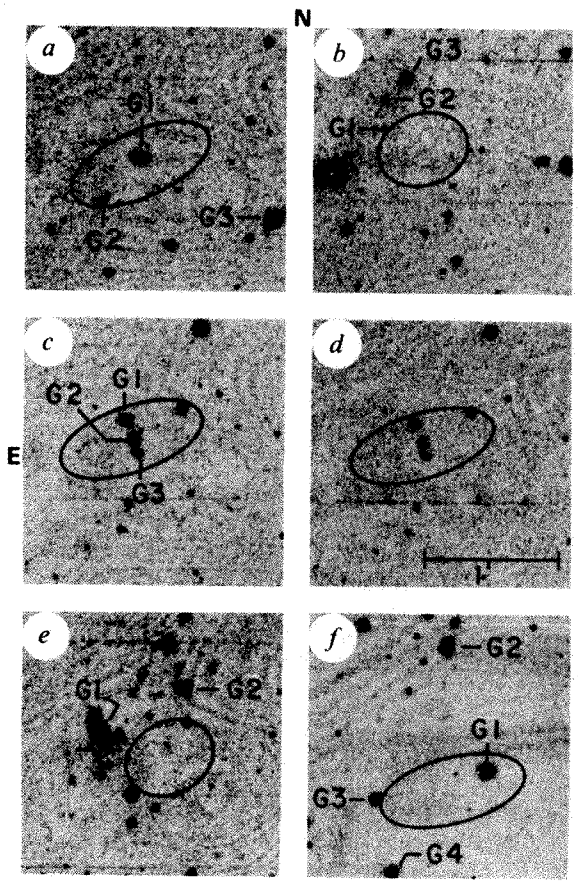

Fig. 1 CCD images of: *a*, 0404+101 (*R* band); *b*, 0412+085 (*I* band); *c*, 0413+122 (*R* band); *d*, 0413+122 (*I* band); *e*, 0422+009 (*R* band); and *f*, 0425−012 (*I* band). IRAS error ellipses from Houck *et al.*[1] are also shown. The alternative IRAS position for 0422+009 is marked in *e*. Galaxies are numbered as in Table 1. The orientation and scale for all images is identical.

galaxy number 3 may remain a possibility, although this object does fall a long way out of the present error ellipse.

0413+122. A galaxy triplet is located in the IRAS error ellipse. We suspect that galaxy number 2, near the centre of the ellipse, is the IR source. This object looks obviously disturbed, and the slightly distorted shape of galaxy number 3 is suggestive of tidal interaction between the two. The asymmetrical appearance of galaxy number 2 may be partially due to what looks like either a dust lane running along the north-east side of the object, or to two galaxies being viewed in close superposition. The triplet is again just visible at the POSS red-plate limit.

0422+009. Figure 1*e* shows that no obvious counterpart is present in the original IRAS error ellipse. However, an alternative source position obtained from later scans of the area (C. A. Beichmann, personal communication) places the IR source nearly coincident with a galaxy that appears to be the brightest member of a small cluster. Given the odd morphology and rather 'dusty' appearance of this object, we conclude that it is in fact the IR source (although there appears to be no *a priori* reason for preferring either of the two source positions marked in Fig. 1*e*).

0425−012. The radial profile of the stellar-like object in the error ellipse (see also ref. 1) establishes it as a galaxy, which we identify with the IR source. The image on the POSS red plate is also soft, although less obviously so than for 0358+223. (We have also examined the POSS plates at the positions of the three RA 17h sources listed by Houck *et al.*[1], and find that galaxies appear to be present in at least two of the error boxes.)

We now need to assess the probability of chance background contamination. For this purpose we use the r_F counts of Shanks *et al.*[3]; over the colour range of interest, $r_F \approx R$ magnitudes on

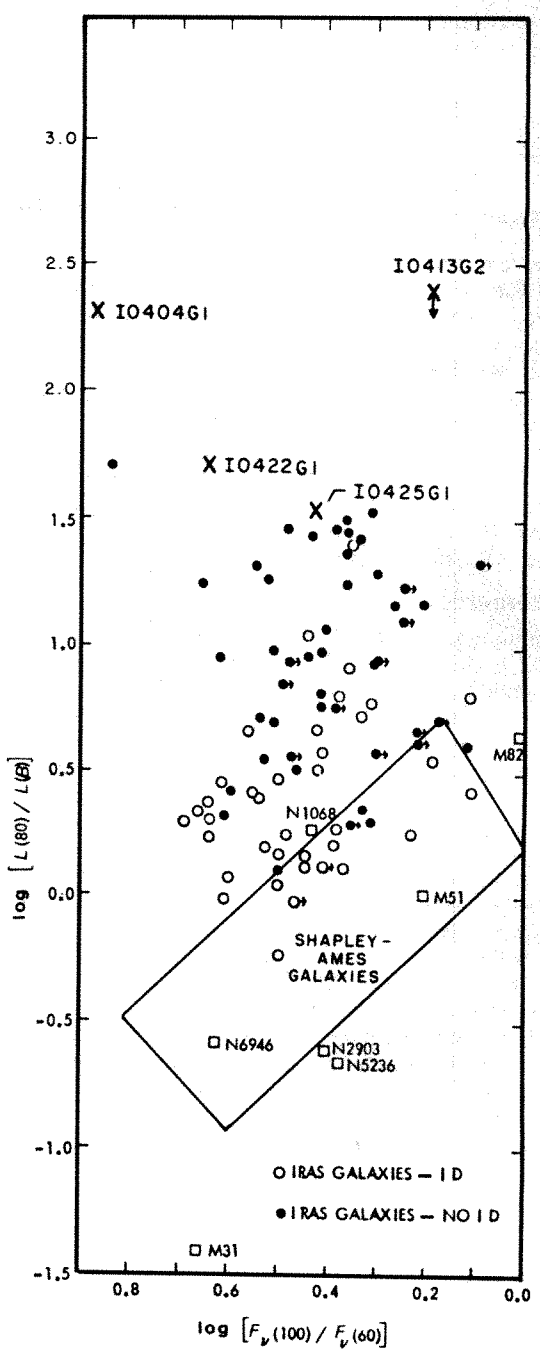

Fig. 2 The ratio of luminosity at 80 μm to that in the blue is plotted against the flux density ratio at 100–60 μm. ×, Galaxies studied here; ○, catalogued and ●, uncatalogued galaxies in the IRAS mini-survey[5]. The box encompasses the location of most Shapley–Ames galaxies[10]. Some selected nearby bright galaxies are also individually labelled.

the Kron–Cousins system, which we use for the photometry. Of the five IRAS sources we have identified, three have an estimated $R \leq 17.5$ mag, while two have an estimated $R \sim 19$ mag. For the typical error ellipse area of ~0.5 arc min^2, we find a probability of ~0.03 for random coincidence if $r_F \leq 17.5$ mag, which becomes ~0.16 for $r_F \leq 19$ mag. On an individual basis, then, the probability of chance background contamination is low; but, on the other hand, we can expect to find one interloper having $r_F \leq 19$ mag given six total surveyed fields. Hence, one of our suggested identifications may be spurious. This question can be further considered when more accurate IRAS source positions become available, but we believe that at present the source identifications given above are in most (and possibly all) cases correct.

We conclude that distant galaxies probably dominate the sample of unidentified point sources presented by Houck *et al.*[1], rather than galactic objects or some previously undiscovered type of source. Indeed, we have located galaxian counterparts for all five of the (remaining) RA 4 h Houck *et al.*[1] point sources.

Table 1 shows positions accurate to ~1 arc s for the four source identifications having new imaging data. These were measured from our CCD frames in relation to secondary positional standards, whose coordinates were in turn determined relative to nearby Smithsonian Astrophysical Observatory (SAO) Catalogue stars on the POSS plates. Figure 1 shows that correspondence with the Houck *et al.*[1] positions is generally reasonable (the one exception being 0422+009). In the lower part of Table 1, we give positions for other galaxies marked in Fig. 1.

The four galaxy identifications in Fig. 1 all seem to be members of small clusters, groups, or pairs, and at least two of these objects seem morphologically peculiar and may be interacting with nearby neighbours. This could be an important clue for understanding the extreme IR properties of these spirals. Interestingly, a high fraction of interacting neighbours was also found for the "IR galaxies" studied by Soifer *et al.*[5].

Photometry

RI photometry (on the Kron–Cousins system) is presented in Table 1 both for the source identifications and for the nearby companions. The photoelectric standardization again followed common procedures[2]. Magnitudes for both the standard stars and program objects were measured using an aperture photometer program at Dominion Astrophysical Observatory, and the estimated photometric accuracy of the data is~0.05 mag. The galaxy magnitudes quoted were found by first calculating brightness within successively larger apertures until either a stable magnitude was reached, or interfering objects were encountered. The latter was a problem only for 0413+122, and for all but the galaxies in this field, the magnitudes in Table 1 can be considered indicative of total magnitudes.

The $R-I$ colours of the source identifications, corrected for galactic reddening, range from 0.70 to 0.76. (Reddening corrections have been calculated using van de Hulst curve number 15 interpolated to the effective wavelengths of our filters; and for galactic extinction we adopt the colour excesses listed by Houck *et al.*[1].) Comparison with the $R-I$ colours of nearby disk galaxies is hampered by the fact that such photometry appears only rarely[6–8], and what does exist must be converted with some uncertainty from the Johnson to Kron–Cousins system[9]. Nevertheless, it seems that the $R-I$ colours of our IRAS source counterparts are completely normal. For example, the transformed spiral colours measured by Johnson[6] range from 0.66 to 0.78. The *RI* colours for the other objects listed in the lower part of Table 2 also do not appear unusual, except perhaps for the rather red colour of galaxy number 3 in the 0404+101 field.

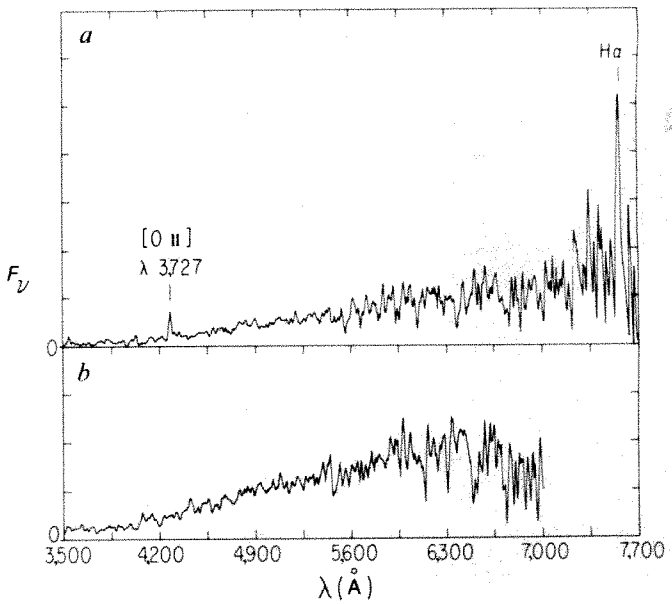

Fig. 3 MMT Reticon spectra of *a*, 0422+009 and *b*, 0425−012. The flux scale is linear. The spectrum in *b* has not been plotted longward of 7,000 Å, where it is severely degraded by noise.

The $R-I$ colour primarily measures the old giant population common to all galaxies, and apparently has little sensitivity to other galaxian components. In particular, Johnson's $R-I$ colour of 0.66 for the proto-typical starburst galaxy M82 falls within the range of colours covered both by his spirals and ellipticals. (Note also the *k*-correction for $R-I$ remains <0.05 mag for $z<0.2$; M. Lebofsky, personal communication.) Hence, the *RI* colours provide little insight into the physical nature of the IR sources.

With the present data we can, however, estimate the ratio of luminous output at 80 μm to that in the blue for comparison with the similar quantity calculated by de Jong *et al.*[10] for Shapley–Ames galaxies and by Soifer *et al.*[5] for IR galaxies from the IRAS mini-survey. For this, we need to make three corrections: one for galactic extinction, one for internal absorption, and one for conversion from *R* to *B* magnitudes. It is probably the second of these which introduces the greatest uncertainty into the results. The first correction has already been mentioned. For the third correction we adopt $B-R=1.3$ mag, a value appropriate to face-on spirals in the catalogue of Bothun *et al.*[11]. (For 0425−012 we additionally assumed an $R-I$ value of 0.9 mag.)

The correction for internal absorption (A) is more problematic. Given the limited and exotic nature of our data, application

of any of the standard absorption prescriptions seems difficult. We have instead chosen to adopt $A_R = 0.3$ mag (or $A_B = 0.5$ mag). This value is typical for the 'average' inclined spiral, if we attribute the difference in the mean spiral $B-R$ colour of 1.5 mag from the face-on spiral colour of 1.3 mag in the catalogue of Bothun *et al.*[11] as arising from internal reddening. The resulting implied colour excess $E(R-I) \sim 0.1$ mag is not inconsistent with our measured colours, but we stress that because the galaxies studied here may be quite optically thick in dust, any adopted correction must be viewed with caution.

Our estimated corrected B magnitudes for the IRAS source identifications are given in Table 1, together with the (interpolated) 80-μm fluxes from Houck *et al.*[1], and the resulting $L(80\ \mu m)/L(B)$ ratios. The last cover a range of extraordinarily large values, from 35 to 251. We consider the value of 251 for 0413+122 an upper limit, though, because both the magnitude listed for the object is a probable underestimate of the total magnitude, and also because the other two galaxies within the IRAS beam may contribute significantly to the IR flux. Even if the flux is equally shared, though, a still impressive lower limit of $L(80\ \mu m)/L(B) \sim 80$ would hold for the triplet system. Figure 2 shows the IR-to-blue luminosity ratio plotted against the ratio of flux density at 100–60 μm for the galaxies studied here and for those from Soifer *et al.*[5] and de Jong *et al.*[10]. As can be seen, only one object from these other surveys falls within the high range of IR-to-blue luminosity ratio encompassed by the present sample. [Comparison with and between the de Jong *et al.*[10] and Soifer *et al.*[5] results is a little confused by the differing precepts these authors adopt for galactic reddening and internal absorption corrections. For example, applying the procedures of Soifer *et al.*[5] to M31 yields for this spiral $\log[L(80\ \mu m)/L(B)] = -1.09$, a value more in line with other low IR emitting galaxies (see Fig. 2).]

Spectroscopy

Recently, we have obtained spectra for two of the identified sources, 0422+009 and 0425−012, using the Multiple Mirror Telescope (MMT) and the 'big blue' photon counting Reticon system. Our flat-fielded, sky-subtracted, and flux-calibrated results are presented in Fig. 3. Both objects were observed on two nights (29–30 and 30–31 January 1984) for a combined integration time of 40 min for 0422+009 and 30 min for 0425−012. The 1×3 arc s slit used yielded an instrumental resolution of 5 Å, although the spectra plotted in Fig. 3 have been smoothed to ~20 Å resolution.

Two emission lines are visible in the spectrum of 0422+009, which we identify with [O II] λ3,727 and Hα. These yield a redshift $z = 0.1544 \pm 0.0005$. For a Hubble constant $H_0 = 80\ km\ s^{-1}\ Mpc^{-1}$, we obtain an estimated absolute blue magnitude of $M_{B_0,i} \simeq -20.5$, a value sufficiently bright to suggest that the large IR-to-blue luminosity ratio primarily reflects excess IR emission, and not simply great dimming of starlight by dust. At our original instrumental resolution, the [O II] line is unresolved. However, we do appear to resolve Hα, and obtain a formal FWHM value of $\sim 600\ km\ s^{-1}$, but the uncertainty in this result is large due to the poor signal-to-noise ratio. Perhaps surprisingly, no obvious emission features are present in the spectrum of 0425−012; nor is the signal-to-noise ratio adequate to show believable absorption features.

Our spectrum of 0422+009 has other notable attributes. First, it does not fit easily into any of the various empirical classification schemes that have been developed for extragalactic line emission regions[12,13]. In particular, the weakness and/or absence of both Hβ and [O II] λ5,007 is atypical of giant H II region spectra. Nor is there much evidence for the presence of [N II] λ6,584, one of the characteristic lines seen in a low excitation class of objects Heckman calls "liners"[12]. The large ratio of Hα to [O II] that is seen implies considerable reddening, a not unexpected result. The presence of line emission is itself not so unusual; for instance, about one-third of all nearby bright galaxies are liners, which are found among both spirals and ellipticals[12]. However, an intriguing aspect of the 0422+009 spectrum involves the large rest frame equivalent widths of [O II] λ3,727 (50 Å) and Hα (90 Å). Given the object's redshift, if the line-emitting region is confined solely to the nucleus, then even a conservative correction for background continuum flux would yield equivalent widths comparable with those seen in many nearby Seyferts. Clearly, long-slit spectra of high signal-to-noise ratio would help to clarify the nature of the excitation mechanism involved.

Powering the IR emission

The IRAS sources identified here seem to be extreme examples of the IR galaxies discussed by Soifer *et al.*[5]. We now briefly consider what underlying physical process powers the enormous IR output of these systems.

One possibility involves star formation bursts enshrouded by optically thick dust. Indeed, the seemingly high fraction of interacting galaxies found both here and by Soifer *et al.*[5] may (at least in some cases) provide the triggering mechanism for the outbursts. Further evidence for a thermal rather than non-thermal origin for the IR emission comes from recent 1.5 GHz Very Large Array (VLA) observations by R. Elston (personal communication), who observed but could not detect (with a 0.6 mJy 3-σ upper limit) three IR galaxies from Soifer *et al.*[5] having $L(80\ \mu m)/L(B) \sim 20$.

Rieke *et al.*[14] have presented a detailed starburst model for M82, and scaling their results up to match the properties of the IRAS source 0422+009 discussed above leads to some interesting consequences. First, the absolute IR luminosity of 0422+009 is ~35 times that of M82, and to produce such a flux from star formation, roughly 10% of the stellar mass in 0422+009 must participate in the burst. In such a case, however, non-thermal supernova remnant emission ought to be detectable in the radio[15]. Furthermore, the implied star formation rate in 0422+009 would be $100\ M_\odot\ yr^{-1}$. Our measured Hα flux of $(15 \pm 5) \times 10^{-15}\ erg\ cm^{-2}\ s^{-1}$, crudely estimated by normalizing the continuum flux in Fig. 3*a* to our *R*-band CCD photometry, is not inconsistent with such a high rate though. In fact, adopting the Hα flux calibration of Kennicutt[16] yields an estimated lower limit to the star formation rate of $\sim 15\ M_\odot\ yr^{-1}$, and correcting this value upwards for a reasonable 2–3 mag of internal absorption would produce the requisite rate.

One alternative power source might be an embedded active galaxy nucleus, such as a Seyfert nucleus, as proposed by Antonucci and Olszewski[15]. Our data provide little constraint on this possibility. However, future spectroscopic and radio observations of robust IR galaxies such as those discussed here should be able to distinguish between the starburst and active nuclei models.

We have benefitted from conversations with several people, including C. Beichman, R. Elston, F. Low, G. Neugebauer, H. Spinrad, M. Phillips, G. Bothun and R. Antonucci. We also thank K. Cook for assistance with the data reduction. This work was partially supported by NSF grant AST 81-17365. Research reported here used the MMT Observatory, a facility operated jointly by the University of Arizona and the Smithsonian Institution. M.A. and E.W.O. are visiting astronomers at Cerro Tololo Interamerican Observatory, operated by AURA, Inc., under contract with the NSF.

The complete 1,210-amino acid sequence of the human epidermal growth factor (EGF) receptor precursor, deduced from cDNA clones derived from placental and A431 carcinoma cells, reveals close similarity between the entire predicted v-erb-B mRNA oncogene product and the receptor transmembrane and cytoplasmic domains. A single transmembrane region of 23 amino acids separates the extracellular EGF binding and cytoplasmic domains. The receptor gene is amplified and apparently rearranged in A431 cells, generating a truncated 2.8-kilobase mRNA which encodes only the extracellular EGF binding domain.

EPIDERMAL growth factor (EGF), a potent mitogenic polypeptide, initiates cellular responses by binding to specific receptors on the surface of target cells (for reviews see refs 1, 2). Like several other growth factors, the binding of EGF to its cell surface receptor triggers a cascade of intracellular events, including induction of a tyrosine kinase activity intrinsic to the EGF receptor[1-5]. Shortly after binding, the EGF–receptor complexes are localized in clathrin-coated regions of the plasma membrane and are then internalized by the cell.[6,7].

How these events lead to the stimulation of DNA synthesis and cellular proliferation are unknown. The recent observation that the receptors for platelet-derived growth factor (PDGF)[8,9], insulin[10,11] and insulin-like growth factor (IGF-I)[12], are also tyrosine-specific protein kinases suggested that tyrosine phosphorylation might be an important early step in triggering proliferation. The tyrosine-specific protein kinase activity of several retroviral transforming proteins (reviewed in ref. 13) has led many workers to search for a connection between growth factor receptors and transforming proteins. In their analysis of partial protein sequences, Downward *et al.*[14] demonstrated close similarity between the EGF receptor and the avian erythroblastosis virus (AEV) v-*erb-B* transforming protein[15]; evidence was presented suggesting that the viral transforming protein contained only the transmembrane and tyrosine kinase domains of the avian EGF receptor, and lacked most of the extracellular domain responsible for EGF binding. It was proposed that transformation of cells by AEV was the result, at least in part, of expression of a truncated EGF receptor molecule lacking the extracellular control domain[14].

We have now investigated EGF receptor expression in placental and A431 carcinoma cells[16]. A431 cells were chosen because they show two unusual features. First, they possess about 10–50 times more EGF receptors on their surface than most other cell types[16,17]. These high EGF receptor levels seem to be associated with the presence of a chromosomal translocation (M4) involving chromosome seven[18]. Second, their mitogenic response to EGF does not correlate with their increased EGF binding capacity. Thus while low concentrations of EGF stimulate their proliferation, EGF concentrations mitogenic for many cell lines inhibit proliferation of A431 cells[19,20]. It was therefore of great interest to investigate the genetic basis for the unusual features of this tumour cell line.

The complete amino acid sequence derived from human EGF receptor cDNAs from placental and A431 cells confirms the findings of Downward *et al.*[14], and matches partial amino acid sequences obtained from purified placental and A431 cell EGF receptor protein. Our findings also demonstrate that the EGF receptor gene is amplified in A431 cells. Furthermore, we describe the detection of an aberrant A431-specific chimaeric mRNA molecule which consists of a fragment of EGF receptor coding sequences recombined with sequences of unknown origin and function. This aberrant mRNA encodes only the external EGF binding domain of the receptor and lacks sequences which would encode the transmembrane and cytoplasmic domains. Expression of a truncated domain similar to the erb-B polypeptide found in AEV transformed cells[14] was not detected but its existence at low concentrations cannot be excluded.

Partial amino acid sequence

Receptor purified by immunoaffinity chromatography followed by gel permeation HPLC in guanidine after reduction and alkylation to cleave disulphide bonds was digested with trypsin and the peptides fractionated by preparative reverse-phase HPLC[14]. The purification and partial sequence analysis data of these peptides are shown in Fig. 1. The amino-terminal sequence of the intact receptor was deduced for a short stretch of 8 residues (see Fig. 1*v*). These partial amino acid sequences were found to be identical (apart from 2 residues) to those subsequently established by nucleotide sequencing of cDNA.

EGF receptor cDNA clones

Oligo(dT)-primed cDNA libraries were prepared from mRNAs derived from human placental tissue and epidermoid carcinoma (A431) cells using the λgt10 vector system[21]. As analysis of EGF receptor biosynthesis in A431 cells had suggested a polypeptide

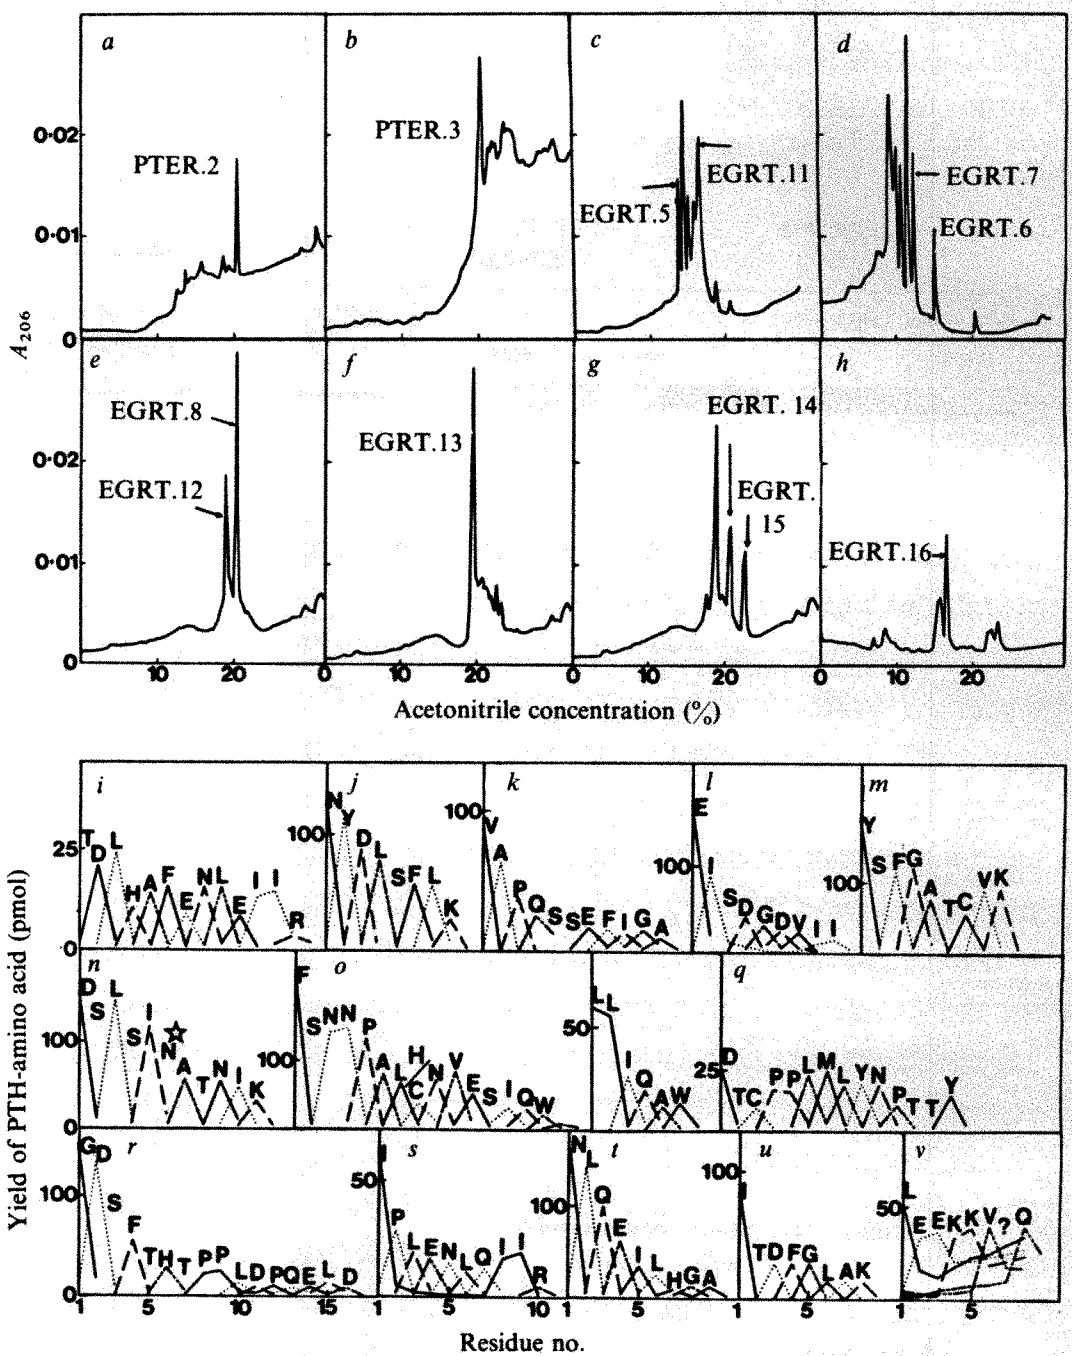

Fig. 1 EGF receptor peptide sequence analysis. *a–h*, Purification of peptides from the EGF receptor for sequence analysis. EGF receptor was purified from human placenta (*a*, *b*) or A431 human epidermoid carcinoma cells (*c–h*) using monoclonal antibody R1 (ref. 42); it was then fully reduced and alkylated, run on a gel permeation column, digested with trypsin and the resulting peptides fractionated by reverse-phase HPLC at *p*H 2.0, as described previously[14]. Fractions corresponding to optical density peaks in the first reverse-phase separation were further purified by reverse-phase HPLC on a Synchropak RPP C_{18} column (4.6 × 75 mm; Synchrom, Linden, Indiana) equilibrated in 10 mM ammonium acetate buffer, *p*H 6.5. A linear gradient of 0–45% acetonitrile over 45 min was used to elute peptides, flow rate 1 ml min^{-1}. The absorbance of the eluate was monitored at 206 nm and 0.5 ml fractions were collected. The figure shows the resulting chromatograms when the following fractions from the *p*H 2.0 fractionation were run: *a*, tryptic peptides from the placental EGF receptor eluting at 19% acetonitrile; *b*, placental peptides eluting at 22% acetonitrile; *c*, tryptic peptides from the A431 cell EGF receptor eluting at 21% acetonitrile; *d–h*, A431 peptides eluting at 18, 24, 26, 28 and 22% acetonitrile, respectively. *i–v*, Sequence analysis of peptides from the EGF receptor. Sequence determination was carried out as described[14]. The figure shows the yield of PTH derivatives of amino acids at each cycle of the Edman degradation for the peptides: *i*, PTER.2; *j*, PTER.3; *k*, EGRT.3 (for which the full purification has been described elsewhere[14]); *l*, EGRT.5; *m*, EGRT.6; *n*, EGRT.7; *o*, EGRT.8; *p*, EGRT.11; *q*, EGRT.12; *r*, EGRT.13; *s*, EGRT.14; *t*, EGRT.15; *u*, EGRT.16. *v*, The amino-terminal sequence for the whole EGF receptor molecule from A431 cells. The protein was treated with 0.05% SDS before sequencing. The seventh residue could not be assigned. ☆, The sixth residue of EGRT.7 was assigned from amino acid analysis of the peptide; the absence of asparagine-PTH at this sequencer cycle suggests that the residue is glycosylated.

backbone of molecular weight (MW) ~ 138,000 (ref. 22), at least 3,500 base pairs (bp) of coding sequence would be required, thus a sizing step was introduced to enrich for cDNA molecules greater than 2,000 bp long. For screening purposes a 51 bp-long DNA hybridization probe (Fig. 2*a*) was designed and synthesized[23] on the basis of a preliminary partial amino acid sequence of an A431 EGF receptor cyanogen bromide (CNBr) peptide (EGRC.1)[14]. Previous studies have shown that the use of a single long probe for clone screening under conditions of low stringency is often superior to the more commonly used technique which involves screening with pools of short oligonucleotide probes[24–26].

Initial screening of the placental cDNA library (2×10^5 clones) yielded seven distinct positive clones as judged by *Eco*RI restriction endonuclease mapping and Southern hybridization[27] with our synthetic probe. The longest fragment (1.4 kilobases, kb) of clone λ HER-P3 was sequenced using the dideoxynucleotide chain termination procedure[28–30]. The resulting sequence confirmed the presence of a region of similarity with our probe which, despite two errors in the preliminary determination of the amino terminus of the CNBr peptide, differed at only five positions from the sequence of the cloned cDNA (Fig. 2*a*, *c*). A second sequence analysis of this peptide gave the amino-terminal sequence Gly-Asp- (see ref. 14) and reinspection of these data revealed a trace of PTH-Asp at step 1 supporting the sequence found in analysis of cDNA clones. Comparison of the

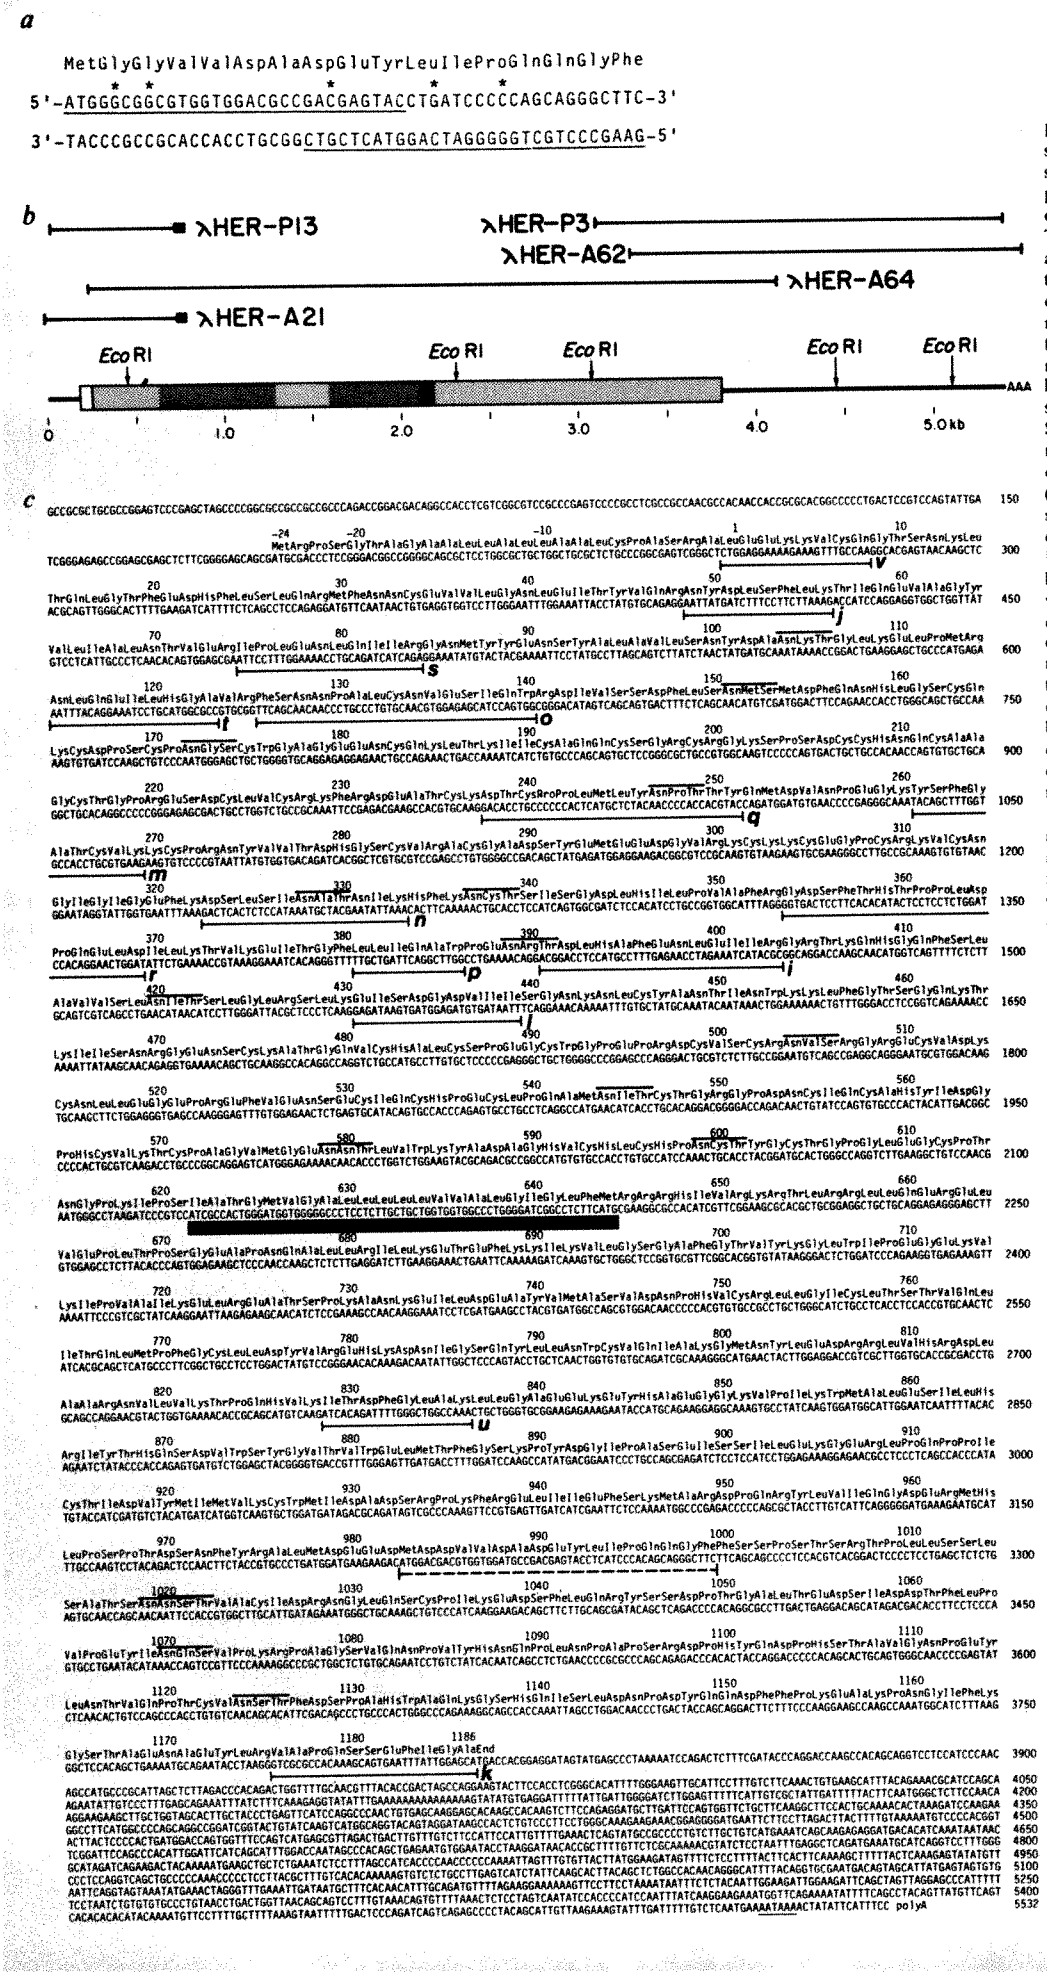

Fig. 2 EGF receptor cDNA nucleotide sequence and predicted amino acid sequence. *a*, The nucleotide sequence of probes based on the amino acid sequence of a CNBr peptide of A431 EGF receptor. The initial amino acid residue was assumed to be methionine since the peptide was generated by cyanogen bromide cleavage[14]. The DNA sequence was designed on the basis of published codon usage frequencies[57]. Two overlapping 30 residue-long oligonucleotides (underlined) from coding and non-coding strands were chemically synthesized[23]. *b*, Schematic representation of human EGF receptor cDNA clones. Overlapping clones from placenta ("P") and A431 ("A") epidermoid carcinoma cells used in sequence determination and a schematic diagram of the complete cDNA structure. Untranslated sequences are represented by a line, coding sequences are boxed. The white portion represents sequences which encode the signal peptide; hatched regions code for the mature receptor, dark hatched regions are high in cysteine residues (see text). The black region demarcates the coding region for the putative transmembrane domain. Black boxes on the 3′ ends of λ clones indicate that these clones were obtained by specific priming (complementary sequence at positions 757–780). *c*, Nucleotide and predicted amino acid sequence of EGF receptor. Nucleotides are numbered at the right; amino acids are numbered throughout. Peptide sequences derived from purified receptor preparations are underlined and labelled according to Fig. 1(*i*–*u*). The peptide underlined with a broken line was that used to design a long synthetic DNA probe (see Fig. 2*a*). Sites of potential asparagine-linked glycosylation are overlined; the putative transmembrane region is demarcated by a black bar. The AATAAA box close to the polyadenylated 3′ end of the mRNA is underlined.

Methods: *a*, The probe was radiolabelled by first phosphorylating the synthetic 30-mers using T4 polynucleotide kinase (PL Biochemicals) and [γ-^{32}P]ATP (Amersham, >5,000 Ci mmol^{-1}) followed by annealing the kinased single strands and filling in the complementary sequences using *Escherichia coli* DNA polymerase I (Klenow fragment) with [α-^{32}P]dCTP and [α-^{32}P]dATP (Amersham) yielding probes of 5×10^8 c.p.m. per μg specific activity. Hybridization was carried out in conditions published elsewhere[24]. Filters were washed at 45 °C with 0.2 × SSC, 0.1% SDS. Asterisks denote nucleotides of the synthetic probe which did not match the sequence of the isolated clone. *b*, Cytoplasmic mRNA from total human term placental tissue and A431 cells were isolated in the presence of RNase inhibitors following standard protocols[58]. cDNA synthesis[59], cloning into a λ vector (λgt10)[21], and plaque screening[60] were carried out according to published procedures. *c*, Nucleotide sequence analysis was carried out by subcloning suitable restriction fragments from our recombinant λ clones into M13-based cloning vector (M13mp10 and M13mp11[29]) followed by primed DNA synthesis on single-stranded DNA templates in the presence of dideoxynucleoside triphosphates[28,30].

Fig. 3 Comparison of EGF receptor with v-*erb-B* predicted amino acid sequences. Only non-matching amino acids are shown for v-*erb-B*. The bracket on the first line indicates the start of the v-*erb-B* sequence[15]. The putative transmembrane region is boxed; the arrow demarcates the autophosphorylated tyrosine residue in pp60^{src} (ref. 61). Asterisks indicate residues conserved between the receptor sequence and several members of the *src* gene family (*src, fes, yes, fps*). Hyphens (gaps) have been introduced for optimal alignment. The C-terminal tetrapeptide of the v-*erb-B* sequence derived from the AEV *env* gene is underlined[15].

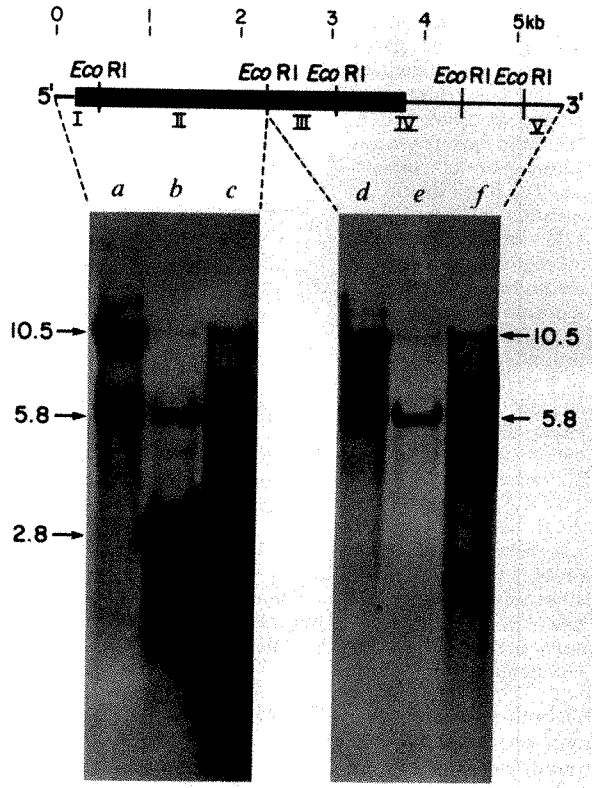

Fig. 4 Northern blot analysis of cytoplasmic placental and A431 mRNAs. Lanes *a* and *d*, placental mRNA; *b* and *e*, A431 mRNA; *c* and *f*, mRNA from a second, independently passaged line of A431 cells. Dashed lines indicate the regions of the schematically depicted cDNA giving rise to the hybridization patterns shown. Numbers on the left and right indicate sizes (in kb) of major mRNA bands. Roman numerals denote *Eco*RI fragments used as hybridization probes (see below).

Methods: A431 cells were grown in Dulbecco's modified Eagle's medium containing 10% fetal calf serum in an atmosphere of 10% CO_2–90% air at 37 °C. Cytoplasmic mRNA isolated from frozen placental tissue after pulverization in liquid N_2 and from fresh A431 cells[58] was separated (2 μg per lane) on 1% agarose formaldehyde gels and transferred to nitrocellulose filters as described by Lehrach *et al.*[36]. Rat liver ribosomal RNA (18S = 1,874 nucleotides; 28S = 4,718 nucleotides; I. Wool, personal communication) and 42S vesicular stomatitis virus RNA (~12 kb) were used as size markers. Nitrocellulose filters were hybridized under high-stringency conditions with radiolabelled *Eco*RI fragments (I = 293 bp; II = 1,838 bp; III = 768 bp; IV = 1,373 bp; V = 432 bp) derived from clones λHER-A62 and λHER-A64.

complete sequence of the 2.3-kb cDNA clone λHER-P3 with the nucleotide sequence of the oncogene v-*erb-B*[15] showed that it coded for 243 carboxy-terminal amino acids of the receptor followed by a termination codon and about 1,600 bp of presumably 3′-untranslated sequences lacking a poly(A) homopolymer stretch (see Fig. 2*b*).

Using the 1.4 kb *Eco*RI fragment of λHER-P3 as a probe, 21 clones were isolated from an A431 cDNA library and characterized by *Eco*RI restriction analysis. Clones λHER-A62 and λHER-A64 were found to contain overlapping DNA fragments, which together spanned a stretch of 5.2 kb (Fig. 2*b*) of DNA. Complete sequence analysis revealed an open reading frame coding for 1,186 amino acid residues, including carboxy-terminal sequences identical to λHER-P3 and very similar to v-*erb-B* transforming protein. Clone λHER-A62 was found to contain the complete 3′-untranslated region (1,913 bp), as evidenced by the presence of an AATAAA sequence[31] followed by a poly(A) tail 15 nucleotides downstream.

The amino acid sequences of 13 tryptic peptides as well as those of the 6 previously reported[14] were located within the predicted amino acid sequence (see Figs 1, 2*c*). Only two differences were detected between the 230 amino acid residues determined by peptide sequencing and those derived from analysis of the cloned cDNA (Cys as opposed to His at position 133). Reinspection of amino acid sequencing data revealed a failure to distinguish between Cys and His in peptide EGRT.8 and to assign amino-terminal Asp in peptide EGRC.1. Remarkably, clone λHER-A64 starts with a nucleotide sequence encoding the amino acid sequence NH_2-Leu-Glu-Gly-Lys-Lys, which is identical to the amino-terminal sequence of the A431 receptor polypeptide (see Figs 1*b*, 2*c*).

In order to obtain missing sequences upstream from those which encode the amino-terminus of the mature protein, an A431 cDNA library generated by priming with a 24 nucleotide-long synthetic oligomer (see Fig. 2 legend) was screened with the 5′-most *Eco*RI fragment of λHER-A64. Clone λHER-A21 perfectly matched the sequence of λHER-A64 and extended it 260 bp further upstream. The new sequence contained coding information for an additional 24 predominantly hydrophobic amino acids, including the presumptive initiator methionine. This sequence probably represents the EGF receptor signal peptide which is necessary for transfer of the nascent polypeptide into the lumen of the endoplasmic reticulum. Basic and polar amino acid residues flank the hydrophobic core of the amino-terminal 24-amino acid sequence, a common structural feature of signal peptides. Furthermore, within the 186 bp of 5′-untranslated sequence, an in-frame termination codon is located 36 nucleotides upstream (Fig. 2*c*), supporting the assignment of residue −24 as the initiation methionine of the 1,210 amino acid-long EGF receptor precursor polypeptide. Placental EGF receptor clones were generated in an analogous priming experiment. Clone λHER-P13 (Fig. 2*b*) was characterized and matched perfectly the sequence of λHER-A21. These data show

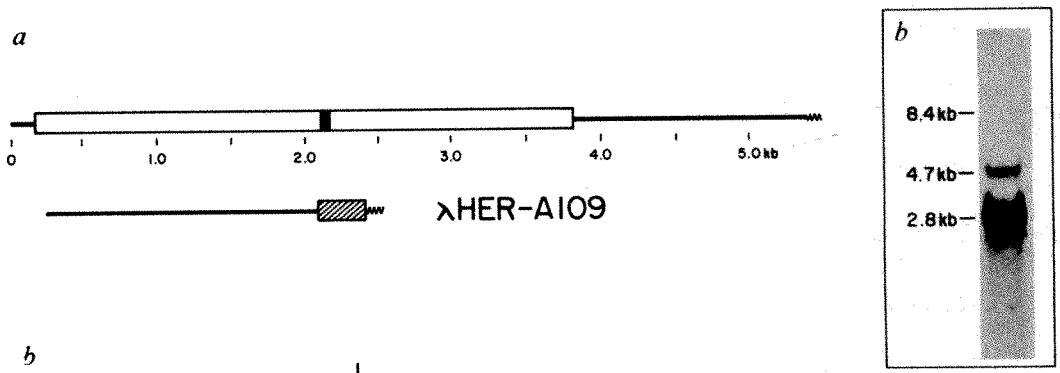

Fig. 5 Structure of an A431 cell-specific cDNA variant. *a*, Schematic map of normal (top) and variant (bottom) cDNA. The solid box represents transmembrane sequences. The black line in the variant cDNA clone λHER-A109 represents the region of identity with the normal EGF receptor sequence; the cross-hatched box represents a region of unknown origin. ~, Poly (A) tails. *b*, Northern blot analysis using a probe derived from the non-homologous region of variant cDNA clone λHER-A109. A 260-bp *Hpa*I–*Eco*RI fragment was used as radioactive probe (10^8 c.p.m. μg^{-1}). Blots were exposed for 72 h. Sizes of mRNAs are shown in kb. 28S (4,718 nucleotides) and 18S (1,874 nucleotides) ribosomal RNAs were use as size standards. No hybridization was detected in a parallel experiment with placental mRNA. *c*, Nucleotide sequence of cloned cDNA from λHER-A109. The start of the cDNA is shown, together with the junction of non-homology to EGF receptor cDNA and the entire non-homologous 3′ end.

that both placental and A431 receptors are not synthesized as larger precursor molecules aside from the signal peptide; the unmodified precursor and mature polypeptides have predicted molecular weights of 134,300 and 131,360, respectively. These values are in good agreement with the molecular weight (138,000) determined for EGF receptor synthesized in tunicamycin-treated A431 cells, where *N*-linked glycosylation does not occur[22].

Human EGF receptor/v-*erb-B* homology

Partial amino acid sequence analysis of peptides obtained from placental and A431 cell EGF receptor preparations had demonstrated that the EGF receptor matches, in part, the amino acid sequence of the product of the v-*erb-B* oncogene from avian erythroblastosis virus (AEV-H[14,15]). Availability of the complete EGF receptor sequence derived from cloned cDNA now permits a detailed sequence comparison. Figure 3 shows an alignment of the 604 residue-long v-*erb-B* sequence[15] with 631 carboxy-terminal amino acids of the human EGF receptor. Extensive amino acid sequence homology is detected over a 376 residue-long core region, beginning at the cytoplasmic junction with the transmembrane domain present in both sequences; 95% of the residues in this region are conserved, which is highly significant considering the evolutionary distance between birds and humans, and therefore probably represent sequences essential for the function of this domain. A 244 residue-long stretch within this region contains 60 residues (24.6%) which are conserved in other oncogenes of the *src* gene family (for clarity, only *src*, *fes*, *yes* and *fps* are shown in Fig. 3)[32]. These include the tyrosine which is the substrate for the autophosphorylation reaction of $pp60^{src}$ (refs 33, 34; Fig. 3). The equivalent region of the EGF receptor also retains the amino acid residues thought to be involved in the formation of an ATP binding site[32,35]. The extent of the sequence conservation is reduced in sequences flanking this 376-amino acid core region until, at residue 600, the v-*erb-B* sequence is fused to the carboxy-terminal tetrapeptide of the AEV *env* protein[15]. The EGF receptor sequence continues from the point of divergence at the 3′ end for another 32 amino acids. In the light of the sequence identity in the putative tyrosine specific kinase domain, it is surprising that the *erb-B* transforming protein has not been shown to possess kinase activity. This may reflect technical difficulties or could indicate that the carboxy-terminal region, in which there is less similarity between the sequences, may be important for expression of the EGF receptor kinase activity. The complete sequence further substantiates the hypothesis that v-*erb-B* oncogene sequences originated from cellular sequences which encode the avian EGF receptor[14]. As the nucleotide and hence the amino acid sequence of the avian EGF receptor is unknown, the relevance of particular amino acid differences between the human receptor and avian oncogene sequences to the transforming function of the virus remains unclear. The extent of similarity further supports our previous suggestion[14] that other oncogene products that have regions of amino acid sequence similar to v-*erb-B* and the EGF receptor, which form a group known as the *src* gene family, may be derived from cellular sequences encoding other receptors having tyrosine kinase activities such as the PDGF, IGF-I and insulin receptors.

Receptor-related mRNAs

To determine the size of the mRNA encoding the EGF receptor, Northern blot hybridization[36] experiments were done using cytoplasmic mRNA isolated from term placenta and from two independently propagated lines of A431 cells. The RNA preparations were probed with various segments of the cloned EGF receptor cDNA. Figure 4 shows that different patterns of hybridization were obtained with probes derived from sequences coding for the 5′-untranslated region and the extracellular domain as compared with probes derived from the cytoplasmic domain and the 3′-untranslated regions. In all experiments, two transcripts of 5.8 and 10.5 kb were detected in both A431 and placental RNA preparations, however the relative amounts of the transcripts differed between placenta and A431 cells, as well as between the two lines of A431 cells. Similarly, two transcripts of 12 and 9 kb have been detected in normal chicken embryo mRNA using v-*erb-B* probes[37]. These two transcripts could result from transcription of two closely related genes, or, alternatively, represent transcripts of different length from the same gene. Transcription of the mouse α-amylase and dihydrofolate reductase genes, for example, involves usage of multiple poly-(A) addition sites, generating mRNAs of variable lengths from a single gene[38,39]. Alternatively, variable splicing events could generate two mRNAs, perhaps with different function, from a single gene[40,41]. The variation in the relative levels of the two transcripts in placenta and the two A431 cell lines suggests that some specific mechanism may regulate their relative abundance depending on cell type, physiological condition or developmental state. Further experiments are needed to elucidate this phenomenon.

Probes derived from the 5′ half of the cDNA hybridize to a 2.8-kb mRNA present only in A431 cells. Compared with the

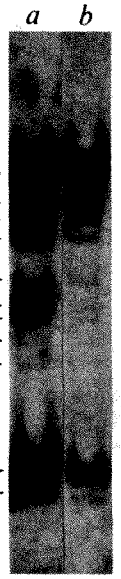

Fig. 6 Southern blot analysis of A431 (*a*) versus placental (*b*) DNA. High-molecular weight chromosomal DNA was isolated as described[58]. DNA (10 μg) was digested with excess *Eco*RI (New England Biolabs) then analysed by Southern blot hybridization. A mixture of all *Eco*RI fragments of λHER-A62 and λHER-A64 (as in Fig. 4) was radiolabelled with [α-^{32}P]dATP and [α-^{32}P]dCTP (Amersham) by the procedure of Taylor *et al.*[62]. Processed filters were exposed to X-ray film for 5 days at −70 °C using Cronex lightning plus intensifier screens. λ phage DNA was digested with *Eco*RI and *Hin*dIII was used as a size marker.

two normal mRNAs, this RNA species is overexpressed ~100-fold (Fig. 4*b*, *c*). In addition to the normal mRNA bands at 10.5 and 5.8 kb, various fainter bands are observed after long exposure times in both placenta and A431 RNA preparations (see Fig. 4 and data not shown). A 6.1-kb mRNA which is present in both A431 cells and placenta appears to be homologous to all probes used; the same is true for a placenta-specific 13-kb mRNA. Another group of mRNAs from both sources hybridizes with either 5′ (1.8 kb) or 3′ (8.9 kb) probes. Faint A431-specific hybridization signals are detected with 5′ probes at 3.3, 1.65, 1.5 and 1.3 kb in addition to the predominant 2.8-kb mRNA. These bands may represent low-abundance variant transcripts of the same gene, or possibly transcripts of other genes which are structurally related to either the entire EGF receptor or one of its major domains.

Truncated EGF receptor sequences

To characterize in detail the predominant 2.8-kb variant mRNA from A431 cells, an oligo(dT)-primed cDNA bank (>2 kb; ~10^5 clones) was screened with a 5′-specific EGF receptor cDNA probe (Fig. 4, fragment I). Of 167 positives, the three clones with the largest inserts were found by restriction enzyme analysis to be related to but distinct from clone λHER-A64. Clone λHER-A109 (2.5 kb) was sequenced and was found to be identical with our EGF receptor cDNA sequence starting at amino acid position −8 in the signal sequence and extending through almost the entire extracellular domain of the receptor. The amino acid sequence identity terminated abruptly, however, at amino acid residue 615, shortly before the transmembrane portion of the normal sequence (see Fig. 5*a*, *c*). Downstream from this residue the open reading frame continues for another 18 amino acids, followed by an opal codon (TGA) and a 548-nucleotide 3′-untranslated sequence which includes an AATAAA box 34 nucleotides upstream from the poly(A) addition site. The cDNA (λHER-A109) encodes an approximately 70,000-MW truncated EGF receptor protein which, because it contains a signal peptide but lacks the receptor transmembrane region, should be secreted by A431 cells. Monoclonal antibody R1 (ref. 42), which recognizes the extracellular domain of the EGF receptor, does in fact immunoprecipitate a secreted 115,000-MW glycopeptide, which is thought to be formed by post-translational modification of a 68,000-MW polypeptide[22]. Analogous truncation of the vesicular stomatis virus transmembrane glycoprotein by molecular cloning techniques led to secretion of a soluble protein, albeit at a severely reduced rate[43].

To establish the identity of this chimaeric cDNA, differential Northern blot hybridization experiments were carried out. Hybridization using a 185-bp *Eco*RI–*Sac*I probe derived from clone λ HER-A21, which includes only sequences upstream from the 5′ end of the variant clone λ HER-A109, resulted in a pattern identical to that seen in Fig. 4*b*, *c*. This finding, in combination with the size and sequence of clone λ HER-A109, showed that the 2.8-kb mRNA shares 5′ sequences with the 5.8- and 10.5-kb mRNAs. It is not yet clear whether transcription of these mRNAs is under the control of the same regulatory elements or whether sequence rearrangements in the 5′-flanking region of the receptor gene lead to overexpression of the 2.8-kb mRNA. A variant-specific probe (260 bp *Hpa*I–*Eco*I) derived from the 3′ end of clone λ HER-A109 hybridized to the major A431-specific 2.8-kb band as well as to fainter 4.7- and 8.4-kb bands, but not to the 5.8- and 10.5-kb mRNAs (Fig. 5*b*). Although the two less abundant (4.7- and 8.4-kb) A431-specific transcripts have the same 3′ untranslated sequence as our chimaeric cDNA clone λ HER-A109 and therefore could have engendered the cDNA, since neither of them showed homology with various EGF receptor gene sequences, we conclude that our chimaeric cDNA was derived from the 2.8-kb mRNA and that the 4.7- and 8.4-kb mRNAs probably represent transcripts from the parental gene which contain the 3′ region of the 2.8-kb mRNA.

Gene amplification

A431 epidermoid carcinoma cells express about 10–50 times more EGF receptors on their surfaces than most other cell types[16,17]. The remarkably high EGF binding capacity of these cells seems to be correlated with the presence of chromosomal translocations involving chromosome 7 (ref. 18), which is known to carry the EGF receptor gene[44,45]. In addition to the two translocated fragments of chromosome 7 (M4 and M14), A431 cells contain two copies of the normal chromosome 7 (ref. 18). To investigate further the genetic basis for the high EGF receptor levels in these cells, we compared A431 cell chromosomal DNA with DNA from placenta and other normal tissues. Assuming that the A431 cell chromosomal translocations described by Shimizu and Kondo[18] involve the entire EGF receptor gene, the signal in Southern hybridization experiments for A431 DNA was expected to be twice that detected for DNA from placenta and other human tissues. Figure 6 shows an autoradiograph of a Southern blot hybridization analysis of equal amounts of *Eco*RI-digested A431 (lane *a*) and placenta (lane *b*) DNAs. On the basis of densitometric quantification we estimate that the EGF receptor gene is amplified 15–20 times in A431 cells compared with DNA from normal diploid cells. Variable intensities of hybridization signals were observed for different bands within one lane, which may be due to different factors such as efficiency of transfer and binding to nitrocellulose, co-migration of hybridizing DNA fragments and the use of a mixed probe consisting of five DNA fragments of different size (see Fig. 6 legend). The highly selective conditions used in the hybridization experiments excluded cross-hybridization to related but non-identical sequences. Based on more detailed Southern hybridization experiments using various regions of the cDNA to probe separate blots, we estimate that the gene coding for the 5.8-kb EGF receptor mature transcript is greater than 50 kb in size (data not shown).

Our data suggest that various segments of the entire gene are amplified to the same extent. Furthermore it appears that the 8.9-kb hybridization signal obtained with A431 DNA (Fig. 6, lane *a*) is due to sequence rearrangements, since it is not present in placental and other normal DNAs (Fig. 6 and unpublished results). Additional indications of sequence rearrangements affecting the amplified receptor gene and its flanking regions have been detected in genomic Southern hybridization experiments using the 3′ nonhomologous sequence of clone λHER-A109 as a probe (A.U., in preparation).

Discussion

We have presented here for the first time the complete amino acid sequence of a cell surface receptor for a peptide ligand—the mitogen EGF.

Inspection of the receptor's predicted primary sequence reveals a stretch of 23 predominantly hydrophobic amino acids

(residues 622–644) which contains only a single amino acid with a side chain capable of hydrogen bonding. This sequence, in an α-helical configuration, could span the lipid bilayer and the group of basic residues immediately C-terminal (residues 89–101) are likely to interact with the phospholipid head groups in the membrane. It is unlikely that the external domain of the receptor contains regions that cross the lipid bilayer since in A431 cells a truncated receptor resulting from gene rearrangement and consisting of almost the entire external domain is secreted. The cytoplasmic domain may interact with the lipid bilayer but at regions with different structural features from those of the 23-amino acid transmembrane domain. The receptor therefore can be divided into two functional domains—an extracellular one of 621 amino acids and a cytoplasmic domain of 542 amino acids—linked by a short transmembrane region.

The extracellular domain would contain the EGF-binding site. This domain contains 12 of the 16 possible sites for asparagine-linked glycosylation (Asn-X-Ser or Asn-X-Thr). It is likely that the majority of these sites are indeed modified since Mayes and Waterfield[22] have shown that 11 sites are glycosylated in the precursor of the secreted external domain of the molecule.

A particularly striking feature of the receptor concerns the distribution of cysteine residues between the extracellular and cytoplasmic domains. The cytoplasmic domain of 542 amino acids contains nine cysteine residues (~2%), a value well within the range of most cytoplasmic proteins. The extracellular domain of 621 amino acids, however, contains 51 cysteine residues, most of which are concentrated within two regions of ~170 amino acids located at positions 134–313 and 446–612 (see Fig. 2*c*). Alignment of these cysteine-rich sequences with one another reveals similarities in the spacing of the individual cysteine residues, possibly reflecting the involvement of these residues in the formation of two repeated structures and a common evolutionary origin by gene duplication for this part of the receptor. We do not yet know whether these cysteine residues are all disulphide-bonded.

The cytoplasmic domain undoubtedly contains the tyrosine-specific protein kinase activity and has the stretch of amino acid sequence (approximately residues 690–940) that is shared by transforming proteins of the *src* family.

The question remains, how do the domains function in signal transduction across the membrane? If, as we suggest, the EGF receptor polypeptide crosses the membrane only once, then a signal must be transduced through this region unless two or more receptor molecules are involved or an additional polypeptide(s) mediates the response to EGF. What could be the nature of the signal? Since EGF induces rapid changes in ion movements[3] it is possible that the receptor itself could function as a channel. Very little is known about structure–function relationships for such channels except in the case of bacteriorhodopsin[46] and the acetylcholine receptor[47]. For both these proteins it seems that multiple transmembrane segments formed from either a single polypeptide in the case of bacteriorhodopsin or from multiple subunits in the case of the acetylcholine receptor contribute to channel function. Inspection of the putative EGF receptor transmembrane sequence suggests that, even if ligand-induced aggregation brought several transmembrane segments into close apposition, the sequence itself does not contain any amino acids with side chains that could be involved in ion or proton translocation.

An alternative hypothesis is that an EGF-induced conformational change in the external domain is transmitted to the cytoplasmic domain, perhaps as a result of movement of the transmembrane domain but more likely involving receptor aggregation. EGF will induce receptor clustering[48–50] and antibody cross-linking can mimic the effects of the growth factor[51,52]. Such clustering of extracellular domains would necessarily bring the corresponding cytoplasmic domains into close proximity, allowing inter-receptor interactions which might include stimulation of tyrosine kinase activity resulting in autophosphorylation. The experimental evidence cannot exclude a mechanism where a receptor molecule bearing bound ligand interacts with other polypeptides which transduce the transmembrane signal and hence stimulate kinase or other activities indirectly. However it is important to note that EGF can stimulate tyrosine kinase activity of highly purified EGF receptor (ref. 53 and Y.Y., in preparation).

Comparison of receptor gene expression patterns in normal placental tissue and the tumour cell line A431 has revealed distinct differences both at the transcriptional and at the gene structural level. We have shown that the EGF receptor is encoded by a 5.8-kb mRNA in both placental and A431 cells. We also detect a 10.5-kb mRNA which may be a transcriptional variant derived from the same gene, perhaps carrying a longer 3′-untranslated region, analogous to other genes[38,39]. Both the 5.8- and 10.5-kb mRNAs are expressed at variable but similar levels in both cells, which is remarkable because A431 cells are known to possess 10–50-fold more cell surface EGF-binding sites and associated tyrosine kinase activity than most other cell types[16,17]. The abnormality we detect instead is that A431 cells synthesize a 2.8-kb mRNA at levels 100-fold greater than that of the larger mRNA species. This mRNA encodes a 70,000-MW secreted polypeptide representing almost the entire extracellular EGF binding domain of the receptor[22]. Since this truncated receptor is secreted[22], it cannot account for the observed overexpression of EGF receptors detected by increased EGF binding capacity[1], monoclonal antibody binding[42], immunoprecipitation of tyrosine kinase activity[4,5] and receptor protein quantification as observed on SDS-polyacrylamide gel analysis of these cells[14].

Thus the important question of the mechanism for the dramatically increased EGF receptor levels in A431 cells remains unsolved. We have found that the EGF receptor gene is amplified 15–20-fold in A431 cells, yet amplification does not lead to concomitant increased synthesis of the 5.8- and 10.5-kb mRNAs. A431 cells contain two normal copies of chromosome seven and two chromosomes bearing a chromosome seven translocation[18]. Others have observed that gene amplification events are often associated with chromosomal translocations[54,55], and Shimizu and Kondo have shown that the overproduction of EGF receptor in A431 cells is genetically linked to the chromosome seven translocation (M4)[18]. We propose that the 5.8-kb and 10.5-kb mRNAs are derived from the two normal copies of chromosome seven, while the novel overexpressed 2.8-kb mRNA is derived from the amplified gene copies. Our results do not explain the link between high levels of intact receptors with chromosome 7 translocation.

Amplification of the EGF receptor gene in A431 cells could have occurred intrachromosomally or by generation of acentric extrachromosomal elements (so-called double minute chromosomes). It is possible that the sequence rearrangements we detected (A.U., in preparation) occurred during or after the translocation process and created an altered copy of the EGF receptor gene, leading to truncation and moderate overexpression, before amplification. Alternatively, sequence alterations could have occurred during gene amplification, resulting in overexpression of a single aberrant gene. Detailed analysis of the EGF receptor gene and flanking sequences from normal and A431 cells will be necessary to determine whether the occurrence of the amplified gene generates a truncated mRNA and why this mRNA is overexpressed.

It is also not clear from these results why A431 cells are uniquely unresponsive to the amounts of growth factor which are usually mitogenic for fibroblasts[19,20,56].

The finding that A431 vulval carcinoma cells produce a truncated polypeptide which is virtually identical to the external domain of the receptor is particularly intriguing in view of our earlier observation that the v-*erb-B* oncogene encodes what seems to be a truncated avian receptor polypeptide corresponding to the transmembrane and cytoplasmic domains[14]. We cannot yet exclude the presence, at a low level, in A431 cells of an mRNA which could encode such a cytoplasmic membrane-associated domain. It seems likely that the A431 2.8-kb mRNA and the secreted EGF receptor external domain are unique to

A431 cells and do not provide any clues to the neoplastic origin or character of this cell line. Since the A431 cell line—and the many variants of this cell line which must now exist (see Fig. 5)—has a multitude of defects exemplified by its 78 chromosomes[18], it is clearly best to regard this cell line with caution when exploring the mechanism of action of EGF or in characterizing changes which relate in a meaningful way to neoplasia.

The structural studies described here provide a basis from which to probe other cell lines and primary tumour tissue for alterations in the EGF receptor, its gene, or its transcription pattern.

After this manuscript was completed two publications related to the subject appeared. It was shown that A431 cells produce a 105,000-MW protein related to the external domain of the molecule[63], as previously reported by Mayes and Waterfield[22], and that amplification and altered expression of the EGF receptor gene occurs in A431 cells[64].

We thank Mark Vasser, Parkash Jhurani and Kim Dinkelspiel for synthesis of oligonucleotide primers; Jeanne Arch for manuscript preparation; and Drs Suzanne Pfeffer and S. Earp for stimulating discussions. This work was supported in part by grants from the NIH (CA 25820 to J.S.) and from the US–Israel Binational Foundation.

Conservation and change in the DNA sequences coding for alcohol dehydrogenase in sibling species of *Drosophila*

Mark Bodmer* & Michael Ashburner

Department of Genetics, University of Cambridge, Cambridge CB2 3EH, UK

The DNA sequences of the alcohol dehydrogenase (Adh) *genes of four very closely related species of* Drosophila *show that the rates of nucleotide change vary greatly in different functional domains of this gene. A phylogeny of these species based on the* Adh *sequence data is consistent with that based on polytene chromosome banding patterns.*

SPECIES of *Drosophila* are ideal for studies of DNA sequence evolution as we have very detailed knowledge of the phylogenetic relationships within many groups of the genus[1]. *Drosophila melanogaster* is an unusual member of the family Drosophilidae—it is one of a very small number of species (8 out of over 2,700) that is virtually cosmopolitan in its geographical distribution. Its closest relative, *Drosophila simulans*, is also cosmopolitan, although until recently it was rare in South-East Asia and Japan[2,3]. Recent studies of the drosophilid fauna of Africa have identified six species closely related to *D. melanogaster* and *D. simulans*[4–9]. These are *Drosophila yakuba* and *Drosophila teissieri*, widely distributed in sub-Saharan Africa; *Drosophila erecta* and *Drosophila orena*, known only from tropical West Africa; and *Drosophila mauritiana* and *Drosophila sechellia*, endemic to the islands of Mauritius and the Seychelles respectively. These eight species form the *melanogaster* species subgroup. Morphologically they are very similar, their male genitalia providing their only reliable distinguishing features. Ecologically the six Afro-tropical species may be more restricted than either *D. melanogaster* or *D. simulans*: for example *D. erecta* breeds almost exclusively on the fallen

* Present address: Celltech, 250 Bath Road, Slough SL1 4DY, Berkshire, UK.

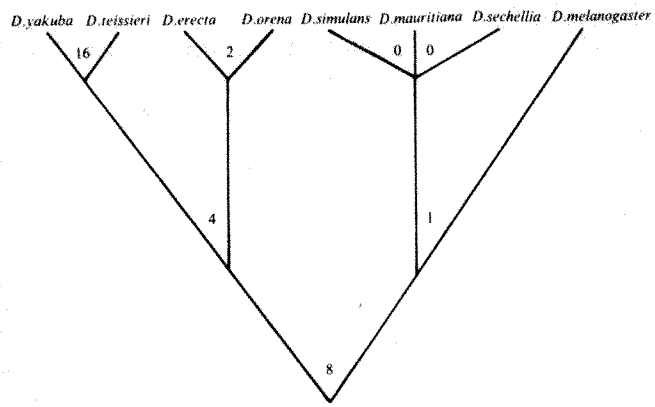

Fig. 1 The relationships among the eight species of the *D. melanogaster* species subgroup based upon their polytene chromosome banding patterns (ref. 10 and F. Lemeunier and M.A., in preparation). Within the *D. melanogaster* complex only one large inversion distinguishes the chromosomes of *melanogaster* itself from those of the other three species. The chromosomes of the members of the *yakuba* complex differ from those of the *melanogaster* complex by at least eight autosomal inversions. The numbers on the diagram indicate the minimum number of autosomal inversions that have accompanied each cladistic event.

Table 1 ADH amino acid sequence changes

	D. m (ADH-S)	*D. m* (ADH-F)	*D. sim*	*D. mau*	*D. ore*
2	Ser	Ser	Ala	Ala	Ala
28	Leu	Leu	Leu	Val	Val
51	Lys	Lys	Lys	Gln	Lys
83	Gln	Gln	Lys	Lys	Lys
85	Lys	Lys	Lys	Lys	Thr
100	His	His	His	His	Tyr
193	Lys	Thr	Lys	Lys	Lys
213	Thr	Thr	Thr	Thr	Ile
215	Pro	Pro	Pro	Pro	Ser
231	Gln	Gln	Gln	Gln	Glu
241	Gly	Gly	Gly	Ser	Gly
247	Gln	Gln	Gln	Gln	Lys
249	Thr	Thr	Thr	Thr	Ser

The predicted changes in amino acid sequence of ADH from *D. simulans* (*D. sim*), *D. mauritiana* (*D. mau*) and *D. orena* (*D. ore*) are compared with those of the ADH-S and ADH-F allozymes of *D. melanogaster* (*D. m*). The *D. melanogaster* sequences were directly determined from the proteins[21] with the exception that an extra tryptophan residue (Trp 252) was identified from the sequence of a partial cDNA clone[47]. Residues 1–33 are coded for by exon 1, 34–168 by exon 2 and 169–256 by exon 3. Residue 1 is counted as the initiating methionine. Differences from ADH-S are underlined.

fruits of the palm *Pandanus candelabrum* and *D. sechellia* on the fruits of the Rubiaceous shrub *Morinda citrifolia*[4–9].

Comparison of the polytene chromosome banding patterns of the *D. melanogaster* subgroup distinguishes two species complexes (ref. 10 and F. Lemeunier and M.A., in preparation). *D. melanogaster*, *D. simulans*, *D. mauritiana* and *D. sechellia* have similar chromosomes, only one large inversion on chromosome 3R distinguishing the chromosomes of *D. melanogaster* from those of the other species of this complex. The chromosomes of the remaining four species differ from those of the *D. melanogaster* complex by at least seven inversions. *D. yakuba*, most dissimilar from *D. melanogaster*, differs by at least 30 inversions[10]. Consideration of the inversion events required to derive the polytene chromosome banding patterns among these species gives the tree shown in Fig. 1. This hypothesis is supported by studies of hybridization within the species subgroup[11], by studies of the electrophoretic mobilities of certain enzymes[12–14], by the nature of their mitochondrial, ribosomal and satellite DNAs[15–18] and by the reaction of the species to parasitization by Cynipid wasps[19].

The *Drosophila Adh* gene

Against this background we have sequenced the genes coding for alcohol dehydrogenase (ADH; EC 1.1.1.1) from three of these species and compared them with that of *D. melanogaster* (ref. 20 and H. Haymerle and C. Benyajati, unpublished data). ADH is an abundant protein in all species of the subgroup. In *D. melanogaster* ADH is polymorphic: two electromorphs (ADH^S and ADH^F) are ubiquitous and a third ($ADH^{CH\text{-}D}$) is found in some populations. The amino acid differences between ADH^S, ADH^F and $ADH^{CH\text{-}D}$ are known, the three proteins differing in only two positions[21,22]. Kreitman[20] has sequenced the DNA of *Adh* genes from six chromosomes carrying Adh^S and five chromosomes carrying Adh^F from *D. melanogaster*. Apart from the single base pair change responsible for the lysine to threonine substitution that distinguishes ADH^S from ADH^F, these sequences differ at sites that are 'silent' with respect to the protein.

ADH activity varies during the development of *D. melanogaster*; two peaks of activity are found, the first in mature larvae and the second after eclosion of the adults[23]. The gene's transcription pattern differs between larvae and adults, although the two mRNAs encode the same protein[24]. The transcriptional organization of *Adh* in *D. melanogaster* is summarized in Fig. 2. The 'larval' and 'adult' ADH mRNAs differ in their 5′ ends. The primary adult transcript initiates 707 base pairs (bp) upstream from the larval; the removal of a 654 base intron from the primary adult transcript gives two mRNAs that differ by 50 bases in size.

Adh sequences in sibling species

Using the clones of *D. melanogaster Adh* isolated by Goldberg[25], we isolated the *Adh* genes of *D. mauritiana*, *D. simulans* and *D. orena* (see legend to Fig. 3).

The *Adh* gene sequence from these three species is compared with that of *D. melanogaster* in Fig. 3. The general structure of *Adh* is very similar, suggesting that the overall transcriptional organization is identical in the four species. The coding regions are identical in length. Table 1 summarizes the predicted amino acid changes. The amino acid sequence of the *D. simulans* ADH differs from that of *D. melanogaster* ADH^S by two residues: the N-terminal serine residue of *D. melanogaster* is replaced by an alanine residue in *D. simulans*, and the glutamine to lysine change at residue 83 accounts for the difference in electrophoretic mobility between these enzymes[26–28]. The *D. mauritiana* enzyme is predicted to differ from that of *D. melanogaster* at 5 sites and the *D. orena* enzyme at 10. Within the coding region there are 192 'effectively silent' (synonymous) sites at which a single base substitution cannot result in a coding change[20]. There are nearly 10 times as many synonymous as coding substitutions (Table 2). Overall, 20.8% of the synonymous, but only 2.2% of the non-synonymous, sites differ.

There are two coding region introns in the *Adh* gene of *D. melanogaster*, of 65 and 70 bp. The genes of the three other species have introns at identical places and of similar lengths, though in the case of *D. orena*, of quite different sequence.

Kreitman[20], in his study of 11 alleles of *D. melanogaster Adh*, found 38 polymorphisms, of which only two affected sequence length. Both of these were within the 5′ intron of the adult transcript (intron 1) and both were substitutions in Adh^F alleles that involved a partial duplication of surrounding sequences. Among our sequences, 25 of the 172 sequence variations alter length. Two of the sites of insertion within intron 1 (the 7 bp duplication at position 505 of *D. mauritiana* and the 5 bp insertion at 613 of *D. orena*) are very close to the sites of insertion in Adh^F alleles[20]: the *D. mauritiana* duplication is 1 bp 5′ to the Adh^F distal insertion and the *D. orena* insertion is 3 bp 5′ to the Adh^F proximal insertion. The longest deletion is seen in *D. orena*—this species lacks 12 bp immediately distal to the

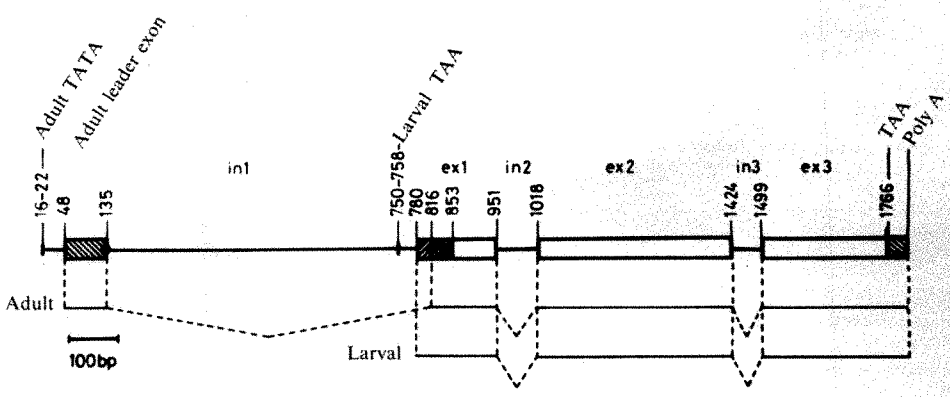

Fig. 2 The general features of the organization of the *Adh* gene of *D. melanogaster* (from refs 24 and 25). in1, in2 and in3 are the three introns and ex1, ex2 and ex3 the three coding exons. The positions of the nucleotides correspond to those of the consensus sequence shown in Fig. 3.

initiating codon. This deletion may account for the lowered levels of both ADH activity and protein in *D. orena*, which are about 30% of those of *D. melanogaster*[29].

Selective or neutral changes?

The most obvious conclusion from the data is that the rate of nucleotide substitution is higher in noncoding than in coding regions, implying selective constraints against coding region changes. Of the 768 nucleotides in the coding region, 576 (75%) could mutate to give an amino acid substitution. Between *D. melanogaster* and *D. orena*, 14.6% of the effectively silent sites have changed. We can estimate, therefore, that 84 (14.6% of 576) mutations, affecting approximately one-third of the codons, would have occurred in the coding region. Only 12 (2.2% of codons) of these have survived. This supports Kreitman's[20] conclusion that natural selection operates against coding mutations, most of which are likely to be deleterious. On the other hand the effectively silent sites show a far higher level of substitution. There are 192 sites within the coding region at which no nucleotide substitution results in an amino acid change. Forty (20.8%) of these are variable, twice the frequency of change seen in the mRNA 5′ noncoding regions.

There is significant heterogeneity in the distribution of nucleotide changes amongst the three sections of the coding region that are split by introns 2 and 3. A 3×2 contingency χ^2 test gives $\chi^2_2=9.64$; $P<0.01$. The coding region in exon 2 is the most highly conserved and that in exon 3 is the least conserved. Six of the amino acid replacements (out of a total of 12) are in the C-terminal 50 residues of the protein. It has been suggested that the coenzyme (NAD) binding sites of *D. melanogaster* ADH lies within the N-terminal 90 residues of the protein[28] and we can speculate that both this site, and the substrate binding site, lie within exon 2.

The rate of change in untranslated leader sequences is similar to that of coding DNA, and about half that seen in the intron sequences (Table 2). A similar result has been found in other studies[30,31]. This suggests that selective constraints are exerted on noncoding regions of mRNAs. They may be due to functional requirements for transcription and modification of the mRNAs, or to the demands for the interaction of other molecules with mRNA. These demands may constrain either the precise sequences of these untranslated regions or simply their secondary structure.

There is clearly a hierarchy of constraint on change in different parts of the *Adh* sequence, the percentage changes descending in the order: exon silent sites (20.8%), introns (14.1%), untranslated leader sequences (8.4%) and amino acid replacement sites (2.2%). Intron boundaries are also very highly conserved, but we cannot quantitate this as we have no rules for defining the precise limits of those sequences required for correct splicing of the primary transcript.

It is remarkable that silent sites within exons are so much more variable than the intron sequences. This unexpected complexity in the patterns of variation within the gene will be difficult to unravel until we have a better understanding of the function of intron sequences.

Evolution and phylogeny

There have been several studies of the genetic distance between members of the *D. melanogaster* species subgroup based upon the observed distribution of electrophoretic polymorphisms[12–14]. In the Hawaiian picture-winged drosophilids Carson[32] has correlated genetic distance with time, using the known age of the Hawaiian Islands. On this basis *D. melanogaster* and *D. simulans* diverged about 0.8 Myr ago, *D. simulans* and *D. mauritiana* 0.4 Myr ago and *D. melanogaster* and *D. orena* perhaps 2.0 Myr ago (assuming that the genetic distance between *D. erecta* and *D. orena* is small). However studies of electrophoretic variation within *D. melanogaster* and *D. simulans*[33–36] have shown as great a genetic distance between geographically distant populations of *D. melanogaster* as between these species. It is interesting that comparisons of the DNA sequence of *Adh* also shows a similar phenomenon, the amount of variation within *D. melanogaster* is, overall, of the same order of magnitude[20].

Table 2 Summary of *Adh* gene sequence changes

	Length (bp)	No. of changes					
		D. m	*D. sim*	*D. mau*	*D. ore*	Total	%

The numbers of changes from the consensus sequence are shown for the *Adh* genes of *D. melanogaster* (*D. m*), *D. simulans* (*D. sim*), *D. mauritiana* (*D. mau*) and *D. orena* (*D. ore*). Additions and deletions of more than one contiguous base are counted as one change.

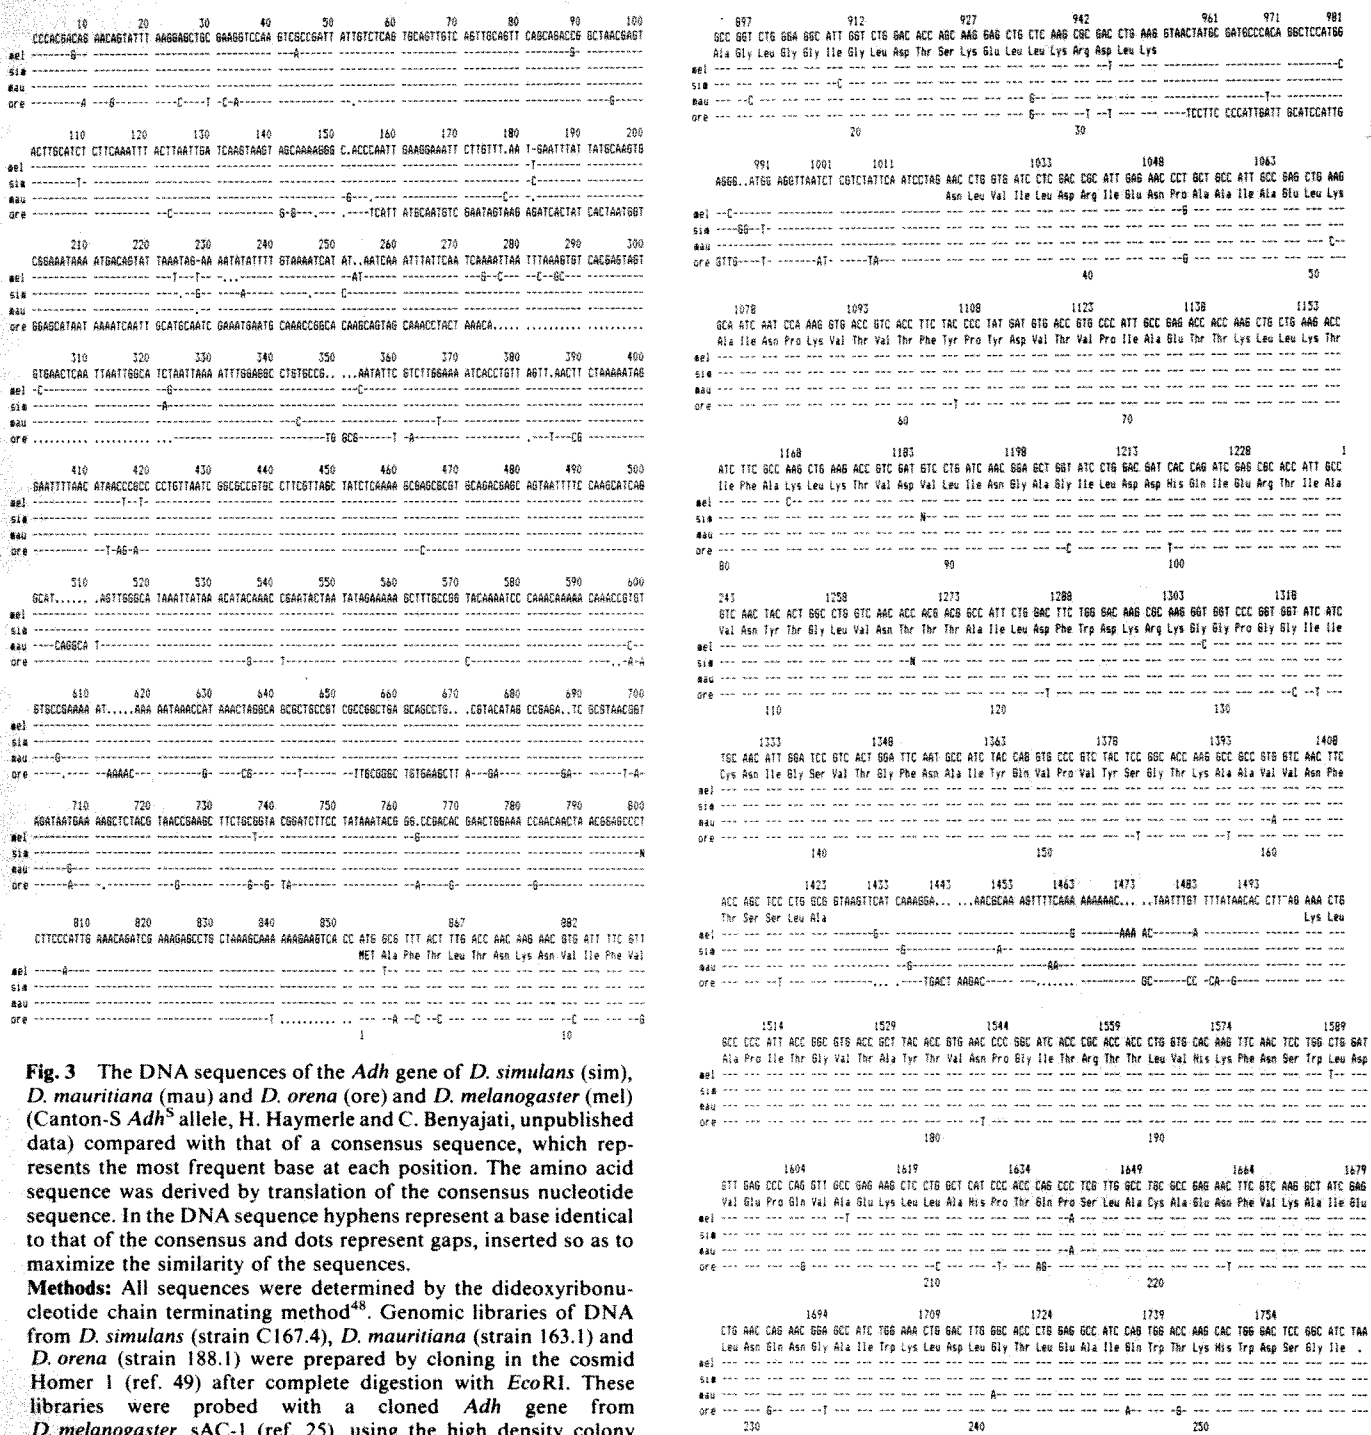

Fig. 3 The DNA sequences of the *Adh* gene of *D. simulans* (sim), *D. mauritiana* (mau) and *D. orena* (ore) and *D. melanogaster* (mel) (Canton-S Adh^S allele, H. Haymerle and C. Benyajati, unpublished data) compared with that of a consensus sequence, which represents the most frequent base at each position. The amino acid sequence was derived by translation of the consensus nucleotide sequence. In the DNA sequence hyphens represent a base identical to that of the consensus and dots represent gaps, inserted so as to maximize the similarity of the sequences.

Methods: All sequences were determined by the dideoxyribonucleotide chain terminating method[48]. Genomic libraries of DNA from *D. simulans* (strain C167.4), *D. mauritiana* (strain 163.1) and *D. orena* (strain 188.1) were prepared by cloning in the cosmid Homer 1 (ref. 49) after complete digestion with *Eco*RI. These libraries were probed with a cloned *Adh* gene from *D. melanogaster*, sAC-1 (ref. 25), using the high density colony hybridization procedure[50]. Hybridization of the *Adh* clones of these species to whole genomic DNA, digested with *Eco*RI, confirmed that the fragments cloned were of the same size as the single genomic fragments containing homology to sAC-1. The *D. simulans* sequence was obtained by sonicating the 4.79 kilobase (kb) *Eco*RI genomic fragment of this species that is homologous to sAC-1, and 'shotgun' cloning the fragments into M13mp8 (ref. 51). The *D. mauritiana* sequence was obtained in part by random shotgun clones of the 4.79 kb *Eco*RI fragment homologous to sAC-1 and in part from subclones in M13 made from *Hpa*II digestion of the *Eco*RI clone. We assumed, and then verified, that the *Hpa*II restriction sites of the 4.79 kb *Eco*RI clones of *D. melanogaster* and *D. mauritiana* are similarly distributed. The final 10 bp of *D. mauritiana* (from the *Hpa*II site at 1,756) was not sequenced. The size of the ADH polypeptide of this species, obtained by *in vitro* translation of its mRNA, is indistinguishable from those of the other species of this subgroup[29]. The *D. orena* sequence was derived from *Alu*I and *Hae*III restriction fragments of a 12 kb *Eco*RI clone (in pAT513) that included the entire *Adh* gene of this species. Subclones in M13 were identified by colony hybridization with a 2.37 kb *Sal*I–*Xba*I fragment of sAC-1.

as the difference between single *D. melanogaster* and *D. simulans* alleles.

Miyata[37] has shown that in mammals the rate of synonymous codon substitution is rather uniform, at $\sim 5.4 \times 10^{-9}$ per nucleotide per year. If we use this value to estimate the time of divergence of the species of the *D. melanogaster* species subgroup then we obtain times greater than those suggested by the electrophoretic data: 3.9 Myr for *D. melanogaster–D. simulans*, 2.9 Myr for *D. simulans–D. mauritiana* and 13 Myr for *D. melanogaster–D. orena*.

These estimates will be biased by the longer generation time of mammals than *Drosophila*. Moreover, we cannot assume that synonymous substitutions are neutral. Codon usage in *Adh* is nonrandom. This is most clearly seen in a deficit in codons ending in A and T, and a corresponding excess of G and C—a pattern which is also seen in other sequenced *Drosophila* genes

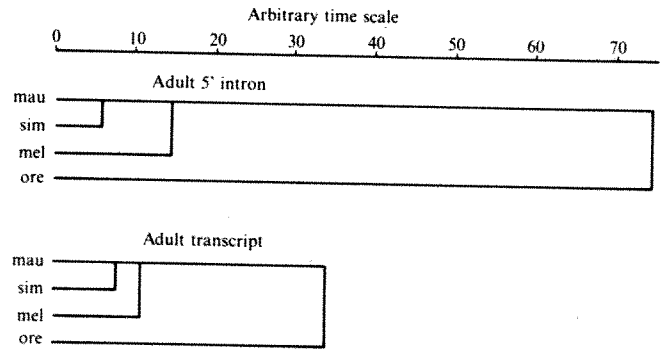

Fig. 4 Trees of the phylogenetic relationships of *D. melanogaster*, *D. simulans*, *D. mauritiana* and *D. orena* generated by M. J. Bishop's DNAPEQ computer program. The model used by this program makes two assumptions: (1) The genome is under a constant mutational threat, damage being repaired by proofreading functions of DNA polymerases. The model then assumes a constant failure rate of repair at any individual site (u, which is independent of any previous events at that site) and calculates a probability ($1-e^{-ut}$) that failure will occur over time t. This is termed the exponential failure law. (2) There is an equiprobable chance of replacement by A, C, T or G (allowing for a base to be replaced by itself). The calculation requires that the sequences be aligned for maximum homology. It regards all changes as single base substitutions, and all additions, deletions or replacements are removed. The upper tree is for sequence comparisons of intron 1, the lower tree compares the adult transcripts from their initiation sites with the termination codons. The time scale is arbitrary and could only be transformed to real time were the rates of mutation (u) known.

(M.A., unpublished data). Nonrandom codon usage is well known in other species (see, for example, ref. 38) and is especially marked in genes whose products are, like ADH in *Drosophila*, abundant[39,40]. In *Drosophila* the pattern of nonrandomness differs from that of many other eukaryotes due to there being no strong deficit of C·G doublets (M.A., unpublished data), correlating with the very low amount of the modified base 5-methylcytosine in this species[41–43]. The frequencies of transition and transversion changes among the four sequences are heavily biased towards transitions (Table 3). This is not surprising for the coding regions, as no pyrimidine, and only two purine transitions cause amino acid replacements, but it was unexpected for noncoding regions, which show a 0.75 ratio of transitions : transversions rather than the expected 0.5. In the coding region there is an excess of pyrimidine transitions: 65% of the third positions are pyrimidine, but 82% of the mutations are pyrimidine transitions.

Our data clearly confirm the relationships between the four species of the *D. melanogaster* species subgroup shown in Fig. 2. The sequence of the *Adh* gene of *D. simulans* is closer to that of Adh^S of *D. melanogaster* than to Adh^F. Kreitman's comparison of Adh^S and Adh^F alleles shows 17 sites at which a consensus Adh^S sequence differs from a consensus Adh^F sequence. *D. simulans Adh* resembles Adh^S at 14 of these sites (including Lys 193) and resembles Adh^F at the other three sites (which are not clustered). As Adh^F alleles are relatively rare in the more tropical populations of *D. melanogaster*[44,45], these facts point to Adh^F as being a more recent allele than Adh^S.

Numerical methods of constructing phylogenies have been developed which allow a probabilistic assessment of the relationships among a group of species based upon a defined subset of their attributes[46]. Recently these models have been adapted to make use of nucleotide sequence data (M.J. Bishop & A. E. Friday, personal communication) and a pairwise method of phylogeny analysis has been applied to these data from the *D. melanogaster* species subgroup. We used a program (DNAPEQ) that evaluates a maximum likelihood estimate of divergence times for pairs of DNA sequences. This program uses an exponential failure model of DNA copying error, assuming an equiprobable replacement at a site by any of the four bases. DNAPEQ calculates a matrix of pairwise divergence times (on an arbitrary time scale) and these are then used to construct a tree which best fits the pairwise comparisons. Two subsets of the sequence data for the four species were analysed: one was the adult transcript, from its initiation site to the termination codon, and the other was intron 1. The two trees generated are shown in Fig. 4. They are topologically identical, although the estimates of relative divergence times differ. The tree based on the adult transcript sequence places *D. orena* half the distance from the other species as that based on intron 1. This, of course, is entirely consistent with the different levels of variation seen in these regions of nucleotide sequence. Thus, using independently defined criteria for the construction of cladograms based upon DNA sequence comparisons, the phylogenetic relationships seen in all previous studies are fully confirmed.

Table 3 *Adh* gene transitions and transversions

	Coding	Noncoding
Transitions (t)		
C↔T	24	18
G↔A	5	15
Sum	29	33
Transversions (v)		
T↔G	4	8
T↔A	2	12
C↔A	9	11
C↔G	6	13
Sum	21	44
Ratio (t/v)	1.38	0.75

The numbers are the sums over the four species of the *D. melanogaster* subgroup of single base changes from the consensus sequence shown in Fig. 3.

This work was supported by a MRC Studentship to M.B. and by grants from the MRC to M.A. and to M.A. and R. Jackson. We thank H. Haymerle and C. Benyajati for the sequence of the *D. melanogaster Adh* gene, D. Goldberg for the original clones of *D. melanogaster Adh*, R. Staden and M. Bishop for computer programs, M. Kreitman for a copy of his manuscript prior to publication, and H. Haymerle, R. Jackson, R. Karp, W. Chia, A. Jeffreys, B. Barrell, M. de Bruijn, W. Bodmer, and A. Friday for their help.

LETTERS TO NATURE

The ultraluminous interacting galaxy NGC6240

G. S. Wright, R. D. Joseph & W. P. S. Meikle

Blackett Laboratory, Imperial College, London SW7 2BZ, UK

In the course of checking preliminary lists of IRAS (Infrared Astronomical Satellite) sources to see whether any of the interacting galaxies that we have been studying[1] were included, we discovered that the position of the IRAS source 1650+024PO4 (ref. 2) is within a few arc seconds of one of our programme interacting galaxies, NGC6240. Examination of the Palomar sky survey prints shows that NGC6240 is the only non-stellar object within the 1 arc min IRAS error box for this source. Photometry at 10 and 20 μm from the United Kingdom IR Telescope (UKIRT) confirms that this galaxy is among the most luminous IR galaxies yet discovered. An interaction-induced burst of star formation is the most likely source of the strong IR emission.

Photometry of NGC6240 using UKIRT was obtained on 29 February 1984. We first found the peak in the signal from NGC6240 at K (2.2 μm), and we used this position for the longer wavelength observations. This position coincides within our measurement errors of ~2 arc s, with the optical and radio positions discussed below. Our photometric results, obtained in a 4 arc s aperture, are shown in Fig. 1, together with the published preliminary IRAS data, and available optical and radio data. This reveals that the IRAS source is indeed NGC6240.

The nuclear 10-μm luminosity of NGC 6240, inferred from our UKIRT photometry in a 4 arc s aperture, is $1.2\times10^{10}\ L_{\odot}$, based on the measured redshift[3] (7,597 km s^{-1}) and a Hubble constant H_0 of 50 km s^{-1} Mpc^{-1}. Integration of the spectrum shown in Fig. 1 yields a bolometric luminosity (L_{bol}) of $2.4\times10^{12}\ L_{\odot}$. Most of this energy is emitted in the IR, with the optical and radio emission contributing only ~10% of the total. This interacting galaxy therefore has an IR luminosity 60 times larger than the archetypal starburst galaxies M82 and NGC253 (ref. 4), for which $L_{bol}\sim4\times10^{10}\ L_{\odot}$. Its IR luminosity is an order of magnitude larger than that of the Seyfert galaxy NGC1068 (ref. 5), and comparable with that of Mkn 231 (ref. 6), the most luminous IR galaxy known.

The IR luminosity is most easily understood as arising from a massive burst of star formation, in which the radiation from young, early-type stars is thermalized by dust, and re-radiated in the IR. The quasi-thermal IR spectrum, peaking at ~100 μm, is typical of that observed in known starburst galaxies. Comparing our 10- and 20-μm fluxes in a 4 arc s aperture with the IRAS photometry at 12.5 and 25 μm in a much larger aperture, suggests that about half of the IR emission comes from a region outside the central 4 arc s. The spatial extent of this emission rules out the possibility that the dust is heated by a single compact object in the nucleus, as has been suggested for some Seyfert galaxies.

However, NGC6240 is clearly not just another starburst galaxy. It is at least an order of magnitude more luminous than typical starburst galaxies, and the recent star formation appears to be extended over an enormous region in excess of 3 kpc, significantly larger than is generally found for starburst galaxies.

A comprehensive picture of the nature of NGC6240 can be obtained using available optical and radio studies. Photographs presented by Fosbury and Wall[7] reveal that it is an extremely chaotic interacting galaxy, with a prominent dust lane and three long plumes extending from the central region. Charge-coupled device (CCD) images obtained by Fried and Schulz[8] show two distinct nuclei separated by ~2 arc s. The spectra of Fosbury and Wall, and Fried and Schulz, show intense optical emission lines arising from a region extending over at least 10 arc s. These authors have used the optical emission line intensities to distinguish between different excitation mechanisms (see ref. 9), and they find that the optical emission is characteristic of shock excitation.

NGC6240 is also a very bright radio source with a luminosity at 1,413 MHz (ref. 10) of 4.2×10^{22} W Hz^{-1} Sr^{-1}. The Very Large Array (VLA) maps of Condon *et al.*[10] show that the radio emission is coextensive with the region of intense optical line emission. The two nuclei are also clearly resolved at 4,885 MHz. Other bright radio galaxies in the Condon *et al.* sample have an IR (10 μm)-to-radio (1,445 MHz) flux density ratio of ~4. They suggest that this relation can be understood in terms of a starburst model, with the radio emission arising from supernova remnants associated with the starburst. Comparing our 10-μm flux density with the radio flux density for NGC6240 measured by Condon *et al.* for the central 5 arc s gives a ratio of 0.5. Evidently a simple starburst model is inadequate for NGC6240, and an additional energy source for the radio emission is required. Fosbury and Wall[7] suggest that the strong radio emission in NGC6240 is due to relativistic particles accelerated in the shock fronts. This interpretation appears to be more

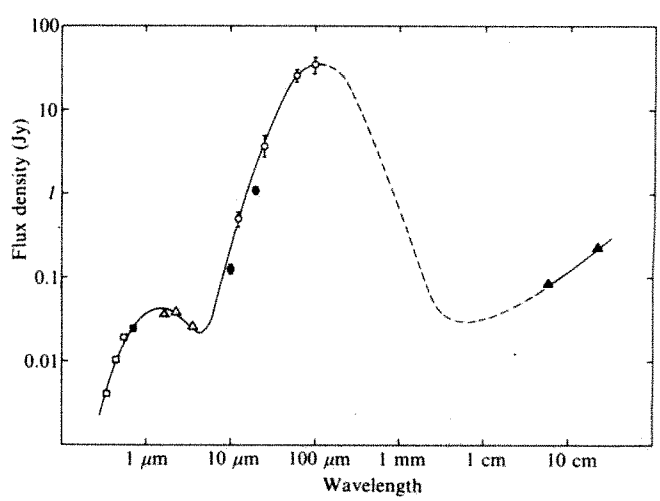

Fig. 1 Continuum spectrum of NGC6240. Data from: ●, this paper; ○, ref. 2; □, ref. 7; ■, ref. 8; △, ref. 15 and ▲, ref. 10. The dashed interpolation is a Rayleigh–Jeans Spectrum with emissivity proportional to λ^{-1} joined smoothly to the data at longer and shorter wavelengths.

consistent with the small IR-to-radio flux density ratio we find for this galaxy.

The physical picture of NGC6240 which emerges from all of these studies is that of an interaction between two gas-rich galaxies. If the impact parameter is small enough, dynamical friction will be adequate to dissipate the orbital kinetic energy and a merger of the two galaxies will ensue, as discussed by Toomre[11] and others. Such interactions produce large non-circular gas motions and infall of material as the colliding galactic nuclei spiral towards each other. The resulting shocks in this material can trigger a massive burst of star formation. NGC6240 seems to be a clear example of this process. The two nuclei, and the strong evidence of shock excitation on large scales, support this model. Furthermore, the thermal character of the IR spectrum, the very large IR luminosity, the spatial extent of the IR emission, and the corresponding spatial extent of the ionized gas are strong circumstantial evidence of a massive burst of star formation, fuelled and triggered by the interaction.

These physical processes and events in NGC6240 are similar to those which we[1] and others (see, for example, ref. 12) are finding in studies of interacting galaxies. NGC6240 is remarkable because it is such a spectacular and energetic example.

There is mounting evidence that interactions are associated with other types of active galactic nuclei[13,14]. The properties of NGC6240 outlined above demonstrate that this association has physical plausibility. In particular, interaction-induced starbursts are capable of supplying luminosities at least as large as those characteristic of all but the most luminous active galaxies.

We thank Norna Robertson and James Graham for stimulating discussions on the physics of interacting galaxies and Dave King for assistance in measuring the source position. G.S.W. is an SERC-supported research student.

Solid white dwarfs as Type I supernova progenitors

Jordi Isern*, Javier Labay* & Ramón Canal†

* Departamento de Física de la Tierra y del Cosmos, Universidad de Barcelona, and Grup d'Astrofísica de la SCF (IEC), Barcelona-28, Spain
† Astronomy and Astrophysics Center, University of Chicago, Illinois 60637, USA

Mass-accreting white dwarfs in close binary systems are generally thought to be Type I supernova (SN I) progenitors. Low-mass ($M_{tot} \lesssim 5\,M_\odot$) binary X-ray sources (also known as Type II sources) equally appear to be the descendants of cataclysmic variables (CV) and thus to have been produced by the collapse of a mass-accreting white dwarf. We point out here that a single process, thermonuclear ignition inside a partially solid, carbon–oxygen white dwarf, may account for the full range of phenomena: from mildly or non-explosive collapses leaving a condensed remnant up to 'slow' to 'fast' SN I outbursts with total disruption of the parent star.

Type I supernovae (SN I) display a high degree of photometric and spectroscopic homogeneity[1]. The radioactive decay model[2,3] successfully accounts for their characteristic light curves. Between 0.2 and 1.0 $M_\odot$ of ^{56}Ni should be synthesized in each explosion; the exact values depend on the adopted value of the Hubble constant: $H_0 \sim 100\ \mathrm{km\ s^{-1}\ Mpc^{-1}}$ would correspond to the lowest masses and would imply a condensed remnant being left by the explosion[5]. Despite the aforementioned homogeneity, some range of variation is detected among the outbursts[6]: 'slow' supernovae show higher peak luminosities, higher velocities in their ejecta and slower declines in their light curves; 'fast' supernovae are dimmer, the velocities of the expanding material are lower and the light curve's decay is faster. Those characteristics are well fitted by Arnett's analytical models[7]. An 'effective diffusion time' τ_m is defined:

$$\tau_m \propto (M_{ej}^3 / M_{Ni})^{1/4}$$

where M_{ej} and M_{Ni} are, respectively, the masses of the ejecta and of the synthesized ^{56}Ni. Larger τ_m values mean slower light curve declines. The expansion velocities and the peak luminosities are also related to the above quantities by

$$v_{ej} \propto (M_{Ni}/M_{ej})^{1/2}$$

and

$$L_{peak} \propto M_{Ni}$$

The most fashionable model for explaining the outbursts involves central deflagration of a white dwarf in a close binary system, leaving no remnant[8], but this model implies a 'unique' configuration and does not allow for variation (M_{ej} coincides with M_{tot} and the latter is roughly the Chandrasekhar's mass). Different explosion mechanisms (helium detonation, helium–carbon detonation, and so on) may then be invoked, but their predictions contradict the observations, as almost no intermediate mass elements are ejected in those models. A natural way for fitting the light curves is, however, to assume that M_{ej} is a variable fraction of M_{tot}. Other types of observations, as positron events at the galactic centre[9,10], also suggest thermonuclear explosion with relatively small amounts of ejecta[11].

Type II galactic X-ray sources (comprising globular cluster sources, galactic bulge sources, Sco X-1 type sources, and X-ray bursters) share the common characteristic of involving a neutron star with a low-mass ($M \leqslant 1\ M_\odot$) companion. While the capture mechanism might be a valid explanation for the globular cluster sources, it cannot explain the other kind of sources. Besides, the distribution of X-ray galactic bulge sources and that of the novae in M31 show a remarkable coincidence[12]. Collapse of a white dwarf in a cataclysmic variable is the most likely formation mechanism[13].

We thus have a situation which strongly suggests that mass accreting white dwarfs in close binary systems may at some point collapse and/or explode leaving condensed remnants of various masses: from practically the same mass as the collapsing white dwarf up to zero mass in the case of complete disruption. In contrast, there is almost no model which predicts such a continuous range of behaviour.

The effects of solidification in cooling carbon–oxygen white dwarfs have been pointed out[14]. One possibility is that carbon/oxygen separation happens at phase transition: oxygen 'snow' falling to the centre and carbon being rejected to the outer layers. The likely outcomes[15] are either collapse initiated by the electron captures on oxygen at the centre or off-centre carbon ignition. With the lack of a detailed numerical simulation of the liquid/solid phase transition, we consider other alternatives, such as 'percolation' in the solid phase[16]: the free energy is lower when the carbon ions imbedded in an oxygen lattice are surrounded by oxygen ions. So, if carbon were even only slightly less abundant than oxygen at the end of the helium burning (as the recent revision of the $^{12}C(\alpha,\gamma)^{16}O$ rate suggests[17]), the relevant rate for the ignition would be that of $^{12}C + {}^{16}O$ instead of $^{12}C + {}^{12}C$. Central ignition would occur when the central density $\rho_C \sim 10^{10}\ \mathrm{g\ cm^{-3}}$ and would also lead to

collapse. But even if carbon were more abundant than oxygen and/or no separation mechanism were operating solidification would still ensure at least partial collapse. This is because when thermonuclear ignition happens in the middle of a solid, the burning propagates by conduction (the successively melted layers only afterwards become convective). The characteristic speeds are between 10^{-4} and 10^{-5} times the local speed of sound[18]. Taking into account the new corrections to the electron screening factors[19], the ignition density of the reaction $^{12}C+^{12}C$ becomes $\rho_c \sim 3.5\times10^9$ g cm^{-3}. For instance, assuming the interior to be solid from the centre out to a radius 5×10^7 cm (about half the stellar radius), it takes ~500 s for the conductive burning front to reach the edge of the solid core (in contrast with ~1 s if we had assumed a convectively-driven front, or ~0.1 s for a detonation wave). Even at those relatively low ignition densities, the electron captures on the matter in nuclear statistical equilibrium (NSE)[20] are fast enough to remove pressure efficiently and start the collapse: $\tau_e = = Y_e/\dot{Y}_e \leqslant 5$ s (where Y_e is the electron mole number). When the burning front reaches the fluid layers, it changes into a convectively-driven front and accelerates.

Calculations were performed assuming central ignition in a white dwarf with a central density of 3×10^9 g cm^{-3}, with a solid core of one-tenth of the total mass, composed of a mixture of equal parts of carbon and oxygen. While the burning propagates through the solid core at a velocity of 2 km s^{-1} hydrostatic equilibrium was assumed. When the burning front reaches the solid/liquid transition, the material between that point and the layer corresponding to 1 $M_\odot$ was instantaneously incinerated. Then the hydrodynamical behaviour was followed with an explicit numerical code[21].

Our results are preliminary because we have extrapolated the approximations used for the matter in NSE to higher densities and lower Y_e than prescribed, and the hydrostatic/hydrodynamic transition should be treated more carefully. In the same way, burning propagation in the solid, as well as in the fluid, layers needs a more detailed treatment. Keeping these restrictions in mind, we conclude that the liquid layers are ejected and the solid/fluid transition sets a lower limit to the mass of the bounded remnant. Due to the low densities of those layers ($\rho \leqslant 2.35\times10^9$ g cm^{-3}) the neutron excess of the ejected matter is not too high ($\langle\eta\rangle \sim 3\times10^{-3}$).

Thus, the mere solidification of the star's interior appears to determine the implosion of the frozen layers on carbon ignition. The burning front, when reaching the still fluid layers mimics an off-centre ignition. A single parameter (the size of the solid core, resulting from the interplay between the cooling time before mass transfer and the heating effects of the accretion process[22]) determines the amount of matter ejected. So, the whole range from mildly explosive collapse (leading to the formation of Type II X-ray sources) to 'fast' and 'slow' SN I might be covered by a single mechanism based on a well understood physical process.

Topography of the shield volcano, Olympus Mons on Mars

S. S. C. Wu, P. A. Garcia, R. Jordan, F. J. Schafer & B. A. Skiff

United States Geological Survey, 2255 North Gemini Drive, Flagstaff, Arizona 86001, USA

Olympus Mons, one of the largest known shield volcanoes in the Solar System, covers an area of $>3.2\times10^5$ km^2 and has a diameter of >600 km, excluding its vast aureole deposits. The structure is five times larger than the largest shield volcano on the Earth. It is situated on the north-west flank of the Tharsis volcanic region, a broad topographic rise on the martian surface. The volcano has three physical subdivisions: the summit caldera, the terraced upper flanks, and the lower flanks, which terminate in a scarp 2–10 km high that nearly surrounds the structure. A large block of images of the Tharsis region, including Olympus Mons, was obtained by the Viking mission[1]. Here we present a topographic map of Olympus Mons, compiled using various combinations of stereo pairs of these images, together with stereoscopic perspective views generated by image processing techniques.

The contour map of Olympus Mons was compiled at a scale of 1:1,000,000 with a contour interval of 200 m, using 91 stereoscopic models of Viking Orbiter photographs[2]. Special photogrammetric techniques were used for this compilation. These techniques had been developed to use the Viking Orbiter photographs, which have extremely narrow field-of-view[3], for the systematic mapping of Mars. Three hundred and sixteen control points were produced from a block of 103 photographs using analytical aerotriangulation methods. Digital elevation data were collected from stereo models on the analytical plotter at the time of map compilation. Using techniques of digital image processing[4] shown in Fig. 2, perspective stereoscopic views were made at various vertical viewing angles from different desired azimuths. The summit caldera and the terraced upper flank are viewed monoscopically from the east and the west in Fig. 2*a* and *b*, respectively; the scarps of the lower flanks are viewed stereoscopically from the north and the south-east in Fig. 2*c* and *d*.

Previous estimates of the height of Olympus Mons ranged from 17 to 23 km above the surrounding area[5–12]. A height of 27 km above the Mars topographic datum[13] is shown on the US Geological Survey 1:25 million scale, global topographic map of Mars[14], which was compiled by synthesizing remotely-sensed data from the Mariner 9 Mars mission and Earth-based radar observations[15–16]. The newly compiled topographic map (Fig. 1), shows the elevation of Olympus Mons to be 26,400 m above the Mars datum. The volume determination of Olympus Mons calculated for individual segments bounded by contour lines on Fig. 1 is given in Table 1.

Olympus Mons has the general form and slope of a classic terrestrial basaltic shield volcano[8,17,18]. Major topographic features include a complex caldera at the summit that is ~80 km across, upper flanks that form a concentric pattern of terraced terrain, and a steep basal scarp. The summit caldera is composed of at least five coalesced collapse craters[19]. Concentric terraces on the upper flanks are prominent on the east, south-east, west, and south-west sides[20]. Typically, the terraces are spaced 15–20 km apart. The unique, nearly continuous, basal scarp rises more than 10 km above the basal plains on the north and north-west, (Fig. 1); on the south-east, the scarp rises 4–5 km

Table 1 Volume determination of Olympus Mons

	Elevation (km)	Volume of segment	Accumulated ($\times 10^6$ km^3)	Elevation (km)	Volume of segment	Accumulated ($\times 10^6$ km^3)	Elevation (km)	Volume of segment	Accumulated ($\times 10^6$ km^3)
Above	26	0.0004	0.0004	17	0.073	0.336	9	0.223	1.553
	25	0.006	0.007	16	0.088	0.424	8	9.236	1.789
	24	0.013	0.020	15	0.103	0.527	7	0.247	2.036
	23	0.022	0.042	14	0.120	0.647	6	0.262	2.298
	22	0.029	0.071	13	0.140	0.787	5	0.296	2.594
	21	0.035	0.106	12	0.158	0.945	4	0.365	2.959
	20	0.043	0.149	11	0.180	1.125	3	0.436	3.395
	19	0.052	0.201	10	0.205	1.330	2	0.467	3.862
	18	0.061	0.263						

Volumes were calculated, using a planimeter, for individual segments bounded by contour lines on the map (Fig. 1). The third column lists cumulative volumes, measured downward from the top in increments of 1 km. Blasius[7,8] reported a total volume of 2.7×10^6 km^3 for Olympus Mons and Bealty[25] reported a volume of $3–4 \times 10^6$ km^3. From the new map (Fig. 1) we calculate a total volume of 2.594×10^6 km^3 for the part of the volcano above the 5-km elevation. Assuming a density of 3.0 g cm^{-3} (ref. 26), we estimate the topographic mass of Olympus Mons to be 7.782×10^{18} kg above the 5-km elevation. If estimated volumes between elevations of 2 and 5 km are added to this calculation, the total volume above the 2-km contour is 3.862×10^6 km^3. This, in turn, gives a total mass of 11.586×10^{18} kg above the 2-km elevation.

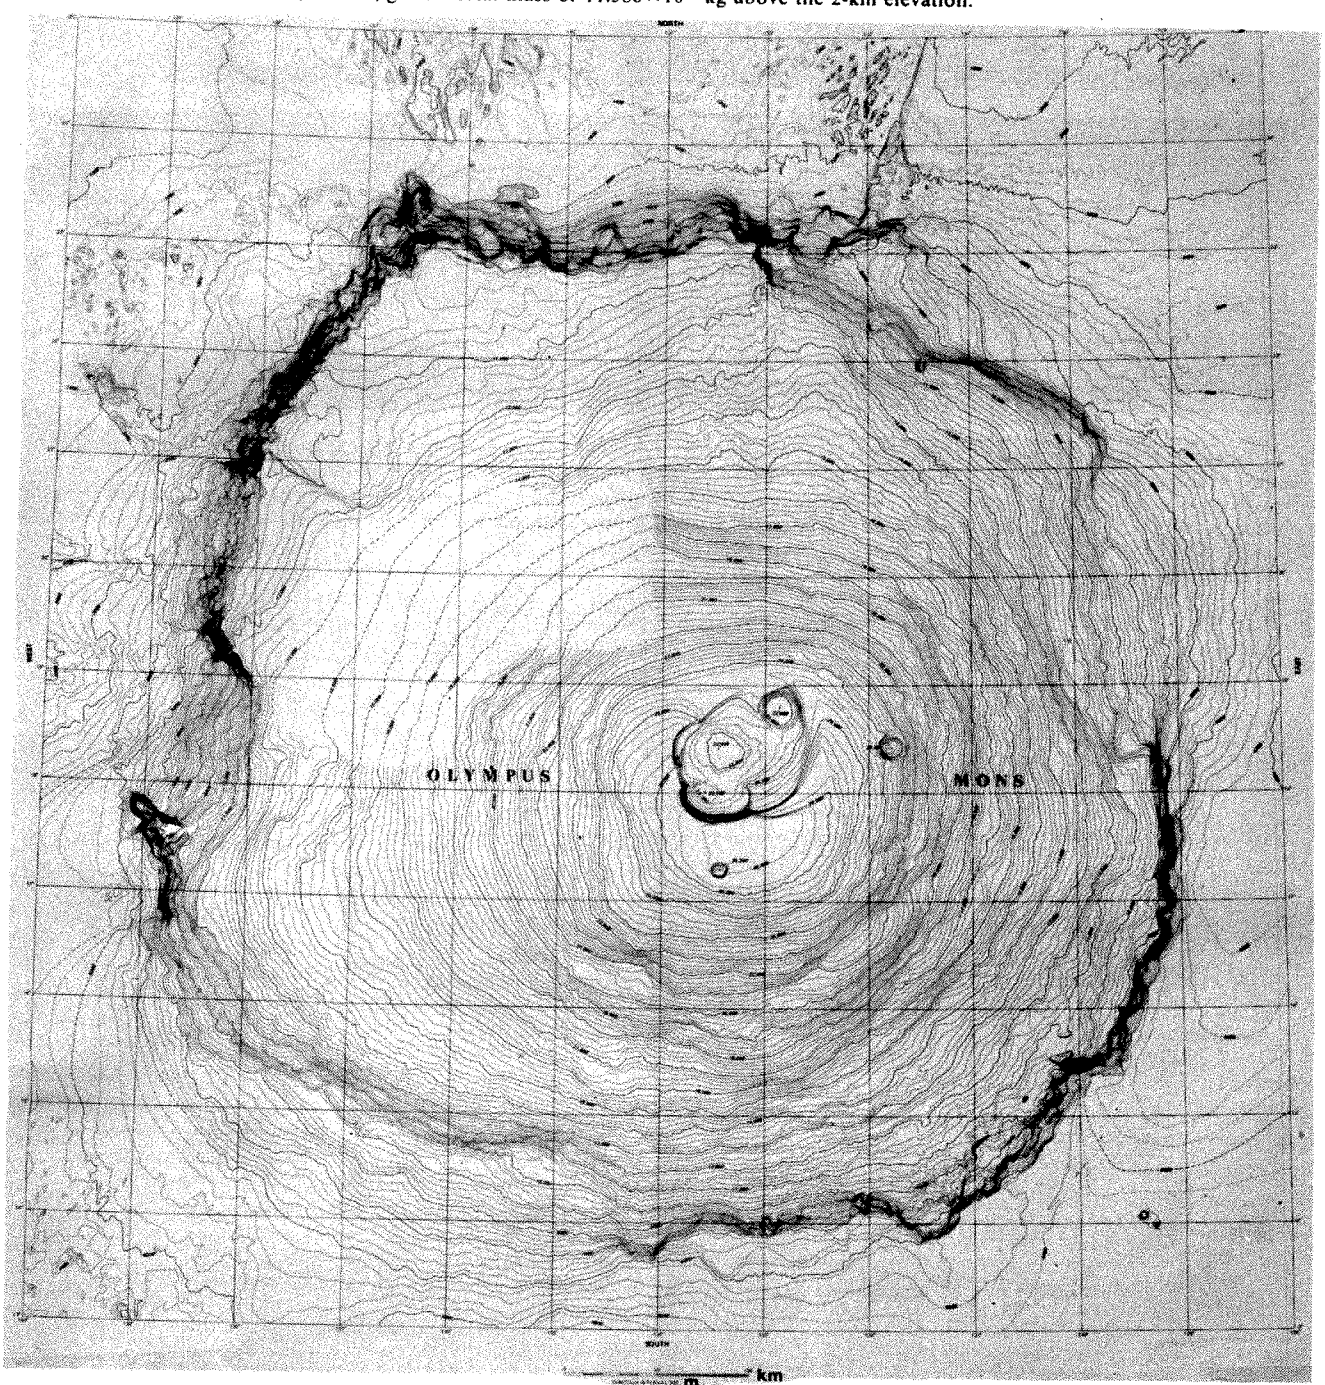

Fig. 1 Topographic map of Olympus Mons. Scale of the map, 1:1,000,000; contour interval, 200 m. Contours and elevations are in metres and are referred to the Mars topographic datum. A transverse Mercator projection was used with the central meridian placed at 134 °W long

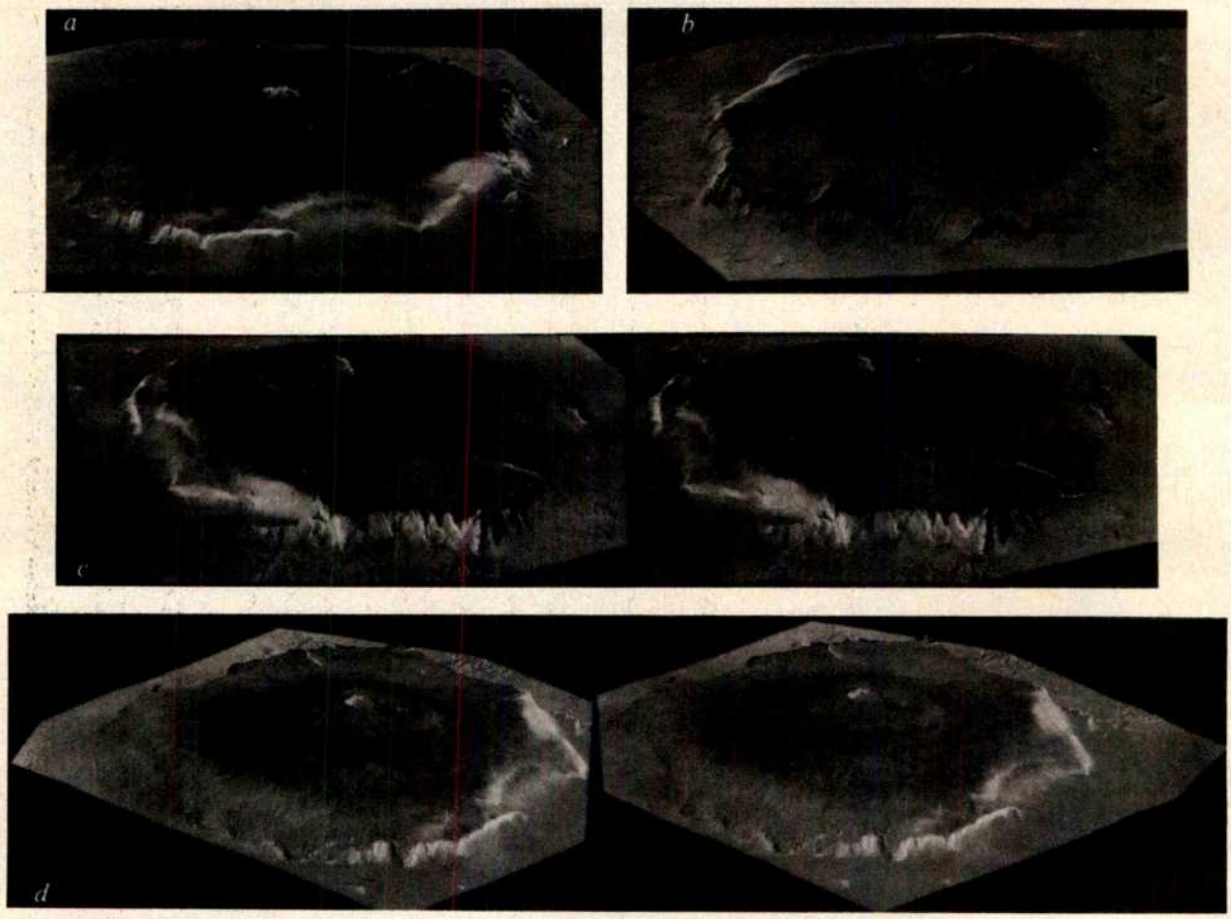

Fig. 2 Perspective views of Olympus Mons. Pictures were generated by digital image processing, from Viking Orbiter photograph646A28. Projection is controlled by digital elevation data collected at the time of the map compilation (Fig. 1). Viewing angle is 25° from the horizon. Vertical exaggeration, ×5. *a*, *b*, Monoscopic views from due east and due west; *c* and *d* are stereoscopic views from due north and from the south-east, respectively. Both stereo pairs have 5° separation in azimuth between the left and the right pictures. A stereoscope may be used for stereoscopic viewing.

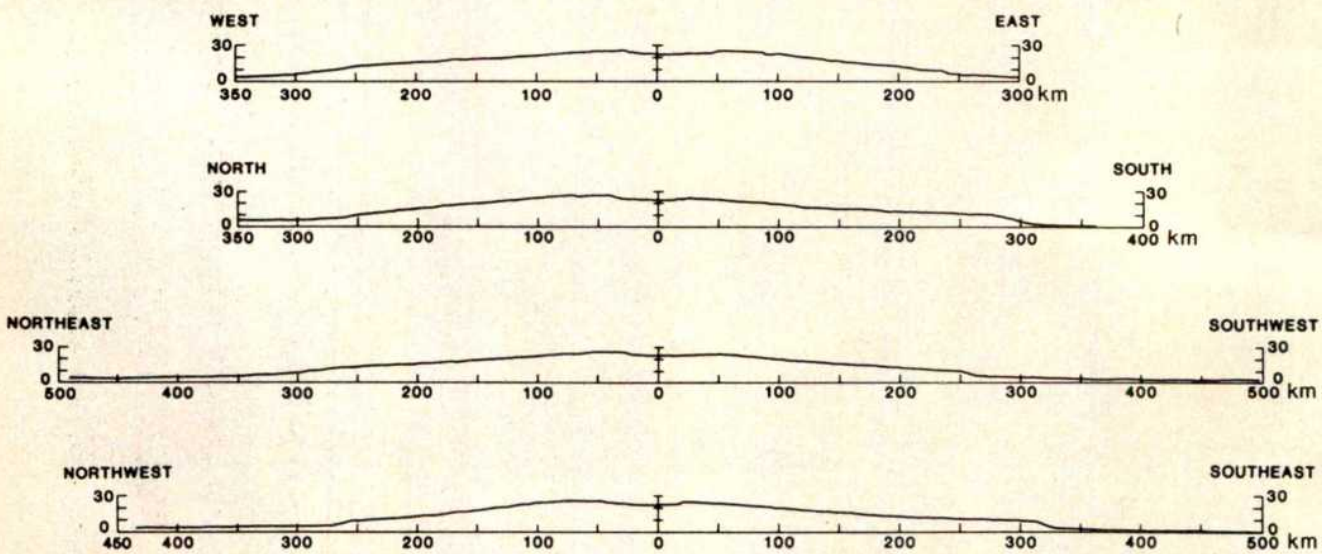

Fig. 3 Profiles measured from the topographic map (Fig. 1) of Olympus Mons. All are drawn so that they pass through the approximate centre of the summit caldera at 18.4° N lat. and 133.45° W long.

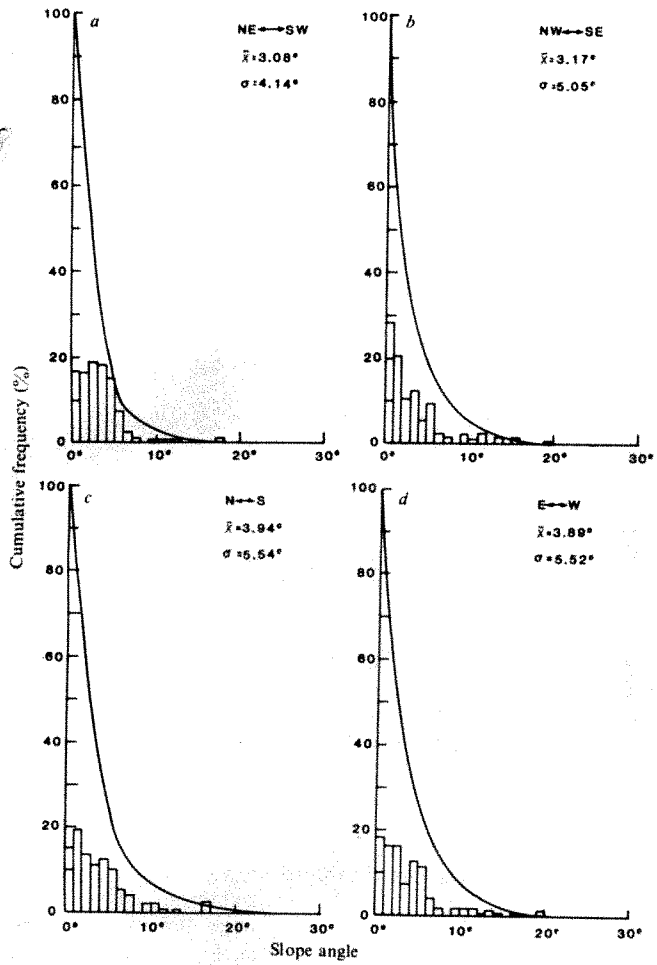

Fig. 4 Slope–frequency distributions of Olympus Mons flanks. Bars represent percentage of samples, by 1° increments of slope angle. Curved lines indicate cumulative frequency of slope angle. The quantity x is the mean absolute slope and σ is the algebraic standard distribution of the slope. *a–d*, Slopes measured along NE–SW, NW–SE, N–S and E–W directions respectively. The slope base is 5 km. These profiles, which were derived using a method of terrain analysis employing slope–frequency distributions[23,24], show the mean absolute slopes measured along the NE–SW, NW–SE, N–S and E–W directions, to be 3.08°, 3.17°, 3.94° and 3.89°, respectively. The algebraic standard slopes are 4.14°, 5.05°, 5.54° and 5.52°. Although the flank surface appears slightly smoother along its NE–SW direction, the surface of Olympus Mons shield is generally rough.

above the plains. Beyond the scarp, curvilinear troughs and ridges form a grooved terrain, the aureole deposits, which surround Olympus Mons. These deposits are some of the most puzzling features of the Olympus Mons region[1,21].

Figure 3 shows profiles measured from the map along the east–west, north–south, north-east–south-west and south-east–north-west directions. Slopes are divided, by elevation, into three groups. Within the 2–7-km interval, slopes of 2°–3° prevail; slopes of 8°–24°, between 7 and 16 km, are steeper mainly because there are several steep scarps within this elevation range; upper slopes, from 13 km to the outside rim of the caldera at 24 km (refs 2,22), measure 2.5°–6.5°.

This study was performed under NASA contracts W-14585 and L-9718.

Can X-ray diffraction distinguish between protium and deuterium atoms?

Paul Seiler, Bruno Martinoni & Jack D. Dunitz

Organic Chemistry Laboratory, Swiss Federal Institute of Technology, ETH-Zentrum, CH-8092 Zürich, Switzerland

Isotopes are not normally considered to be distinguishable by X-ray crystal structure analysis. There is, of course, no problem as far as neutron diffraction is concerned, as neutron scattering amplitudes vary markedly and irregularly from one nuclide to another[1]. In particular, the neutron scattering amplitudes of protium and deuterium have opposite signs so that these two isotopes are especially easily identified. Indeed, in a key experiment nearly 20 yr ago, this difference was used together with the anomalous neutron scattering of ^{6}Li to establish the absolute configuration of an enzymatically formed α-monodeuterioglycolic acid[2]. We discuss here the possibility of distinguishing deuterium from protium by X-ray diffraction on the basis of the difference in the vibrational behaviour of the two isotopic species.

Least-squares analysis of sufficiently accurate and extensive diffraction data provides information not only about the atomic positions but also about the vibrational behaviour. This information is usually expressed as the components of a tensor $\mathbf{U}_i$ for each atom, whereby the product $\mathbf{l}^T\mathbf{U}_i\mathbf{l}$ is the mean-square vibrational amplitude of the atom i about its equilibrium position in the direction of the unit vector $\mathbf{l}$ (ref. 3). For light X-ray scatterers, such as hydrogen atoms, the tensors $\mathbf{U}_i$ are usually contracted into scalars U_i (isotropic vibrational parameters) which represent the spherically-averaged motion.

Examination of the results of recent low-temperature X-ray crystal structure studies indicates that isotropic U values (mean-square vibrational amplitudes) of hydrogen atoms in small to medium-sized organic molecules are typically in the range 150–300×10^{-4} Å^2 at temperatures around 100 K (refs 4–10). They are usually larger than equivalent isotropic U values of the heavier atoms, partly because of the effect of internal molecular motions and partly because the hydrogen atoms tend to be situated on the outside of the molecules and hence further from the molecular rigid-body librational axes. The corresponding reported standard deviations of U_H (as derived by least-squares analysis) are typically ~30–40×10^{-4} Å^2 for reasonably good quality 100 K measurements and are perhaps as low as, say, 15–20×10^{-4} Å^2 for data sets of the highest quality available.

This is about the precision level that would be required to distinguish isotropic U of protium from that of deuterium at the 2σ (98% probability) level. For example, from tables of

Table 1 Isotropic U values ($\times 10^4$) for hydrogen atoms obtained by least-square analysis from data sets I, II and III with different weighting schemes

Bond distances obtained from the same calculations and involving the hydrogen atoms are also given. Estimated standard deviations are in parentheses.

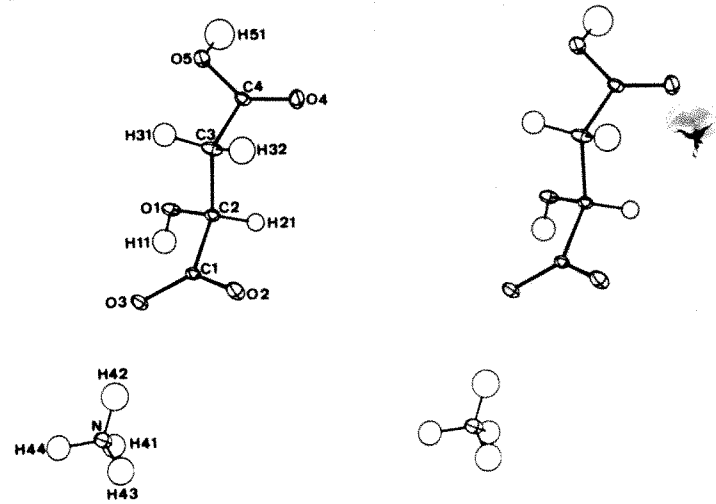

Fig. 1 Stereo view of molecule, showing atomic numbering. Vibrational ellipsoids are based on data set II and are drawn at the 50% probability level[21].

molecular vibrational frequencies for propane and 2,2-D_2-propane[11], the equivalent isotropic U_H and U_D can be estimated to be 119×10^{-4} Å for the CH_2 group and 84×10^{-4} Å^2 for the CD_2 group at 100 K. The difference of 35×10^{-4} Å^2 should be detectable by X-ray diffraction even if the presence of various systematic errors in this method could raise questions about the absolute level of the U_H values obtained.

We decided to try to determine by X-ray analysis the relative configuration of the two stereogenic centres in deuterium-labelled malic acid obtained by enzymatic addition of D_2O to fumaric acid. Although the answer to this stereochemical question was given more than 20 yr ago[12,13], we took the problem up again for methodological reasons, not because of any doubts about the earlier conclusion. Meanwhile an independent confirmation has been provided by a neutron diffraction analysis of the crystalline (+) (*R*)-α-phenylethyl ammonium salt of 2*S*-3-D-malate[14] prepared enzymatically from fumaric acid in a similar way as in the present study. Malic acid itself does not seem to yield suitable well-formed crystals, and we finally settled on the mono-ammonium salt[15] as the best candidate for an accurate low-temperature X-ray diffraction study, a choice that in retrospect may not have been optimal for reasons discussed below.

First, to test whether standard deviations of the structural parameters from such an experiment were reproducible, we measured two independent low-temperature data sets for the undeuterated compound: different crystal specimens, different diffractometers, different low-temperature devices, slightly different temperatures (~95 K), and different limiting reflection spheres. We refer to these as data sets I (extending to sin $\theta/\lambda = 0.90$ Å^{-1} at 93 K) and II (extending to sin $\theta/\lambda = 1.19$ Å^{-1} at 95 K).

The results obtained with these two data sets do not differ in any important respect. As far as the heavy atoms are concerned, atomic positions agree within a few 10^{-4} Å and vibration parameters within a few 10^{-4} Å^2. The hydrogen positions and isotropic U values are sensitive to the scattering factor and weighting system used in the least-squares analyses. Indeed, as Table 1 shows, the variations in the U_H values produced by changing the weighting system within data set II are as large as, or sometimes even larger than, the differences between values obtained from the two data sets using the same (unit) weights. For atom numbering see Fig. 1. The hydroxyl and carboxyl hydrogens, which are engaged in strong hydrogen bonds, are less well defined than the others and have much larger U_H values in both analyses. The ammonium hydrogens, which are also engaged in hydrogen bonds, have larger U_H values, presumably because of rigid-body librational motion of the ammonium group. For the three hydrogen atoms attached to carbon, there is nearly perfect agreement between the U_H values obtained from the two data sets using the same (unit) weights (see Table 1).

This comparison encouraged us to measure diffraction data for a crystal of the mono-ammonium salt of a malic acid sample prepared by enzymatic addition of D_2O to fumaric acid by means of a fumarase preparation from pig heart (Böehringer, Mannheim). Our target was the determination of the relative configuration of the two stereogenic centres, the traditional one at C(2) bearing the hydroxyl group and the new one resulting from isotopic substitution at C(3).

Considerable pains were taken to ensure that the diffraction data for the deuterated crystal (data set III) were measured as closely as possible in the same conditions as data set II for the undeuterated compound. Indeed, the two sets of diffraction measurements including unit-cell dimensions and their temperature dependence are so similar that they could easily be taken for duplicate sets of measurements for the same compound. A parallel, almost perfect correspondence holds for the positional and vibrational parameters of the heavy atoms derived from the two data sets with matching weights (Table 2). In particular, the U_{ij} components of the heavy-atom vibration tensors agree to within a few 10^{-4} Å^2 units. However, some of the differences, although small, are systematic. First, the *b* axis of the deuterated crystal is measurably (~0.01 Å) longer than that of the undeuterated crystal. This is the direction with the largest coefficient of thermal expansion and is perpendicular to the well-defined layers of molecules that constitute the crystal structure. Table 2 shows that a corresponding increase in the mean-square vibrational amplitudes U_{22} of the heavy atoms in this direction is just detectable.

The U_H values obtained from data sets II and III show greater variation but they could still also be taken as belonging to the same compound. However, given that one of the two methene atoms is protium and one deuterium, the heavier isotope can be identified as H(32) with high probability. On going from data set II to data set III this atom shows a decrease in U_H amounting to $30–50 \times 10^{-4}$ Å^2, depending on the weighting system, whereas its partner H(31) shows nearly constant behaviour. As far as the other hydrogen atoms in this comparison are concerned, some show a slight decrease, some an increase, and some erratic behaviour. Given that the configuration at C(2) is *S*, the one at C(3) is then assigned as *R*, in agreement with previous conclusions[12–14].

Unfortunately, the standard deviations of the vibration parameters are ~50% larger than we had hoped to achieve. One

* Standard deviations are in parentheses.

reason for this is the markedly anisotropic character of the molecular translational vibration tensor **T**, due to the strongly layered nature of the crystal structure. For a given atom type, standard deviations of vibrational parameters are closely linearly dependent on the vibrational parameters themselves. Thus for the carbon atoms from data set II (unit weights, Table 2) $\sigma(U_{ii}) = 8.9 + 0.00908\ U_{ii}$ (units of 10^{-5} Å^2) and for the hydrogen atoms (unit weights, Table 1) $\sigma(U) = 17.2 + 0.00630\ U$ (units of 10^{-4} Å^2).

A general reduction of the U_H values would therefore have been very helpful in reducing $\sigma(U_H)$ towards the desired level. This is one reason for thinking that mono-ammonium malate, with its strongly layered crystal structure, may not have been an ideal choice for our experiment. It is also unfortunate that the methene carbon C(3) is the one that shows the largest vibrational motion, a motion that is unavoidably transmitted to the hydrogens it carries. Nevertheless, our experiment suffices to show that with present measurement techniques, the distinction by X-ray diffraction between protium and deuterium atoms in a medium-sized organic molecule is just possible.

Even with large and accurately measured data sets, the X-ray method cannot be expected to match neutron diffraction in its ability to distinguish between protium and deuterium. However, the much wider availability of the X-ray method calls for a critical examination of its potentialities in this direction. We therefore draw attention to several points that will have to be considered by anyone hoping to improve on our work.

First, the crystal chosen for study should have smaller, less anisotropic, vibrational parameters than the one we chose. A slight gain could have been achieved with our crystals by lowering the temperature, but probably not enough to make a significant improvement.

The use of a noncentrosymmetrical, chiral crystal for an experiment of this kind can hardly be avoided as the isotopically labelled, enantiomerically-pure compound must crystallize in a chiral arrangement. At most, crystals of such a compound could be pseudo-centrosymmetric. However, there are well known difficulties associated with the refinement of nearly centrosymmetric structures in noncentrosymmetric space groups[16]. From a symmetry breakdown involving merely a difference between U_H values of two hydrogen atoms, the chance of a successful resolution seems to be remote.

The weighting problem also merits more careful attention than we have devoted to it. The problem with 'normal' weights (inversely proportional to variances) is that too large a weight is assigned to the weak, low-order reflections, which are just the ones most affected by the insufficiency of the free-atom formalism. The contamination of the resulting atomic parameters by the deformation density is especially severe for the hydrogen atoms, leading to the characteristic displacement of these atoms towards their bonded partners and also to less easily recognizable errors in the vibration parameters. These errors in the hydrogen parameters reduce the value of the weighted residual $\Sigma\omega_i(\Delta F_i)^2$ and hence of the standard deviations as estimated from the least-squares analysis.

Refinements using only high-order reflections give positional and vibrational parameters that differ perceptibly from those obtained from full-data refinements[17]. Provided that the high-order data are sufficiently extensive and accurate, the so-derived parameters are less contaminated by the valency electron density and hence, in general, closer to the true values (that is, those obtainable from a neutron-diffraction experiment). High-order refinements on data sets II and III (HO, Table 3) led to heavy-atom parameters with estimated standard deviations less than half of those derived for the full-data refinements and listed in Table 2. The C(2)–H(21) distance refined to 1.08(2) and 1.10(3) Å respectively, that is, virtually to the correct value. The other C–H, N–H, and O–H bond distances still showed deviations (mostly shortenings) of 0.03–0.10 Å. Thus, the high-order reflections contain considerably more signal from H(21) with its appreciably lower U_H than from the other hydrogen atoms. In fact, as Table 1 shows, there is an evident correlation between apparent C–H bond length and U_H: the smaller the C–H distance, the smaller the U_H. This introduces an additional element of uncertainty into the determination of the latter quantities. One possibility is to constrain the C–H, N–H and O–H bond distances to their correct values. This leads to U_H values that are larger, have larger standard deviations, but are more uniform

Table 3 Experimental details for three sets of X-ray diffraction measurements on mono-ammonium 2*S*-malate (data sets I, II) and mono-ammonium 2*S*-3-D-malate (data set III)

$R(F)$	0.021	0.023	0.017	0.023	0.015
$R_w(F)$	0.024	0.029	0.017	0.032	0.015

between the two data sets II and III (except, of course, for H(32), which shows a drop of 50×10^{-4} Å^2). In retrospect, given that the hydrogen atoms H(31) and H(32) do not scatter significantly at high angles, our experimental effort might have been better spent by making two duplicate sets of measurements out to a lower sin θ/λ limit, say, 0.9 Å^{-1}.

Another question concerns the possibility of measuring the components of the anisotropic tensor $\mathbf{U}_H$ instead of just the contracted scalar U_H, for the vibrational amplitudes of the hydrogen atoms can be expected to be far from isotropic. The difficulties are formidable, and no attempt to accomplish this from X-ray diffraction data has been convincing.

Finally, there is the question of whether anything might be gained by expressing the static deformation density in parametric form, and refining the additional parameters together with the usual positional and vibrational parameters by the least-squares method. If sufficient data were available, the decrease in the weighted residual could more than compensate for the increase in the number of parameters, leading to a lowering in the standard deviations of the positional and vibrational parameters.

The X-ray measurements were carried out on two different Enraf-Nonius CAD4 diffractometers each equipped with a graphite monochromator (Mo$K\alpha$ radiation, $\lambda=0.7107$ Å) and a modified Enraf-Nonius gas-stream low-temperature device. Temperature fluctuations monitored by a thermocouple for data set I and by a PT100Ω resistor for data sets II and III were less than ±0.5 K during the experiments.

The two compounds were recrystallized by slow evaporation of an aqueous solution at about 293 K. Different crystal specimens were used for data sets I and II (space group $P2_12_12_1$). Unit-cell dimensions at 95 K were obtained by least-squares refinement of setting angles for 24 reflections with 2θ values in the range 96° to 105°: data set II, $a=7.6386(7)$, $b=8.0254(7)$, $c=10.5873(8)$ Å; data set III, $a=7.6366(6)$, $b=8.0351(8)$, $c=10.5840(8)$ Å. Integrated relative intensities were obtained by $\omega, 2\theta$ scans.

The room-temperature coordinates[15] served as starting point for our least-squares refinements (X-ray-system[18]). Final positional and vibrational parameters, listed in Table 2, are based on full-matrix least-squares analyses using scattering factors for neutral atoms[19,20] and including an isotropic extinction correction. Additional experimental details for the three data sets are summarized in Table 3.

We thank Professor Duilio Arigoni for encouragement and for comments.

Microgranitoid enclaves in granites—globules of hybrid magma quenched in a plutonic environment

R. H. Vernon

School of Earth Sciences, Macquarie University, North Ryde (Sydney), New South Wales 2113, Australia

Microgranitoid enclaves (autoliths, cognate xenoliths, mafic inclusions) are common in high-level granitoid plutons. They have relatively fine-grained igneous (microgranitoid) microstructures[1], and many show evidence of having flowed in a magmatic condition[2]. These features counter interpretations that the enclaves represent transformed solid fragments of diverse wall rocks[3–5] or restite[6–11]. An alternative interpretation is that the enclaves represent globules of mafic magma that have mingled ('commingled') and quenched in the granitoid host magma[12–16]. A detailed review of the literature, occurrence, morphology and composition of microgranitoid enclaves strongly supports this view, but indicates that the enclave magmas range in composition from mafic to felsic, and that magma-mixing may be involved in their formation[17]. I summarize here the main features of microgranitoid enclaves and briefly outline the possible processes leading to their incorporation as magma globules in the host granitoid.

The microgranitoid enclaves occur in both I-type and S-type high-level granitoid plutons[17,18]. Their abundance is not related to pluton contacts nor the number of hornfels xenoliths[2], and they are typically much more abundant than hornfels or other xenoliths[17]. Their distribution may be locally uniform, but is commonly irregular, and they may be concentrated in swarms[2]. They are generally unrepresented among the exposed country rocks[6].

The microgranitoid enclaves typically have rounded to ovoid shapes[1,2], though sub-angular and, more rarely, angular enclaves may be present[2]. Some have cuspate margins, with lobes convex towards the host granitoid. Elongate enclaves are markedly ellipsoidal to lenticular, and are aligned in areas of the granitoid that show a prominent primary flow foliation[2], especially near the margins of the pluton[7]. Their alignment and degree of elongation correlate with the intensity of the flow foliation in the host granitoid[2,17]. Neither enclave nor granitoid show microstructural evidence of crystal plasticity or recrystallization, so that the extension appears to have been accomplished by relative movement of crystals and melt; that is, when they were in a magmatic condition[17,19].

The enclaves generally have uniform, random microstructures, though some have finer-grained margins. Some have flow alignment of plagioclase or hornblende crystals, which may be parallel to the enclave margins and may be deflected around phenocrysts. The enclave microstructures are typical of fine- to medium-grained igneous rocks, consisting commonly of euhedral phenocrysts of zoned plagioclase, with or without quartz, biotite, hornblende (in I-types) or orthopyroxene ± cordierite (in

S-types), set in a groundmass rich in biotite and euhedral laths of zoned plagioclase, commonly with interstitial to poikilitic quartz, and/or K-feldspar[17]. They typically contain apatite needles, indicative of magma quenching[20]. They have compositionally and microstructurally similar counterparts in calc-alkaline volcanic rocks[13,14,21,22]; many of these contain interstitial glass and some have skeletal, zoned crystals of hornblende and plagioclase, indicating a magmatic condition[13,14,22].

The enclaves are darker and finer-grained than their host granitoids, but although some are mafic[16], most are intermediate to silicic[23]. Many compositional varieties may occur together. The mineral assemblages in the enclaves are generally the same as those in the host granitoid, but the proportions and compositions of the minerals are typically different[2,17].

Magmatic orthopyroxene + cordierite + plagioclase in the microgranitoid enclaves of the S-type Cowra Granodiorite, New South Wales, Australia[18], indicate crystallization at relatively low confining pressures (100–200 MPa)[24]. If these enclaves are representative, microgranitoid enclaves appear to crystallize at pluton emplacement levels, which agrees with the observation that they are restricted to relatively high-level plutons[25].

The inference that the enclaves were globules of magma at the time that the flow occurred can explain the typical rounded to cuspate shapes of the enclaves. The rounded shapes appear to be primary, rather than due to rounding of angular, solid fragments, because nearby hornfels xenoliths generally show little or no rounding. The more angular enclaves could be fragments of solid, quenched igneous rocks, but they could also be magma fragments, because magma may break (like pitch) under rapidly applied stress[26].

The relatively fine-grained microstructures indicate relatively rapid crystallization; that is, quenching of magma in the plutonic environment. Examples of mafic (mafic to intermediate) magma quenched against felsic magma are common in volcanic[22,26–28], subvolcanic[12,26,29–31] and plutonic[16,19,29,32–37] environments, as discussed in detail elsewhere[17]. The process involves magma mingling, whereby rounded to cuspate globules and streaks of the more mafic magma become dispersed through the felsic magma. The more mafic magma crystallizes more rapidly (forming finer-grained aggregates) than the felsic magma, because it is more undercooled than the felsic magma[22], once thermal equilibrium between the two has been established. Mafic enclave magmas would be much more strongly undercooled than their graintoid host magmas[22]. However, even where the enclave and granitoid magmas are fairly similar in composition, the more mafic enclave magma can crystallize more rapidly, because small differences in the degree of undercooling can give rise to marked increases in nucleation rate and marked decreases in growth rate[17].

The origin of the magma that produced the enclaves is a matter for speculation, as examples of magma mingling show only that magmas can intimately coexist, not how they originated[11]. Though felsic and more mafic calc-alkaline magmas are chemically miscible[37–40], they can remain separate[38], particularly if small volumes of the more mafic magma are enclosed in large volumes of felsic magma and if stirring is minimal[39,40], because chilling increases the viscosity of the more mafic globules, as well as promoting rapid crystallization.

Enclave magmas conceivably could be derived from: (1) partly crystallized, quenched margins of the granitoid[18,41] (if this can account for the evidence of hybridism and the observed compositional range of enclaves in a single pluton), (2) repeated mingling of a variety of more mafic (?)hybrid magmas injected into, or fortuitously encountered by, the granitoid, or (3) a more mafic lower layer in the pluton that is partly mixed with the granitoid magma[17]. Careful isotopic studies could conceivably indicate whether the enclave magmas are closely related to the granitoid magma[42] (for example, either differentiates of it or separate batches of (?)hybrid magma from the same or an isotopically similar source) or whether they involve contributions from unrelated magmas[22].

One way of producing the observed compositional variation of the enclaves is by magma mixing, which involves homogenization of the two melts (in contrast to magma mingling). The common presence of plagioclase with resorbed or dendritic cores, K-feldspar megacrysts with oligoclase rims, and rounded quartz xenocrysts with fine-grained mafic rims indicates that many enclave magmas are related in origin to rocks showing mineralogical evidence of hybridism[17,28,29], for example, the Skye marscoite, for which magma mixing is commonly postulated[29,43]. Therefore, the enclave magmas may be products of magma mixing[15], either in the same pluton[17], or at a site removed from the actual magma mingling in the pluton, as commonly appears to be so for clear examples of magma mingling[29,30].

Reid *et al.*[16] recently presented clear evidence of the mingling of felsic magma with more mafic magma globules in the Sierra Nevada, California, adding that solution and disintegration of the resulting enclaves contaminated the surrounding granitoid. However, in my experience, microgranitoid enclaves typically show little or no evidence of disintegration, and the surrounding granitoid is generally not obviously modified[36]. Furthermore, disintegration of enclaves should disseminate finer-grained material than is typical of granitoids. The tendency of enclaves to be more abundant in more mafic granitoids[8,16] may be due simply to local accumulation of enclaves and precipitated crystals[44]. The common coexistence of enclaves of variable composition[17] and the microstructural evidence of hybridism suggest that the compositional variety of the enclave magmas was produced away from the exposed site of final mingling. Furthermore, reports of 'lamprophyric' dykes with corroded xenocrysts, resembling enclaves in adjacent granitoids[29,45], suggest that enclave magmas can exist either independently of, or as a separate layer in, their host granitoid magma bodies.

Inverse relationship between Sr isotope diversity and rate of oceanic volcanism has implications for mantle heterogeneity

Rodey Batiza

Department of Earth and Planetary Sciences and McDonnell Center for the Space Sciences, Washington University, St Louis, Missouri 63130, USA

Cohen and O'Nions[1] noted that basalts from the Mid-Atlantic Ridge (MAR) display greater diversity of Pb, Nd and Sr isotopes than do basalts from the East Pacific Rise (EPR). They attributed this difference not to greater isotopic heterogeneity beneath the MAR, but rather to more effective mixing (to eradicate heterogeneity) beneath the EPR. Allègre *et al.*[2] reached the same conclusion on the basis of isotope data including noble gas isotopic data. To test this idea further, I compare here the average spreading rate of nine portions of the mid-ocean ridge system with the measured $^{87}Sr/^{86}Sr$ diversity of basalts. This shows that the maximum observed $^{87}Sr/^{86}Sr$ diversity is inversely proportional to spreading rate. Furthermore, globally averaged eruption rates for mantle-derived rocks of intra-oceanic island arcs, ocean islands and the mid-ocean ridge system exhibit a negative correlation with $^{87}Sr/^{86}Sr$ diversity. These results suggest that the upper mantle is everywhere heterogeneous on a small scale and that the extent of observed heterogeneity is a function of mixing. Independent geophysical and petrological evidence for the existence of steady-state crustal magma chambers beneath fast-spreading ridges and their absence below slow spreading ridges favours this hypothesis because mixing is enhanced by the presence of a magma chamber. Alternatively, mixing during melt production in the mantle, during melt segregation or during ascent could also result in the observed patterns if the degree of mixing is related to eruption rate. Large heterogeneities (mantle plumes?) are required to explain why isotopic variations are well correlated geographically in some places but not in others.

Several workers have suggested that the sub-oceanic mantle source for basalt melts is ubiquitously heterogeneous on a small scale[3–6]. A 'plum pudding' mantle of this type can, on melting, produce suites of basalts with variable $^{87}Sr/^{86}Sr$. The variability depends partly on the sizes of the isotopically heterogeneous regions compared with the size of the region undergoing batch melting. Batch melting of regions that are large compared with the sizes of isotopically heterogeneous domains will produce a homogeneous melt with isotopic characteristics that approach those of the bulk source. On the other hand, batch melting of smaller regions produces melts that selectively sample the heterogeneities. Melting of several such small isolated regions would produce a suite of melts with diverse isotopic characteristics that, as a group, reflect the isotopic diversity of the source rather than its average bulk characteristics.

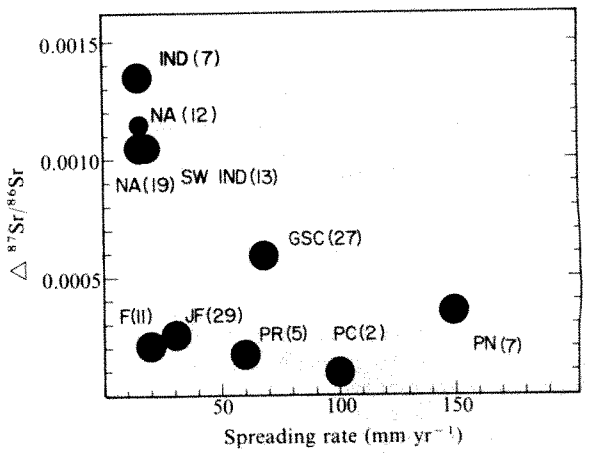

Fig. 1 Plot of $^{87}Sr/^{86}Sr$ range (Δ) against spreading rate for the data of Table 1. Numbers in parentheses are the number of samples. IND, Indian Ridge; NA, North Atlantic; SW IND, south-west Indian Ocean Ridge; F, FAMOUS Area; JF, Juan de Fuca Ridge; GSC, Galapagos Spreading Centre; PR, Pacific-Rivera (21°N); PC, Pacific–Cocos and PN, Pacific Nazca Ridge. For available high-precision analyses of glasses and carefully leached samples, there is an inverse correlation between the maximum strontium isotope diversity of MORB and the spreading rate.

Likewise, if the size of the melt region is held constant, melts produced by batch melting of plum pudding mantles would be expected to have isotopic characteristics that vary as a function of the extent of partial melting[4,7,8]. Small degrees of partial melting would selectively sample mangle domains having lower solidus temperature because of enrichments in volatiles, large ionic lithophile (LIL) elements and ^{87}Sr and larger extents of melting would result in dilution of this melt fraction with melt from more refractory LIL-poor mantle domains[9,10]. Suites of isotopically diverse melts could be produced in this way by lateral, depth or temporal variations in the extent of partial melting.

Isotopically diverse melts that are generated simultaneously in neighbouring regions of a plum pudding mantle by either variable extents of batch melting or variable size of melt region or both, may ascent and erupt without mixing to produce isotopi-

Table 1 Sr-isotopic, spreading rate and eruption rate data

Location	Highest $^{87}Sr/^{86}Sr$	Lowest $^{87}Sr/^{86}Sr$	Δ $^{87}Sr/^{86}Sr$	Data sources	No. of samples	Spreading rate (mm yr^{-1})

* Mean analyses.
† From ref. 18.

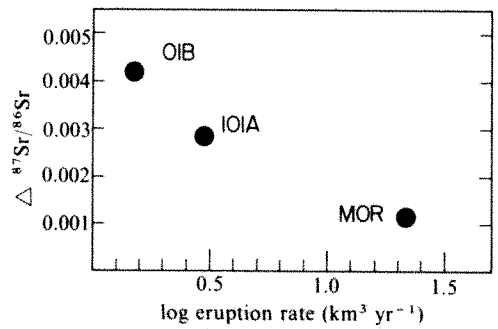

Fig. 2 Plot of $^{87}Sr^{86}Sr$ range (Δ) against global, time-averaged eruption rate for mid-ocean ridges (MOR), ocean islands (OIB) and intra-oceanic island arcs (101A)[18] Sr-isotope compilations are from ref. 7.

cally diverse lava suites. Alternatively, mixing of these diverse batches in the mantle or crust could partly or completely homogenize the diverse melts.

Table 1 is a compilation of published ranges of high-precision $^{87}Sr/^{86}Sr$ data for mid-ocean ridge basalts (MORB) with corresponding spreading rates[11–14]. These are measured values for fresh glasses and carefully leached crystalline basalts. Figure 1 shows that the maximum observed range of $^{87}Sr/^{86}Sr$ is inversely correlated with spreading rate for MORB; smaller ranges of variation are possible for smaller geographical subsets or may be artificially created by insufficient sampling. Ideally, of course, this sort of comparison is most meaningful if normalized to equal ridge crest lengths that are sampled with uniform density. Unfortunately, the available data are too fragmentary for this, or for rigorous statistical analysis of the variation along all ridge crest segments. Note that Fig. 1 contains data for ridge crest segments that display coherent geographical patterns of isotope variation (like the northern MAR[15,16]) as well as slow-spreading ridges that do not (like the south-west Indian Ocean Ridge.[17])

Table 1 also gives $^{87}Sr/^{86}Sr$ data compiled by Morris and Hart[7] for mantle-drived intra-oceanic island arcs, oceanic islands and the mid-ocean ridge system together with globally-integrated average eruption rate estimates of Crisp[18]. For these data, average eruption rate is inversely correlated with diversity of $^{87}Sr/^{86}Sr$ (Fig. 2). This agrees with the MORB data if the eruption rate at mid-ocean ridges is proportional to spreading rate.

Future additional sampling and analyses will be required to determine whether the patterns of Fig. 1 hold up or are merely artefacts. For future sampling of ridge crests it is important to distinguish between the axes of normal ridge crests and small, isotopically diverse seamounts that may be present near the ridge[8]. In addition, recently discovered petrological effects at ridge transform intersections[19–21] may be important, so it is crucial to know the locations of transforms and ridge off-sets[22,23].

If these general patterns are confirmed, there are several possible explanations for their existence. It is possible, of course, that the mantle sources of slow-spreading ridges are simply more heterogeneous than the sources below fast-spreading ridges. Alternatively, the extent of contamination of basalt magma may be related to spreading rate[24]. These seem unlikely, however, and I prefer to interpret these patterns in terms of melting of a plum pudding mantle associated with or followed by varying amounts of homogenization caused by mixing. This is reasonable in view of the large amount of independent geophysical and petrological evidence for the spreading rate dependence of steady state crustal magma chambers beneath ridge axes[25–29]. It is also possible, of course, that mixing takes place in the mantle during melting[30–32], segregation[33–35] or ascent[36]. Evaluation of this possibility must await better understanding of the thermal structure beneath ridges, their temporal variability and possible feed back and buffering of the thermal and rheologic properties of the mantle by melting and magmatic ascent processes[37–39]. If our preferred interpretation of the pattern in Figs 1 and 2 is correct, it has important implications for the nature and size of mantle reservoirs, their convective mixing[40,41] and their thermal and differentiation histories.

This study was supported by the NSF and ONR. I thank numerous colleagues for discussion.

Particulate and dissolved vanadium in the North Pacific Ocean

R. W. Collier

College of Oceanography, Oregon State University, Corvallis, Oregon 97331, USA

The distributions of dissolved trace elements in the oceans result from a complex series of biogeochemical processes. Historically, most models describing the cycles of these elements have been formed around high quality data for the distributions of the dissolved elements[1]. I report here a detailed vertical profile of particulate vanadium and estimate its particle-associated flux. This flux suggests a surface depletion of dissolved vanadium which is verified by the first detailed determinations of dissolved vanadium in several profiles from the Pacific Ocean.

Particulate matter was collected from the upper 1,500 m of the Panama Basin by a large volume filtration system (LVFS)[2]. The samples were collected in July 1976 and again in March 1979 from the same location, 0° 44′N, 86° 10′W. The chemistry, biology, and vertical flux of material in the 1976 samples have been reported elsewhere[3] and a discussion of the 1979 samples is in preparation. Samples for dissolved vanadium analysis were collected from this site and several other locations in the North Pacific Ocean (Table 1).

The concentration of particulate vanadium in the >53 μm particles is shown in Fig. 1. The basic form of these two vertical profiles is driven by the distribution of total particulate mass[3]. The strong surface maximum is associated with the primary production of biogenic particulate matter. However, terrigenous material is also an important carrier of particulate vanadium. The compositions of fine suspended particulate matter[4] and material from sediment traps in the deep Atlantic[5] show excellent correlations between vanadium and aluminium at crustal ratios. Although there was significantly more biogenic and terrigenous particulate matter in the water column during March 1979, the concentration of particulate vanadium was higher during July 1976. The V/Al ratio in the surface sample from the 1976 Galapagos profile was 2.4×10^{-2}, which is more than one order of magnitude higher than the crustal ratio (8.5×10^{-4}). The ratio in the deeper samples dropped rapidly towards the crustal value as the biogenic material was remineralized. The same ratio in the March 1979 samples was near to the crustal value throughout the water column. The V/Al ratios in particles collected from sediment traps in the eastern tropical Pacific and from the underlying sediments (J. Dymond and R. C. unpublished data) are also near the crustal values. The flux to these traps (~0.7 nmol V cm^{-2} yr^{-1}) also matches the accumulation rate of vanadium in the sediments. This emphasizes the refractory

Samples from MANOP, Site S (11°N, 140°W) were collected in May 1979. Galapagos samples (0°44′ N, 86°10′ W) were collected in March 1979, and those from the subarctic Pacific (50° N, 150° W) in June 1981.

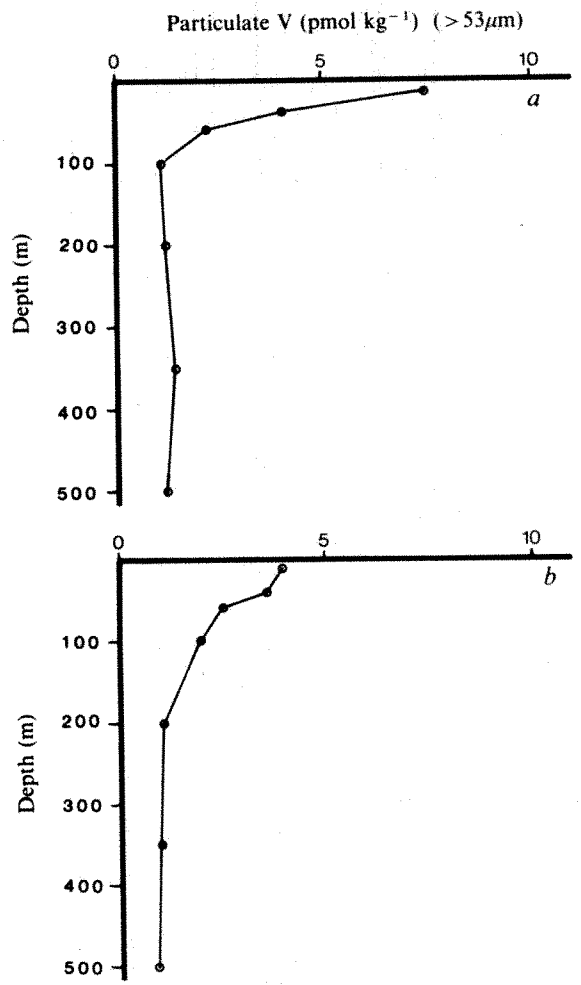

Fig. 1 Concentration of vanadium (pmol V per kg seawater) in particles larger than 53 μm. The samples were collected *in situ* by a filtration technique[2] that separates three particle size fractions (<1, 1–53, and >53 μm) from large volumes of water (2–20 m^3). Thus, the sampling method permits the collection of larger sized particles which, although rare, settle rapidly enough to dominate the vertical mass flux in most environments[1–3,25]. The size–frequency distribution of the particulate matter on the filters is determined microscopically and, when combined with estimates of settling rates for each particle class, yields an estimate of the total vertical mass flux. This is combined with the bulk chemical composition of the particulate material to estimate the flux of each chemical component. Particulate vanadium was determined by instrumental neutron activation analysis[26] of the >53 μm size fraction. Data shown are samples from the Galapagos site collected in: *a*, July 1976; *b*, March 1979.

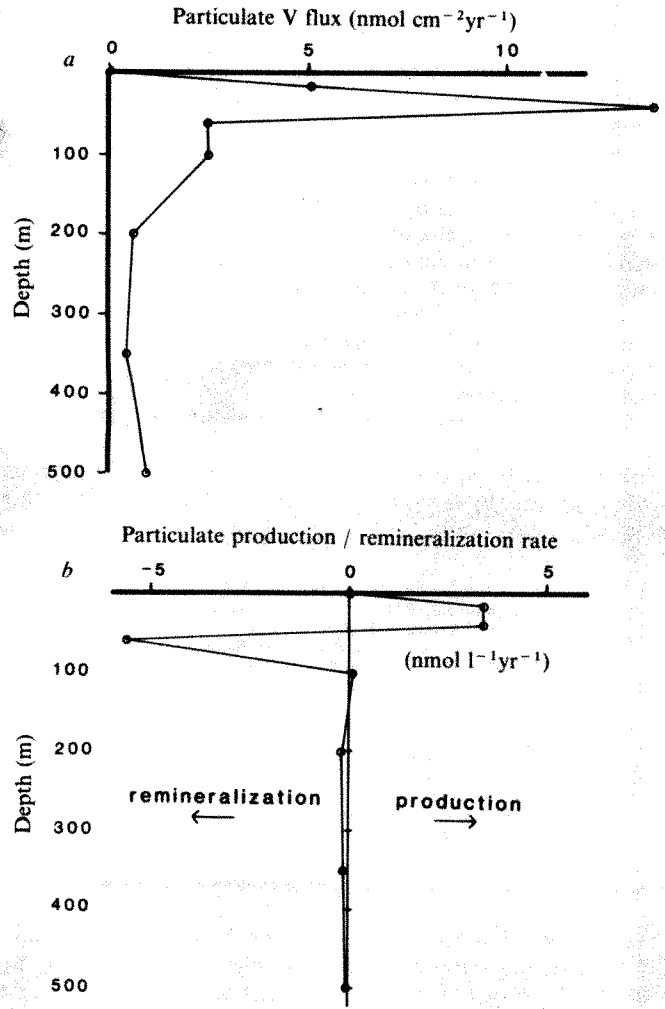

Fig. 2 *a*, Calculated vertical flux of particulate vanadium; *b*, resulting production or remineralization of vanadium due to changes in the particle flux.

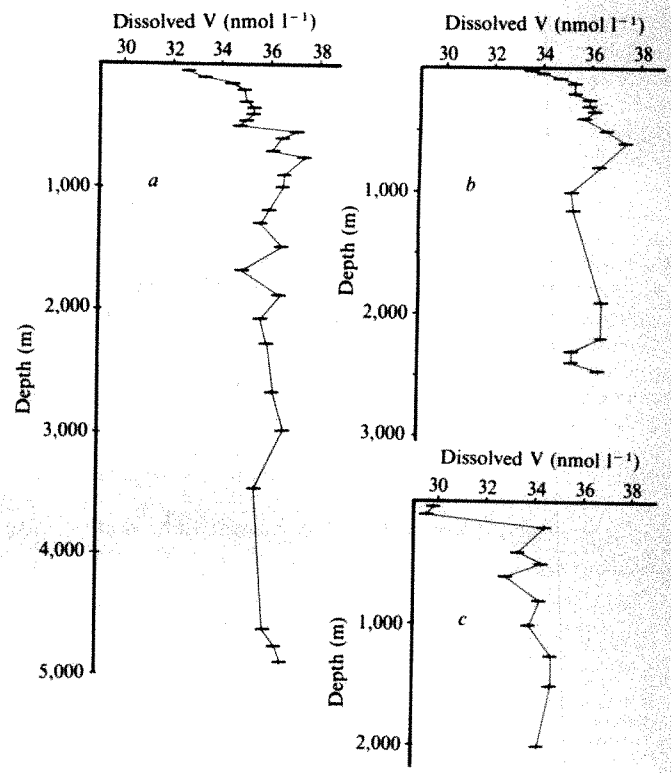

Fig. 3 Dissolved distributions of vanadium showing surface depletions: *a*, MANOP site S; *b*, Galapagos site; *c*, subarctic Pacific. The analysis for dissolved vanadium was made by atomic absorption spectrometry using a graphite furnace atomizer. For preconcentration of the vanadium, the acidified samples were buffered to *p*H 4 and the trace elements were co-precipitated with cobalt–APDC[16]. The method recovers both V(IV) and V(V) oxy-anions from seawater with an efficiency of 80%. The limit of detection using 35 ml of seawater is 1 nmol V per kg seawater; the precision is 0.4 nM (1σ) at 35 nM vanadium.

nature of the vanadium in these deep samples. Clearly, the 'biogenic' vanadium seen near the surface in the 1976 samples is very labile and does not contribute significantly to the deep flux.

This region of the oceans is subject to large seasonal as well as inter-annual variations in productivity associated with the complex equatorial current systems[6]. The 1976 data were collected during a low productivity event caused by El Niño conditions[3] which may have resulted in the observed differences between the two particulate vanadium profiles. The nature of the vanadium association with organic particulate matter is unknown, as is the case with most other trace metals[7]. Although there is a vanadium(III) oxygen carrying protein in some ascidians[8], its significance to pelagic vanadium cycling is doubtful. There may, however, by labile vanadium enrichments in related organisms such as salps. Other organovanadium complexes (such as tetrapyrroles) found in marine sediments[9] are stable diagenetic products of prophyrins.

Vertical flux estimates for vanadium from the 1976 profile are shown in Fig. 2*a*. These fluxes are based on the concentration data (Fig. 1*a*) and estimates of the bulk mass flux[3]. The flux reaches more than 10 nmol V cm^{-2} yr^{-1} at 60 m but drops off by an order of magnitude below 200 m depth. Based on the observed particle compositions[3], vanadium behaviour in the upper water column parallels the formation and decomposition of particulate phosphorus at a constant V/P ratio of 4×10^{-3}. Using this ratio with an estimate of the global flux of particulate phosphorus[10] (0.87 μmol P cm^{-2} yr^{-1}) yields an estimate of the flux of vanadium out of the surface ocean of 3.5 nmol V cm^{-2} yr^{-1}.

Assuming that the vertical profile is in steady state, a change in the flux as a function of depth requires *in situ* production or remineralization of particulate vanadium (Fig. 2*b*). If this change occurs solely through exchange with dissolved vanadium, the estimated fluxes also represent the dissolved depletion or regeneration rate. This rate can be compared with other fluxes in the marine vanadium cycle by using a simple vertical two-box model[7,11]. Depletion of vanadium from surface waters must be balanced by primary inputs, including riverine and atmospheric inputs as well as physical exchange with deeper water. The riverine[12] and atmospheric[6,13] inputs probably supply $\leqq$0.4 nmol V cm^{-2} yr^{-1} such that at least 85% of the particulate flux estimated from the LVFS data must be supplied by exchange of depleted surface water with the deep ocean. At an average volume exchange rate of 3.5 m yr^{-1} distributed over the ocean surface, the surface water reservoir should be depleted in vanadium by about 8 nmol l^{-1} relative to the deep reservoir.

When these flux estimates were completed[14], very little data existed for the concentration of vanadium in seawater[15], and none had been generated using currently-accepted sampling methods. Especially lacking were any high-quality profiles from the Pacific. Therefore, vanadium was analysed in samples collected from the Pacific specifically for trace metal analysis. The hydrographic data and concentrations of vanadium are given in Table 1 and the distributions are presented in Fig. 3. A surface depletion of V is clearly demonstrated, although the magnitude is about one-half that predicted by the particulate data. The average 'specific' vanadium (normalized to a salinity of 35.0) was 32.7 nM in these Pacific surface waters and 36.4 nM in the deep Pacific. Based on the pelagic data, the residence time of dissolved vanadium in the ocean with respect to its river input[12] is $\sim 5 \times 10^4$ yr.

Significant processes affecting the concentration of trace metals at the ocean margins (such as increased scavenging, diffusion from sediments, or inputs from rivers) have been identified through the examination of surface water samples collected on transects moving away from coastal regions[16–18]. The specific vanadium concentrations in surface samples taken along a transect off California (at 39° 38′N) had an average value of 32.4 nM (similar to the pelagic values) and showed no systematic change near the coast.

The marine geochemical cycles of metals are often affected by their involvement in redox cycles[19,20]. Major concentration changes result from direct changes in solubility as a function of oxidation state and scavenging by fresh hydrous metal oxides produced near oxygen interfaces. The specific vanadium concentration within the anoxic zone of Saanich Inlet, British Columbia was ~26 nM which is somewhat lower than the pelagic value. However, there were no systematic changes in the concentration of vanadium with depth that related to other redox parameters.

These pelagic distributions are consistent with other recently reported determinations of dissolved vanadium[21–24], although a slight surface enrichment has been reported in the western North Atlantic[23]. In view of the variability of particulate vanadium seen at the Galapagos site (Fig. 1*a*, *b*), it is not surprising that some variations in its dissolved surface depletion exist. The simple box model applied to estimate the surface depletion is, at best, a crude approximation of the oceans and the 1976 data set used to derive the flux (Fig. 2) may not be representative of the mean biogenic flux of vanadium. Therefore, the factor of 2 agreement between the predicted and measured distributions is encouraging. There is certainly much more to learn about the detailed chemistry of vanadium and other metals in the oceans. This investigation demonstrates how both particulate matter and dissolved distributions can be coupled to study these biogeochemical cycles.

Radium fluxes from a salt marsh

Marsha S. Bollinger & Willard S. Moore

Geology Department, University of South Carolina, Columbia, South Carolina 29208, USA

Dissolved ^{226}Ra (half life 1,600 yr), ^{228}Ra (half life 5.7 yr) and ^{224}Ra (half life 3.64 days) activities in estuarine and coastal waters higher than values reported for open ocean or river waters have been explained by desorption and diffusion of radium from coastal and estuarine sediments[1–4]. Fluxes of radium isotopes from sediments in Long Island Sound, the Hudson River estuary, Chesapeake Bay and Winyah Bay, South Carolina, have been estimated from mass balances, diffusive bottom fluxes and desorption from suspended sediments[4–7]. These estimates may not be correct if salt marshes which are intimately associated with estuaries and the coastal ocean are an additional source or sink of radium[4]. In this study Bly Creek, a small marsh-tidal creek system near Georgetown, South Carolina, was chosen to determine the flux of ^{228}Ra and its great granddaughter, ^{224}Ra, from the sediments to the tidal creek water. We find that the highest activities of ^{224}Ra and ^{228}Ra in the tidal creek waters occur during low tide, but ^{226}Ra activity remains relatively constant throughout the tidal cycle. Fluxes of ^{224}Ra and ^{228}Ra calculated from mass balances required to support the observed activities in the creek waters and measured directly using a flux chamber are consistent. These measurements reveal a large input of radium from the marsh sediments to the overlying waters. To produce the necessary fluxes, irrigation and bioturbation must replace interstitial water in the top 5 cm of the marsh sediments every 2–3 days.

Surface water samples collected at approximately 40-min intervals over two tidal cycles were processed for radium isotope determinations[8]. Water velocity and depth were measured simultaneously. The activity ratios ^{228}Ra/^{226}Ra and ^{224}Ra/^{226}Ra were determined by γ-ray spectrometry and absolute ^{226}Ra activities were determined by radon emanation[3,4]. Absolute ^{224}Ra and ^{228}Ra activities were calculated from the activity ratios and the absolute ^{226}Ra activities. ^{226}Ra activities remained constant and net water flux was essentially zero throughout the study.

The ^{224}Ra and ^{228}Ra data describe two straight lines when plotted against the height of water at the sampling site in Bly Creek (Figs 1, 2). The highest activities of radium occur during the lowest tide heights. We conclude that this linear relationship between water depth and radium activity must represent dilution of high-activity marsh waters with low-activity ocean water. Thus, radium must be supplied to the creek waters from the marsh sediments to maintain the high activities observed at low tide. The only other potential source, groundwater, can be excluded because salinities did not vary significantly in Bly Creek during the study.

If Ra in the marsh system is in steady state, that is, if the Ra exported during ebb tide is balanced by production and release of Ra from marsh sediments, we can use mass balances to determine Ra fluxes from the sediments.

$$F_{Ra} = \frac{V_{out}Ra_{out} - V_{in}Ra_{in}}{A\Delta t} \quad (1)$$

where F_{Ra} is the flux of Ra from the sediment; V_{out} is equal to V_{in}, the volume of water exchanged during one tidal cycle; Ra_{out} is the Ra exported from the marsh (d.p.m. l^{-1}); Ra_{in} is the Ra imported from the coastal ocean (d.p.m. l^{-1}); A, is the area of marsh flooded at high tide; and Δt, is the time in one tidal cycle (12 h).

Measurements of Ra isotopes in nearby coastal waters reveal that activities of ^{224}Ra and ^{228}Ra are quite low (of the order of 0.2–0.3 d.p.m. l^{-1})[8,9] and for a first approximation can be neglected when compared with the activities observed in the marsh waters (1–3 d.p.m. l^{-1}). Thus, equation (1) simplifies to

$$F_{Ra} = \frac{V_{out}Ra_{out}}{A\Delta t}$$

Topographic data are used to estimate the volume of water

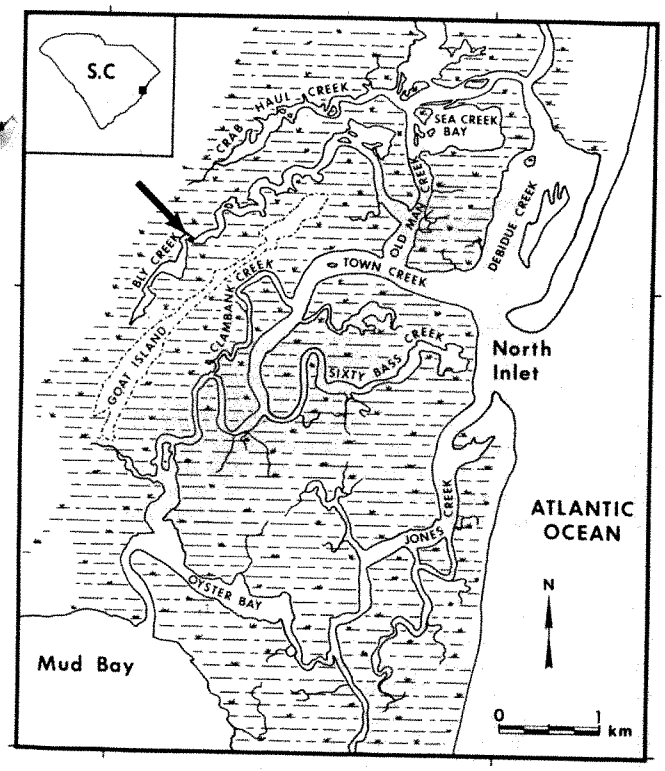

Fig. 1 Map of marsh surrounding North Inlet, South Carolina. Location of primary sampling site on Bly Creek (33°20′ N 79°12′ E) is indicated by the arrow. Bly Creek drains the sandy sediments between ancient beach ridges, one of which is labelled Goat Island.

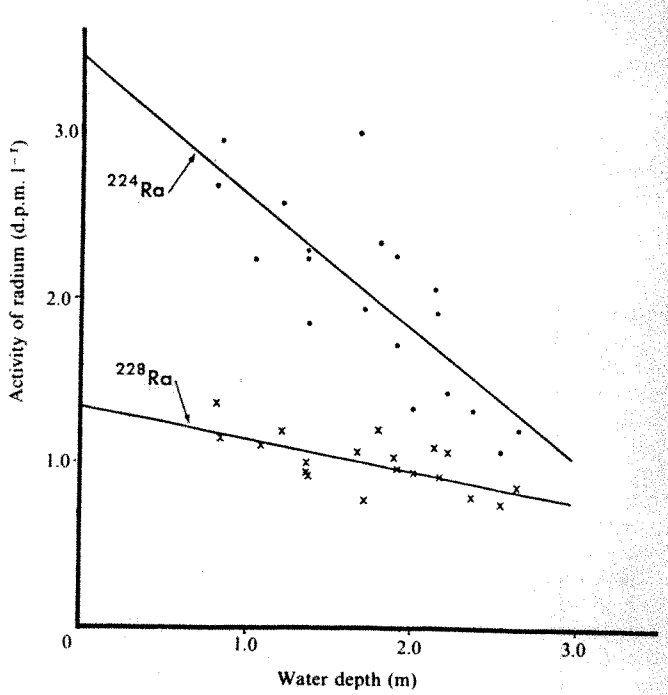

Fig. 2 The activity of radium versus the water depth in Bly Creek on 15 and 16 October 1982. Correlation coefficients for ^{224}Ra and ^{228}Ra are −0.795 and −0.667, respectively.

leaving the marsh on the ebb tide, V_{out}. The average activity of radium over one tidal cycle, Ra_{out}, is 2.1 d.p.m. l^{-1} for ^{224}Ra and 1.0 d.p.m. l^{-1} for ^{228}Ra (Fig. 2). Thus, the fluxes of ^{224}Ra and ^{228}Ra are 2×10^{-7} d.p.m. $cm^{-2}\,s^{-1}$ and 1×10^{-7} d.p.m. $cm^{-2}\,s^{-1}$, respectively.

To determine whether these fluxes are realistic, we devised a flux chamber consisting of a 25-cm diameter, 1.4-m long polyvinylchloride pipe closed at one end except for an air vent. The open end of the chamber is inserted about 15 cm into the sediment. An opening just above the sediment is connected by flexible hose to a conveniently located column which is secured near the sediment surface and filled with acrylic fibre impregnated with manganese dioxide (Mn-fibre)[10]. The apparatus is installed at low tide in an area free of surface water; as the tide rises, water passes through the Mn-fibre column to fill the chamber. The Mn-fibre strips all radium isotopes from the incoming water. At high slack tide the Mn-fibre column is replaced with a fresh Mn-fibre column. As the tide falls, any radium which may have moved from the sediment into the chamber is collected by the Mn-fibre column as water drains from the chamber. Fluxes of ^{224}Ra and ^{228}Ra obtained by this method are 6×10^{-7} d.p.m. $cm^{-2}\,s^{-1}$ and 2×10^{-7} d.p.m. $cm^{-2}\,s^{-1}$, respectively.

The fluxes calculated from the tidal cycle data agree with the fluxes measured by the chambers to within a factor of 3. Considering the assumptions used in the tidal cycle calculation and possible variation in fluxes throughout the marsh, this agreement is very good.

Decay of ^{228}Th (half life 1.9 yr) produces ^{224}Ra in the marsh sediments. Using 0.5 d.p.m. ^{228}Th cm^{-3} of sediment (based on initial analyses) gives a production term of 5.9×10^{-6} d.p.m. ^{224}Ra $cm^{-2}\,s^{-1}$ over a depth of 5 cm. We chose 5 cm as the depth from which ^{224}Ra can be derived because: (1) this is approximately the top of the dense root zone of the *Spartina*, and (2) preliminary measurements show ^{224}Ra in interstitial waters to be depleted in the top 5 cm but constant below 5 cm. Comparison of this potential source with the flux necessary to support the ^{224}Ra in the water column (from the more conservative tidal cycle data) reveals that only about one-third of the ^{224}Ra produced in the top 5 cm of sediment need be mobilized to yield the required fluxes. A similar calculation for ^{228}Ra reveals that to support the observed flux, ^{228}Ra must be removed from at least 25 cm of sediment if this is a steady state flux. However, the ^{228}Ra flux may be periodic with seasonal gains and losses of the longer-lived Ra isotopes in the sediments.

Three mechanisms may be driving this exchange process: (1) molecular diffusion, (2) advection of interstitial water from the sediments due to turbulence in the overlying water and tidal pumping, and (3) turbation and irrigation by organisms. To estimate the scale length (L) over which molecular diffusion is effective we use the relationship $L=\sqrt{D/\lambda}$ where D is the effective diffusion coefficient of Ra, 3.4×10^{-8} $cm^{-2}\,s^{-1}$ (assuming a temperature of 18 °C, a tortuosity of 2.0, and an adsorption coefficient of 100)[11–13], and λ is the decay constant of ^{224}Ra, 2.2×10^{-6} s^{-1}. Thus, the path length is 0.12 cm. Our preliminary interstitial measurements indicate that ^{224}Ra is removed from at least 40 times this depth; therefore, other factors must be increasing the exchange. Because the flux chambers show Ra fluxes almost as high as the tidal cycle data require and as the closed chambers inhibit physical turbulence, mixing due to turbulence of interstitial water is probably not the major transport mechanism of radium from the marsh sediments. In addition, a preliminary experiment indicates that a significant amount of water is not entering the chamber due to tidal pumping.

However, bioturbation and irrigation may indeed increase the flux of radium from the sediments by increasing the effective surface area of the marsh and by physically moving water of higher radium activity to the overlying water. Fiddler crab burrows dot the sediment surface from the creek banks to the low *Spartina alterniflora*, *Salicornia* areas of the marsh and effectively increase the sediment surface area. Worms, fiddler crabs and other residents of the marsh sediments also rework the sediments, physically moving water containing high radium activity towards the surface of the marsh.

The activities of ^{224}Ra in the water at low tide (C_L = 3 d.p.m. l^{-1}) and high tide (C_H = 1 d.p.m. l^{-1}) and in the pore water at 5 cm depth (C_P = 12 d.p.m. l^{-1}) as well as the volume of water which flushes the marsh during one tidal cycle

$V_{in} = V_{out}$) constrain the volume of water which is mixed through the upper 5 cm of the sediment (V_{mix}) as follows:

$$V_{out}C_L = V_{in}C_H + V_{mix}C_P - V_{mix}C_H$$

Using the observed data $V_{mix} = 9 \times 10^9$ cm^3. Thus, the residence time of water in the upper 5 cm of sediment can be determined from the following equation

$$\tau = \frac{\text{porosity} \times \text{depth} \times \text{area}}{V_{mix}/12\text{ h}}$$

and is of the order of 2–3 days.

Our study indicates that salt marshes are important sources of radium isotopes to coastal waters. The short residence time of water in the top centimetres of the salt marsh sediments and the high flux of radium out of the sediments demonstrate that marshes are extremely active chemical systems able to respond to changing conditions on a time scale of days. These observations have important implications for our understanding of the cycling of nutrients, metals, carbon and pollutants in coastal systems.

Ultraviolet sensitivity in hyperpolarizing photoreceptors of the giant clam *Tridacna*

Lon A. Wilkens*

Department of Neurobiology, Research School of Biological Sciences, Australian National University, Canberra City, ACT 2601, Australia

The giant clam *Tridacna* is a common shallow-water inhabitant of Indo-Pacific coral reefs[1]. These animals contain large populations of photosynthetic zooxanthellae in hypertrophied siphonal lobes which extend well beyond the edge of the shell for maximum exposure to light[2–4] (Fig. 1). Protection for these large fleshy lobes is visually mediated and consists of a partial siphon retraction and valve adduction, a behaviour which gives rise to a forceful, startling jet of seawater[5]. Numerous eyes (up to several thousand in large animals[6]) located along the margin of the siphon comprise a visual system which presumably mediates the defensive withdrawal reflex. Here we present the first report on the physiological properties of the visual system in *Tridacna*. Intracellular electrophysiological recordings have revealed two distinct types of retinal cells: both are hyperpolarized by light but only one generates axonal spikes. We also describe cells with differential colour sensitivity, including receptors that are sensitive to ultraviolet (UV) light. Ultraviolet sensitivity, although not previously reported in molluscs[7], may be an adaptation in *Tridacna* to the environmental requirements of a host for algal symbionts.

* Present address: Department of Biology, University of Missouri-St Louis, 8001 Natural Bridge Road, St Louis, Missouri 63121, USA.

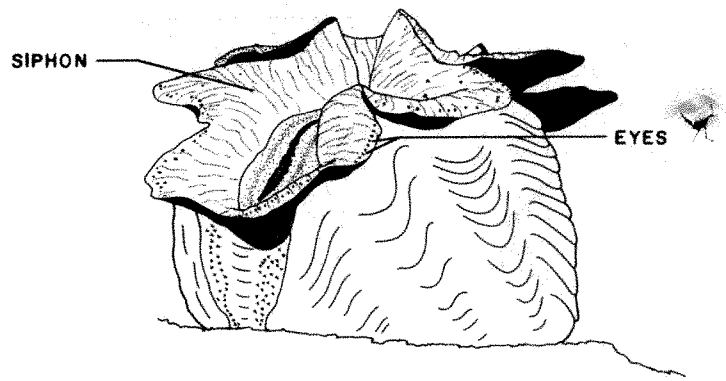

Fig. 1 *Tridacna maxima* L., drawn from a 35 mm colour slide projection (see cover) showing the posterior lobes of the siphon, the slit-like inhalant aperture and the right valve. The siphon lobes are fully extended, as they are in bright sunlight, with the eyes (bold dots) forming a line around the lateral margins. Shell length, 16.5 cm.

Tridacna were collected at Davies Reef in northern Queensland. The eyes are visible at the mantle surface as clear lens-like structures surrounded by a dense accumulation of pigmented zooxanthellae. Retinal cells line the back of the eye capsule and an optic nerve extends into the adjacent tissues[3,8]. In these experiments the epithelium was removed and the lens gently expressed to expose the retina. Glass micropipettes containing 3 M KCl were then lowered directly onto the retina for intracellular recording. Light from a xenon arc source was shone on the eye using a fibre optic light guide and was controlled by an electronic shutter in combination with neutral density and interference filters.

In recordings from over 100 light-sensitive cells, the receptor potentials were exclusively hyperpolarizing (Fig. 2). However, two distinct classes of cells exist: spiking (S) and non-spiking (NS). Of the cells encountered in these experiments, a slight majority were NS (52%), although both types were observed in most eyes. That the absence of spikes in NS cells is a physiological characteristic of these receptors, and not an artefact due to injury from electrode penetration, was established by the following observations: (1) injury discharges, which were occasionally observed in S cells, were never seen in NS cells; (2) S-cell spikes remain for the duration of stable penetrations in most instances, occasionally lasting for 30–60 min; and (3) additional physiological characteristics invariantly correspond with the presence or absence of spikes. For example, NS cells have low resting membrane potentials in the dark (-14.4 ± 6.7 mV, ±s.d.) and large receptor potential amplitudes (Fig. 2*a*); responses greater than 100 mV have been observed in fully dark-adapted preparations, but these potentials are readily attenuated by successive light stimuli and adapt to an intermediate level of polarization (-37.8 ± 12.7 mV) under steady illumination at high intensities (Fig. 2*b*). In contrast, S cells have a larger resting membrane potential (-43.8 ± 6.6 mV) than NS cells, but the receptor potential amplitude is smaller (14.0 ± 5.2 mV) and not affected by light or dark adaptation. The difference in adaptation sensitivity is most striking in response to light flashes of long duration where, by comparison with NS cells, the S cell maintains a steady level of membrane hyperpolarization; in some instances there is a subsequent gradual depolarization by a few millivolts (for example, 3–4 mV in Fig. 2*c*). However, there was very little difference in response latency between S and NS cells.

As with the cell represented in Fig. 2*c*, many S cells are spontaneously active in the dark and the spikes, 3–8 mV in amplitude, are inhibited by light. In response to dimming, bursts of spikes (60–80 Hz; 0.5–2.0 s) are generated on the depolarizing phase of the receptor potential, with the frequency and duration of the burst being increased by longer periods of light exposure. Thus, S cells are sensitive to light adaptation, although not directly in terms of the receptor potential waveform.

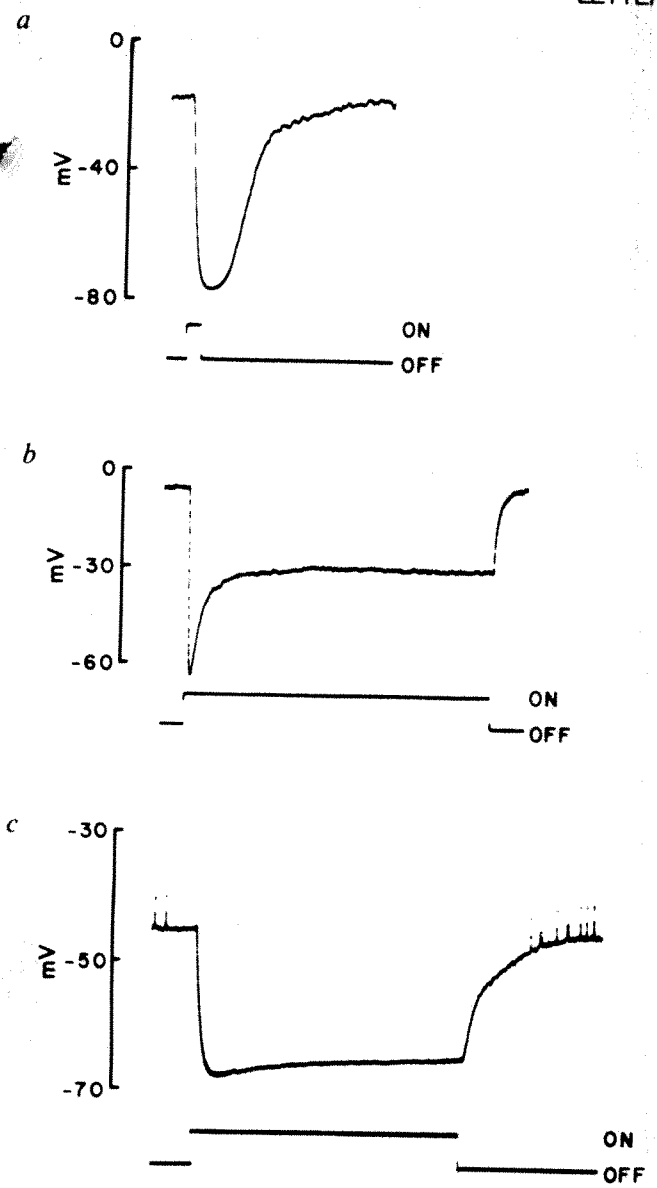

Fig. 2 Hyperpolarizing receptor potentials recorded intracellularly from *Tridacna* retinal cells. Receptor potentials from non-spiking (NS) photoreceptors in response to *a*, a brief light flash (250 ms); *b*, a light-adapting stimulus (2 min). NS receptors have a low resting potential in the dark and adapt rapidly to light. *c*, Receptor potential from a spiking (S) photoreceptor in response to an extended period of light stimulation (1.5 min). S receptors have higher resting potentials than NS cells but the light-mediated hyperpolarization does not adapt to light. Spikes occur spontaneously and in bursts on the depolarizing phase at light-off.

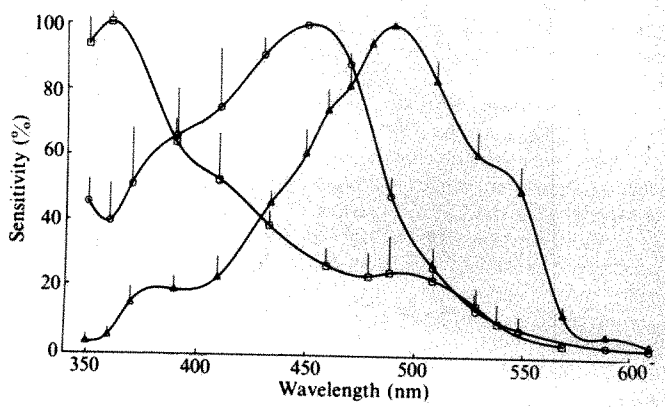

Fig. 3 Spectral sensitivity of *Tridacna* photoreceptors. Relative sensitivity, as measured by the amplitude of the hyperpolarizing receptor potential, plotted against wavelength. Individual photoreceptor sensitivity curves fall into three groups and the results shown are the means (±1 s.e.) for cells in each category with curve-smoothing based on a spline function: $\lambda_{max} = 490$ nm, $n = 7$ (Δ); $\lambda_{max} = 540$ nm, $n = 2$ (○); $\lambda_{max} = 360$ nm, $n = 4$ (□). Constant intensity light flashes, of 100–200 ms duration in different experiments, were given at 15-s intervals—stimulus parameters determined not to be light adapting.

To test the colour sensitivity of *Tridacna* photoreceptors, receptor potential amplitudes were measured in response to monochromatic light flashes from 350 to 610 nm. Data were used only from experiments in which stable responses were obtained for V–log I test sequences preceding and following the spectral test series. Surprisingly, we found individual receptors with sensitivity peaks at three specific wavelengths (Fig. 3): of 13 cells meeting the criteria, seven were green-sensitive ($\lambda_{max} = 490$ nm), two were blue-sensitive ($\lambda_{max} = 450$ nm), and four were sensitive to UV light ($\lambda_{max} = 360$ nm). All of the NS cells in this group were sensitive to green light, whereas S cells were represented in each category including one green- and all of the blue- and UV-sensitive photoreceptors. Behavioural sensitivity to various colours of light was also tested. Under a low level of white background illumination, siphon retractions were recorded in response to 3-s interruptions of adapting light at selected wavelengths. The siphon responded to conditioning light over the range of colours used in the physiological studies, but the threshold intensity for UV light (350 nm) was approximately four times greater than that for green light (490 nm).

Tridacna photoreceptors exhibit several interesting physiological features. In contrast to the scallop whose eyes contain both depolarizing (proximal) and hyperpolarizing (distal) photoreceptors[9], each directly initiating axon spikes, *Tridacna* has two types of hyperpolarizing receptor but only one has the ability to generate spikes. It is possible that *Tridacna* NS cells may not be photoreceptors, but instead are glial cells passively responding to adjacent receptors. This explanation is unlikely as (1) other cells (glial candidates) with no response of any kind are frequently penetrated, (2) response latencies are equivalent for both receptor cells, and (3) Lucifer yellow injections of both S and NS cells show axons projecting from the cell soma (unpublished results). Non-spiking photoreceptors, in addition to the vertebrate rods and cones, are now well known in arthropods (for example, barnacles[10]) but they have not previously been reported in molluscs and their physiological role is unknown. The S cell, on the other hand, is the physiological equivalent of the scallop distal photoreceptor: common features include a hyperpolarizing receptor potential which does not adapt to light[9], and an 'off-response' burst of spikes, the intensity of which is directly related to preceding light conditions[11]. Spike output therefore appears to correspond to an accumulating excitatory component of the light response which is masked by a separate 'primary' light-inhibiting effect expressed by the hyperpolarizing receptor potential. It has been suggested[12] that primary light inhibition may be characteristic of bivalve visual systems where the predominant light response in a variety of pallial photoreceptor systems is to dimming, that is, to a shadow[12–14], and where behaviourally relevant shadow reflexes are the norm[12,15].

Of even greater interest is the existence of receptors sensitive to short wavelengths of light, specifically to UV. In previous studies encompassing each of the three major molluscan classes[7,12,13], the maximum sensitivity for rhodopsin-like photopigments was typically around 490 nm, a value corresponding with that of the NS cells in *Tridacna*. UV light receptors represent a significant departure from this pattern, and it is doubtful that the electroretinograph or compound nerve-recording techniques used in several of the previous studies would have obscured the presence of UV receptors. *Tridacna* is a unique mollusc in several

respects, and recognition of these features can assist in the formulation of hypotheses to account for UV sensitivity in this genus.

Of the previous molluscs tested, including several intertidal bivalves, all are able to limit their exposure to UV light by means of protective shells or cryptic locomotor behaviour, and/or they occupy temperate neritic waters where this spectral component is rapidly absorbed at the surface. In contrast, *Tridacna* occurs in a shallow-water tropical habitat, including reef flats that are partially exposed at low tide, where turbidity is low and UV penetration maximal[16,17]. In these regions UV irradiation is known to be a major limiting factor in the distribution of marine invertebrates[18]. Despite this fact, *Tridacna* intentionally exposes its siphonal lobes to intense light and furthermore does not normally withdraw completely into its shell unless provoked repeatedly. UV light receptors may somehow be involved in this positive siphonal phototropism, which in turn may be correlated with the fact that the algal symbionts use a broad spectrum of light (300–700 nm) for photosynthesis[19]. Alternatively, the UV receptors may be functional components of the defensive withdrawal reflex, a behavioural possibility established in the present experiments and further supported by the fact that UV sensitivity is represented in the class of receptors that are physiologically adapted to respond directly to shadows. Whatever the precise role, it seems that *Tridacna* has adapted a range of spectral sensitivities within its population of retinal cells to match the colours present in its environment.

This work was supported in part by a grant from the Whitehall Foundation. The assistance of the Australian Institute of Marine Science, Townsville, in providing laboratory facilities at the Institute and on board the RV *Lady Basten* and RV *Sirius* is greatly appreciated. We thank Langdon Quetin and Martin Jones for shipping animals, and Simon Laughlin for computer processing of spectral data. This paper represents a contribution from the Tallahassee, Sopchoppy and Gulf Coast Marine Biological Association (no. 209).

Threshold channels—a novel type of sodium channel in squid giant axon

Wm. F. Gilly

Hopkins Marine Station of Stanford University, Department of Biological Sciences, Pacific Grove, California 93950, USA

Clay M. Armstrong

Department of Physiology, University of Pennsylvania Medical School, Philadelphia, Pennsylvania 19104, USA

Sodium channels in nerve and muscle cells are functionally similar across wide phylogenetic boundaries[1] and are usually thought to represent a single, homogeneous population that initiates the action potential at threshold and unerringly transmits it along the surface membrane. In marked contrast, many cell types are known to have several distinct potassium permeability systems[2,3]. Distinguishable populations of Na channels have been reported in a few cell types, however, including denervated skeletal muscle[4], embryonic cardiac muscle[5], Purkinje cell somata[6] and non-myelinated axons at low temperature[7]. We report here that in squid giant axon, in standard experimental conditions, there are two functionally distinct populations of Na channels. The newly discovered population accounts for only a few per cent of the total Na permeability. The channels are selectively activated by small depolarizations and have very slow closing kinetics. Because these channels activate at voltages near the resting potential and tend to stay open for long times, they must dominate behaviour of the axon membrane in the threshold region for action potential initiation.

Experiments on *Loligo pealei* were performed at the Marine Biological Laboratory, Woods Hole, Massachusetts. Cleaned axons were internally perfused and voltage-clamped as described previously[8,9]. Improvements in the electronic apparatus were important to this study in allowing the resolution of very small ionic currents ($<1\ \mu A\ cm^{-2}$). For measuring Na current (I_{Na}) plus gating current (I_g), the external solution contained (in mM): 60 (or 120) NaCl, 50 $CaCl_2$ and 352 (or 452) Tris *p*H 7.0 (Sigma) (60 or 120 Na; see figure legends). Gating currents were recorded by replacing all Na with Tris *p*H 7.0 and adding 200 nM tetrodotoxin (TTX). I_{Na} records were subsequently generated by subtraction. The internal solution was K-free; both tetramethylammonium (TMA) and Cs were used as K substitutes with similar results (150 mM as glutamate salt and 50 mM as fluoride salt). Internal solutions also contained (in mM): 10 Tris *p*H 7.0 and 560 sucrose. Pronase (Sigma type XIV) was internally applied (0.5 mg ml^{-1}) in some experiments to destroy inactivation as indicated below. Temperature was 8 °C, holding potential −80 mV, and we compensated for 2–3 $\Omega\ cm^2$ of series resistance. Particular care was taken to test for contamination of I_{Na} by end effects; tests included applying TTX to the axon ends in the air gaps, reducing the external Na concentration to as low as 30 mM, and comparing currents measured from different regions of the same axon. The phenomena described below were not affected by these control procedures.

The new channels that are activated in the threshold region were first recognized by their unusually slow closing kinetics. In Fig. 1*a*, the trace obtained in 120 mM Na shows the activation of $I_{Na} + I_g$ during a pulse to −50 mV as Na channels open, and the decay of current when the voltage is returned to −80 mV as the channels close. The tail current at −80 mV clearly has a fast and a slow phase of decay. The same procedure in the absence of external Na (0 Na, no TTX) shows an outward I_g transient at the beginning of the pulse which has the same initial amplitude as in 120 mM Na. After the return to −80 mV, I_g is inward and fast. The slow component is not seen in 0 Na and thus can be identified as Na current. Other experiments also showed it to be TTX-sensitive. Subtraction of the traces in Fig. 1*a* yields I_{Na} (Fig. 1*b*), and two components of tail current differing in decay rate by roughly an order of magnitude are still evident. Similar results were seen in every axon (total of 17) in which this phenomenon was examined over a 3-yr period.

Fast and slow components of I_{Na} decay accompany a variety of activating pulse amplitudes and durations. Following large pulses, however, the slow component constitutes a tiny fraction of the total current, and perhaps for this reason has been previously overlooked. Figure 2*a* illustrates the decay of I_{Na} in a Pronase-treated axon after a small pulse (−40 mV, 15 ms) and after a large pulse activating nearly all of the Na conductance (+40 mV, 3 ms). The two traces have very different initial ampli-

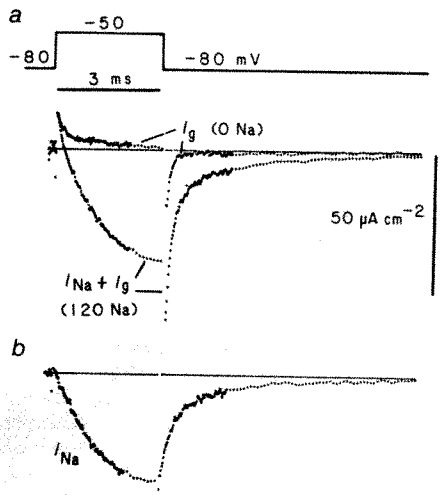

Fig. 1 Time course of Na current (I_{Na}) and gating current (I_g) activation at −50 mV, and deactivation at −80 mV. *a*, $I_{Na} + I_g$ (120 mM external Na) accompanying a 3-ms pulse is compared with I_g alone (0 Na). *b*, I_{Na} generated by subtraction of the traces in *a*. I_{Na} has clear fast and slow components of deactivation. JN243G; 120 mM Na, 200 mM TMA; Pronase-treated.

tudes, but they converge between 1.5 and 2 ms and decay slowly thereafter. Ignoring the small slow component, the +40 mV tail can be fitted well by a single exponential with time constant 150 μs. The −40 mV trace can be fitted with the sum of two exponentials having time constants of 180 μs and 1.9 ms—this disparity in values indicates distinct fast and slow phases of I_{Na} decay.

Figure 2*b* shows tail currents for a series of activating voltages. Traces for the three largest pulses (−45, −40 and +40 mV) have been truncated to allow the slow tail current to be plotted at high gain. Durations of the pulses ensured that the amplitude of the slow component was maximal in each case. The slow component increases with activating voltage up to ~−40 mV, where it reaches its maximum size. Its amplitude after the +40 mV step is the same. Activation kinetics of the channels underlying the slow tails are voltage-dependent and become faster at more positive voltages. Thus, 3 ms at +40 mV is as effective as 10–15 ms at −40 mV.

Each trace in Fig. 2*b* has both a fast and slow decay phase, but the two components differ greatly in relative magnitude, depending on the activating voltage. For the −55 mV pulse, the fast and slow components are roughly equal in size. Above −40 mV, only the fast component continues to grow, and it is much larger than the slow one after a step to +40 mV (Fig. 2*a*).

These results are very difficult to explain on the basis of a single, homogeneous population of Na channels having multiple conducting states. Instead, they support the existence of a small group of Na channels that are activated over a relatively negative voltage range and have very slow closing kinetics. The fast component of Na tail current reflects activation of a much larger group of 'normal' channels that have fast closing kinetics and activate at more positive voltages. Figure 3 shows the fraction of open channels plotted as a function of membrane potential for both populations. Near the resting potential the percentage of slowly closing channels activated (circles) is far larger than the activated fraction of normal channels. Small depolarizations to the region of action potential threshold (that is, −60 to −55 mV) would selectively activate the new channels. Although the total permeability contributed by this population is small (~3% of the total in Fig. 3), the channels can carry enough current to depolarize the membrane far beyond threshold for an action potential. Our results suggest that at least half of the channels that are open at threshold (for example, −55 mV in Fig. 2*b*) are of the new type. Thus, we label them 'threshold' channels, as they must dominate behaviour in the threshold region.

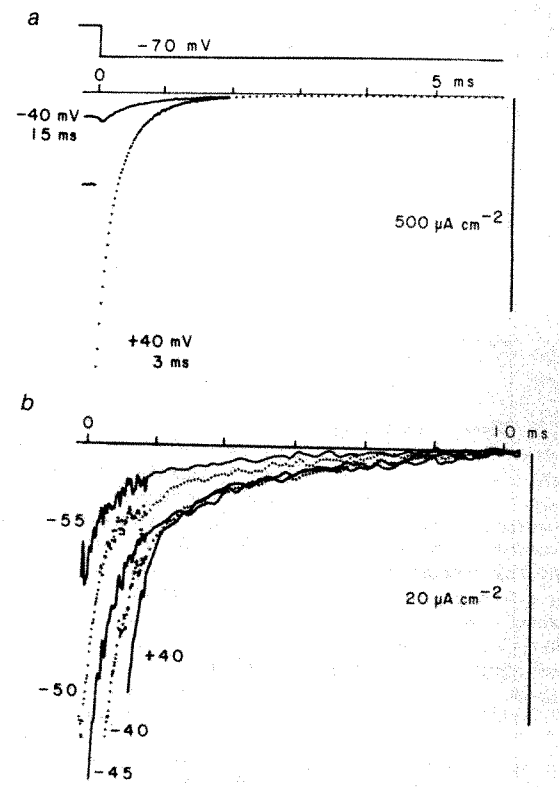

Fig. 2 Behaviour of fast and slow components of Na tail currents as a function of activating voltage. *a*, Currents recorded at −70 mV following a small (to −40 mV, for 15 ms) or large (+40 mV, 3 ms) depolarization. The axon was Pronase-treated. The initial amplitude of the tail currents is proportional to the number of channels opened. At −40 mV the number of open channels is ~10% of that at +40 mV. Although initial amplitudes are very different, the two traces converge between 1.5 and 2 ms. *b*, Tail currents for a series of activating voltages showing that the amplitude of the slow component saturates at ~−40 mV. Early portions of the traces for the three largest pulses are truncated; initial amplitudes were (in μA cm^{-2}) 40.5 (−45 mV), 69 (−40 mV) and 599 (+40 mV). Pulse durations were 15 ms, except for 3 ms at +40 mV. JN223H; 120 mM Na, 200 mM Cs.

The points for threshold channels in Fig. 3 can be adequately fitted by a two-state model having one open and one closed state. The solid curve assumes that the equilibrium constant for the transition from open to closed varies exponentially with voltage, changing e-fold in 4.5 mV. In terms of a Hodgkin–Huxley-like model[10] this corresponds to control of the channel by a single gating particle having 5.5 electronic charges associated with it. The normal channels require a multi-state model (several gating particles in Hodgkin–Huxley terms), making the conductance–voltage relation much less steep near its midpoint. The limiting steepness at very negative voltages may be similar to that for the threshold channels. Na conductance in Pronase-treated axons has been reported to change e-fold in 4.2 mV[11] to 5.3 mV[12]. These values may require reevaluation, however, because of the contribution made by threshold channels.

Sodium channels are normally inactivated during a maintained depolarization, and threshold channels share this property. Figure 4 shows three I_{Na} tails following the specified activating pulses from an axon with its inactivation mechanism intact, that is, not Pronase-treated. After 0.3 ms at +40 mV or 3 ms at −40 mV, inactivation has not progressed very far, and the slow components in those traces are identical. Both are about as large as can be recorded in a fibre with the inactivation mechanism functioning. Inactivation proceeds rapidly at +40 mV, however, and after 3 ms the slow component is virtually absent. Initial tail amplitude was also greatly reduced. Thus, both normal and threshold channels are inactivated with a rapid time course at +40 mV.

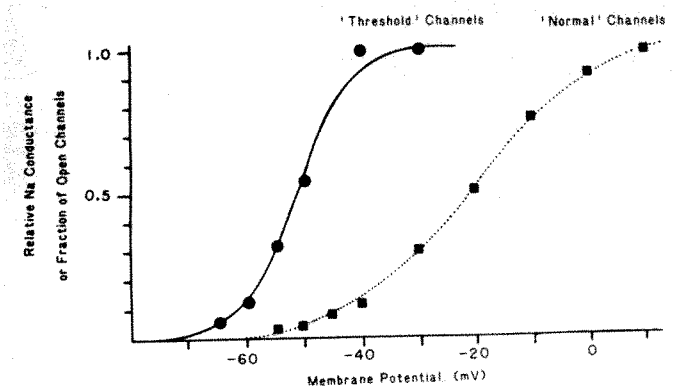

Fig. 3 Steady-state voltage dependence of Na conductance for 'threshold' versus 'normal' channels obtained in a Pronase-treated axon. Maximum conductance was 0.13 mS cm^{-2} for threshold channels as opposed to 4.3 mS cm^{-2} for normal channels, all measured in 60 mM Na. Conductance of normal channels (■) was measured at −80 mV as $\Delta I_{Na}/\Delta V$, 30 μs after termination of an activating depolarization to the indicated membrane potential[11]. The dotted curve was drawn by eye. Conductance of threshold channels (●) was estimated from tail current amplitude (at −80 mV) 2.5 ms after termination of the activating pulse. The solid curve represents a Boltzman distribution between open and closed channels such that the fraction of open channels = $e^{(V-V_{1/2})Z/25}/[1+e^{(V-V_{1/2})Z/25}]$ where V is membrane voltage (in mV), $V_{1/2} = -51$ mV, and $Z = 5.5$ electronic charges moving entirely across the membrane's electric field. Same axon as in Fig. 1; 60 mM Na, 200 mM TMA.

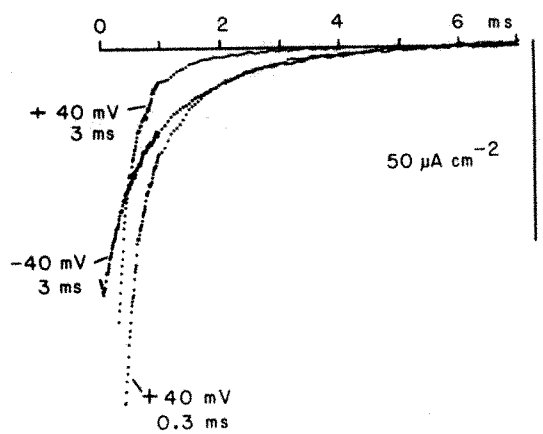

Fig. 4 Tail currents from a non-Pronase-treated axon with its inactivation mechanism intact. The slow component of current decay is identical following both the small pulse (−40 mV, 3 ms) and the brief, large pulse (+40 mV, 0.3 ms), neither of which produced significant inactivation. The slow component is nearly eliminated following the longer pulse to +40 mV (3 ms) which also produced substantial inactivation of the fast component. The +40 mV traces are truncated; initial amplitudes were 670 μA cm^{-2} (0.3 ms) and 320 μA cm^{-2} (3 ms). JN203G; 120 mM Na, 200 mM TMA.

Sodium channels similar to threshold channels have not been described for other preparations in studies using either conventional or single-channel techniques. Single-channel measurements should be a sensitive way of independently discerning these unusual channels. To keep the number of open Na channels conveniently small, these measurements are often made with small depolarizations, which would selectively activate threshold channels, at least in squid axon. The slow closing kinetics we report here as being diagnostic of these channels would be manifest in single-channel data as events with unusually long open times that were particularly evident between −70 and −40 mV. Unfortunately, single-channel data are not available for squid axon.

Thus, our results reveal the existence of a small but distinct second population of Na channels, the threshold channels. Compared with the normal channels, the threshold channels activate at relatively negative voltages and close very slowly once opened. Triggering the action potential is the probable function of the threshold channels. The normal Na channels, activating over a more positive voltage range, supply the large current required for rapid conduction. One advantage in this division of labour is noise reduction: there are fewer channels operating in the threshold region, and therefore less chance of a spurious action potential being triggered by the random, spontaneous opening of enough channels to reach threshold. The overall importance of threshold-type channels as described here is unknown. They must be important in squid axon for phenomena like repetitive firing. If similar channels exist in different regions of individual neurones, for example, dendrites or axon hillocks, they should have profound effects on determining the site of impulse initiation[6,13,14], and if they exist in autorhythmic cells, would greatly influence pacemaking or bursting behaviour.

Current generated by backward-running electrogenic Na pump in squid giant axons

Paul De Weer & R. F. Rakowski

Department of Physiology and Biophysics, Washington University School of Medicine, St Louis, Missouri 63110, USA

The sodium pump of animal cells is electrogenic[1,2], that is, it normally exports more sodium ions than it imports potassium ions[3]. In the squid giant axon, the resulting net outward electric current[4] has a density of a few μA cm^{-2}, and contributes 1–2 mV to the resting membrane potential[5,6]. The pump is driven by the free energy of hydrolysis of ATP, and in some instances[7–10] it has been possible to run the pump backwards and synthesize ATP by lowering the [ATP]/[ADP]·[P_i] ratio and steepening the transmembrane Na^+ and K^+ gradients. Here we have examined the question of whether a backward-running sodium pump conserves its $Na^+/K^+ > 1$ stoichiometry. We demonstrate reversal of the sodium pump of squid giant axon, and find that backward pumping indeed produces a net inward electric current. This current is voltage-sensitive. Our observations have mechanistic implications for models of the sodium pump.

It is generally accepted that the sodium pump normally operates with Na/K > 1 stoichiometry. What is less clear is whether this stoichiometry is fixed or variable and dependent on conditions such as steepness of the ion gradients, membrane potential and available free energy of ATP hydrolysis[2]. One extreme situation is a reversal of the pump's operation, resulting in synthesis of ATP. If the pump's normal stoichiometry (say, $3Na^+/2K^+$) were conserved, one should find an inward pump current. We have tested this hypothesis by forcing the sodium pump of squid giant axon to run backward, and simultaneously

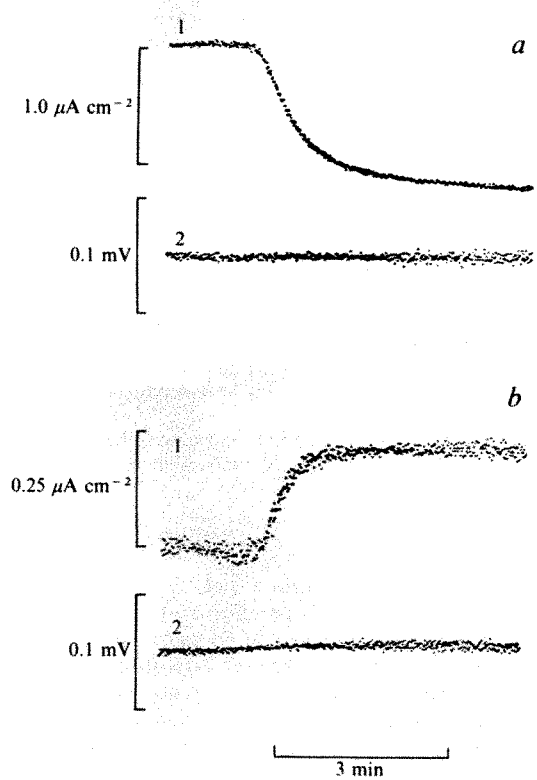

Fig. 1 Electrogenic pump measurements in squid giant axons. *a*, Axon bathed in artificial seawater containing (in mM) 425 NaCl, 10 KCl, 10 $CaCl_2$, 25 $MgCl_2$, 25 $MgSO_4$, 5 Tris-HEPES *p*H ~7.7 and 2×10^{-7} M tetrodotoxin, and internally dialysed with a solution containing (in mM) 50 NaCl, 200 K-glutamate, 100 K-HEPES *p*H 7.4, 250 glycine, 10 $MgCl_2$, 1 EGTA, 5 ATP, 3 phosphoarginine (PA) and 3 phosphoenolpyruvate (PEP), the latter four as potassium salts. 1, Holding current. About 1.3 min into the record, 10^{-5} M H_2DTG was added to the seawater. The resulting change in holding current density was -1.1 μA cm^{-2}. 2, Membrane potential. Holding potential varied less than 20 μV during the response. Temperature 17 °C. *b*, Axon bathed in K^+-free artificial seawater (NaCl replaced KCl). Internal fluid was Na^+-free (equimolar replacement with *N*-methyl-D-glucamine) and contained no ATP, PA or PEP, but 5 mM each of ADP and P_i, as well as 1 mM diadenosine pentaphosphate (an inhibitor of adenylate kinase) and 50 μM atractyloside (an inhibitor of mitochondrial ATP/ADP transfer). 1, Holding current; 2, membrane potential. The holding current change on addition of 10^{-5} M H_2DTG to the seawater was 0.23 μA cm^{-2}. The more rapid action of H_2DTG (compared with the forward case) can be explained by the absence of potassium from the seawater. Temperature 17 °C.

Methods: The axons were mounted in a Lucite chamber 9 × 3 × 3 mm, one side of which was a blackened platinum plate; the chamber was sealed at both ends with petroleum jelly. Artificial seawater superfused the axon at about 1 ml min^{-1}. A cellulose acetate capillary (diameter 140 μm; porous in its middle) was threaded through the axon, and a conventional 'piggy-back' voltage-clamp electrode assembly, made of a 100–120 μm, 0.5 M KCl-filled glass microelectrode with a 75 μm blackened platinum wire glued to it, was placed alongside the capillary and centred in the chamber. The current-passing platinum wire protruded 1–2 mm beyond the end of the chamber. The flow rate of the internal dialysis fluid was ~1 μl min^{-1}. A glass capillary electrode, similar to the internal one, was dipped into the chamber. Both electrodes were connected, via matched calomel electrodes, to a 'slow' (time constant 0.1 s) and very stable voltage-clamp device. When a steady perfusion regime had been achieved, the axon was voltage-clamped, usually at −60 mV or at its resting potential. Both holding potential and clamp current were digitized, collected and stored by a microcomputer. Ten data points were sampled and averaged every 825 ms for each point displayed in the figure. Outward holding current is displayed upward. To measure the magnitude of the change in holding current, straight lines were fitted by least-squares analysis to the linear portions of the record before and after the transient, and the vertical distance between the two lines was evaluated at the midpoint of the transient.

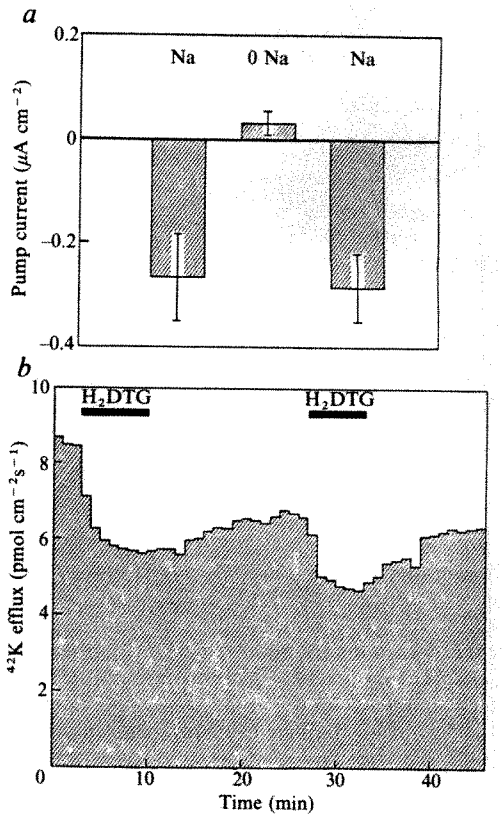

Fig. 2 Electrogenic current and potassium efflux during reverse pumping. *a*, Average (±s.e.m.) pump current in the inward direction (combined results of six tests on five axons) before (-0.27 ± 0.08), during ($+0.03 \pm 0.02$) and after (-0.29 ± 0.06 μA cm^{-2}) removal of sodium from the external seawater (replacement, *N*-methyl-D-glucamine). Bars show s.e.m. Sodium-free internal fluid throughout, as in Fig. 1*b*. Temperature 17 °C. *b*, Inhibition of ^{42}K efflux by H_2DTG. The effect of adding 10^{-5} M H_2DTG on ^{42}K efflux is shown for an axon held at −60 mV. Solutions as in Fig. 1*b*. The time during which H_2DTG was present in the external solution is indicated by the horizontal bar. A second application and washout of H_2DTG is also shown. The magnitude of the first response was 3.4 pmol cm^{-2} s^{-1}, and of the second, 2.0 pmol cm^{-2} s^{-1}. Temperature, 17 °C.

measuring cardiotonic steroid-sensitive membrane current under voltage-clamp control.

Giant axons from the hindmost stellar nerve of the squid, *Loligo pealei*, were cleaned, mounted in a horizontal chamber and superfused with artificial seawater at either 17 or 24 °C. The axons' intracellular composition was controlled by internal dialysis using a porous capillary[11]. Membrane potential was controlled by a slow and very stable voltage-clamp apparatus (R.F.R. *et al.*, in preparation). The principle of the pump current measurement[12] is as follows: sudden exposure of the voltage-clamped cell to a cardiotonic steroid (ouabain or the more reversible[4] dihydrodigitoxigenin, H_2DTG) will cause a change in clamp holding current exactly equivalent to the current generated previously by the sodium pump, provided that the steroid does not alter the passive membrane conductance. This requirement has been tested and is met (P. De W. *et al.*, in preparation).

Figure 1*a* shows a representative forward pump-clamp experiment, performed on an axon superfused with 425 mM Na^+, 10 mM K^+ seawater and internally dialysed with a solution containing 50 mM Na^+, 290 mM K^+ and 5 mM ATP. Addition of 10^{-5} M H_2DTG to the seawater produced an inward change in holding current (1.1 μA cm^{-2}). (For comparison, typical peak sodium channel membrane current densities in squid axon are ~2–5 mA cm^{-2}, and peak gating current densities, ~30 μA cm^{-2}.) The axon in Fig. 1*b*, on the other hand, was bathed in K^+-free seawater and internally dialysed with Na^+-

Table 1 Cardiotonic steroid-sensitive currents and fluxes in squid axons measured in conditions designed to produce reverse sodium pumping

Measurement	Mean ± s.e.m.	Membrane potential (mV)	No. of expts	No. of axons	Remarks*
Current ($\mu A\ cm^{-2}$)	-0.332 ± 0.037	-65.8 ± 1.7	19	9	17 °C; 1982
	-0.145 ± 0.014	-58.2 ± 1.5	32	12	17 °C; 1983
	-0.316 ± 0.058	-53.1 ± 1.5	11	4	24 °C; 1983
Sodium influx (pmol $cm^{-2}\ s^{-1}$)	6.38 ± 0.70	-55.5 ± 9.5	2	2	17 °C; 1982/83
Potassium efflux (pmol $cm^{-2}\ s^{-1}$)	2.50 ± 0.25	-57.4 ± 1.2	12	6	17 °C; 1983

All current measurements were carried out as described in Fig. 1 legend. The seawater was K^+-free as described for Fig. 1*b*; the cardiotonic steroid was either 10^{-5} M H_2DTG (reversible) or 10^{-5} M ouabain (irreversible). The internal dialysis fluid composition was as in Fig. 1*b*, except that [ADP] and [P_i] varied between 1 and 5 mM, with no obvious repercussions, and diadenosine pentaphosphate levels varied between 0.25 and 1 mM. Flux measurements were made in identical conditions except that either the seawater contained ^{22}Na or the internal dialysis fluid contained ^{42}K. Corresponding dialysis fluid or superfusate samples were collected and counted. Most of the ^{42}K experiments were conducted in the presence of 1 mM 3,4-diaminopyridine, which blocks potassium channels[19].

* For unknown reasons, perhaps related to ocean temperatures or other environmental factors, the 1982 animals appeared to have higher reverse sodium pump activity than the 1983 specimens. The forward pumping rate was also higher in the 1982 animals. A comparable year-to-year variation has previously been seen in the case of Mg^{2+} extrusion by these cells[20].

free fluid containing 5 mM ADP, 5 mM P_i and no ATP (ATP formation was blocked by diadenosine pentaphosphate and atractyloside). Here H_2DTG caused an outward change in holding current (0.23 $\mu A\ cm^{-2}$), signifying the disappearance of an inward pump current. Table 1, summarizing 60 reverse pump current measurements obtained on 30 axons, suggests a considerable temperature coefficient for reverse pumping ($Q_{10} \approx 3$). The presumption that Fig. 1*b* truly represents inhibition of a reverse electrogenic sodium pump (and not of, say, a forward pump with $K^+ > Na^+$ stoichiometry) was corroborated in three ways. First, a ouabain-sensitive sodium influx was seen in axons dialysed with Na^+-free fluid containing ADP and P_i (Table 1). Pump-mediated Na^+ influx into high-ADP cells is well known, but only as part of electroneutral $Na^+:Na^+$ exchange[4,12,13], which obviously requires intracellular Na^+. Second, the putative inward pump current is abolished by removal of Na^+ from the seawater (Fig. 2*a*). Third, we measured a cardiotonic steroid-sensitive ^{42}K efflux (Table 1, Fig. 2*b*) into K^+-free seawater, a condition which precludes $K^+:K^+$ exchange, a known mode of operation of the sodium pump[14,15]. (In unclamped axons engaged in forward pumping, ouabain causes ^{42}K efflux to increase through activation of K^+ channels following the depolarization which results from inhibition of the electrogenic sodium pump[6]). Simultaneous ^{42}K efflux and inward pump current measurements were made in 11 instances on 7 axons. The average (K^+ flux)/(net current) ratio was 2.7 ± 0.5, or one elementary charge carried in for every 2–3 K^+ ions pumped out. This suggests a Na^+/K^+ stoichiometry of 3/2 or 4/3.

A remarkable feature emerges when reverse electrogenic pump current is plotted against membrane potential (Fig. 3). In five cases from four axons, pump current measurements at a given potential were combined with measurements at another potential, and without exception, revealed a strong voltage dependence. Interestingly, the voltage dependence represents a negative pump conductance: contrary to simple thermodynamic expectation, the inward current decreases as the cell is made more negative. This may mean either that the pump operates in series with a voltage-sensitive gate[16] or that a rate-limiting kinetic step in the pump cycle is inhibited by negative membrane potentials[17,18].

We thank the Director, Marine Biological Laboratory, Woods Hole, for facilities put at our disposal, Dr D. C. Gadsby for help with some of the experiments, Drs L. Reuss and C. M. Rovainen for critical comments, and S. Eads and L. Larkin for secretarial assistance. This work was supported by NIH grants NS 11223 and NS19393.

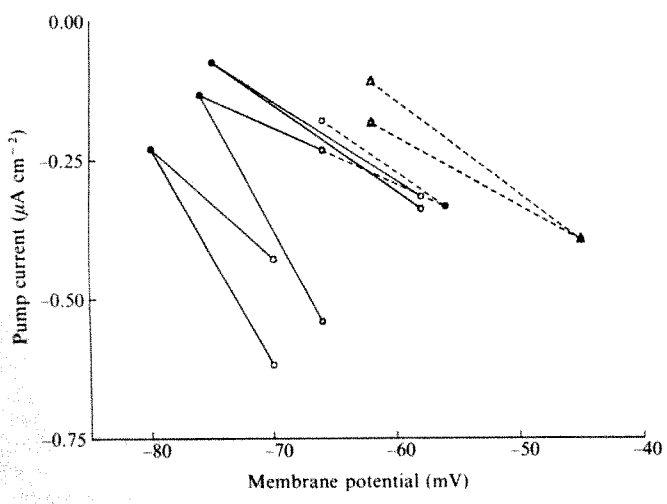

Fig. 3 Relationship between reverse pump current and membrane potential. Measurements were made as described in Fig. 1 legend. All axons were exposed to K-free seawater and perfused as described for Fig. 1*b*. Circles, 1982 data; triangles, 1983 data. The solid and dashed lines connect sets of bracketing (open symbols) and bracketed (filled symbols) measurements. Solid lines, bracketed test at hyperpolarized potential; dashed lines, bracketed test at depolarized potential. At each control voltage 10^{-5} M H_2DTG was applied, then washed out; the holding potential was changed to the test voltage during the recovery, and the axon re-exposed to H_2DTG at the test voltage; finally, during recovery from the second H_2DTG application the holding potential was changed back to the original control voltage, and the axon was exposed to H_2DTG for the third time. Temperature, 17 °C.

Mechanism of ion permeation through calcium channels

Peter Hess & Richard W. Tsien

Department of Physiology, Yale University School of Medicine, New Haven, Connecticut 06510, USA

Calcium channels carry out vital functions in a wide variety of excitable cells[1-4] but they also face special challenges. In the medium outside the channel, Ca^{2+} ions are vastly outnumbered by other ions. Thus, the calcium channel must be extremely selective if it is to allow Ca^{2+} influx rather than a general cation influx. In fact, calcium channels show a much greater selectivity for Ca^{2+} than sodium channels do for Na^+ (refs 5–9) despite the high flux that open Ca channels can support[3,4]. Relatively little is known about the mechanism of ion permeation through Ca channels. Earlier models assumed ion independence[5] or single-ion occupancy[10–16]. Here we present evidence for a novel hypothesis of ion movement through Ca channels, based on measurements of Ca channel activity at the level of single cells or single channels. Our results indicate that under physiological conditions, the channel is occupied almost continually by one or more Ca^{2+} ions which, by electrostatic repulsion, guard the channel against permeation by other ions. On the other hand, repulsion between Ca^{2+} ions allows high throughput rates and tends to prevent saturation with calcium.

Single ventricular cells were obtained from adult guinea pigs by enzymatic dissociation[17] and a suction pipette was used for voltage clamp and internal dialysis[18]. To minimize current flow through channels other than the Ca channel, internal and external solutions were kept Na^+- and K^+-free[6].

Figure 1*a* shows how the Ca current (I_{Ca}) varies with the bathing calcium concentration ($[Ca]_0$). The peak magnitude of I_{Ca} increases almost proportionally with $[Ca]_0$ over the range 1–10 mM, with increasing saturation as $[Ca]_0$ approaches 30 mM. This type of $[Ca]_0$ dependence is similar to that found for Ca channels in cardiac preparations and other excitable cells[1,2,11–16]. The saturation of I_{Ca} has been attributed to a single divalent cation-binding site within the Ca channel with a dissociation constant for Ca^{2+} (K_{mCa}) of ~10 mM (refs 11–16).

The interaction between Ca^{2+} and the channel can also be gauged by using Ca^{2+} to block the movement of other ions through the Ca channel. As Fig. 1*b* illustrates, addition of 0.6 mM Ca_0 to the bathing medium reduced the inward current in the presence of 10 mM Ba to less than half; in four cells the average decrease of current was to 41 ± 4% of that in the absence of Ca. The Ca-sensitivity of Ba currents is similar to the Ca-sensitivity of Sr action potentials in cardiac Purkinje fibres[10].

Figure 1*c* shows that Ca channel current carried by Na^+ (150 mM) is even more sensitive to $[Ca]_0$. Addition of only 1.3 μM Ca to the bathing medium lowered the Na influx through the channel to 33 ± 4% in three cells. This result is consistent with previous work in heart[19], snail neurones[14], skeletal muscle[20] and other excitable cells[13].

The very different estimates of K_{mCa} in Fig. 1*a–c* are inconsistent with competition for a single binding site. The discrepancy between various estimates of K_{mCa} would be even greater if allowance were made for changes in surface potential and binding of other ions. The estimate of K_{mCa} from Fig. 1*a* would be revised upward if allowance were made for effects of surface potential on the degree of Ca channel opening. On the other hand, estimates of K_{mCa} from Fig. 1*b* and *c* would have to be revised downward if binding of Ba or Na were taken into account.

The extreme $[Ca]_0$-sensitivity of Na movements through the Ca channels has been attributed to a high-affinity, regulatory Ca-binding site outside the channel, distinct from a relatively low-affinity Ca-binding site that lies within the channel and controls ion permeation[16]. Figure 2 shows another test of the one-site model which leads us to a different interpretation of

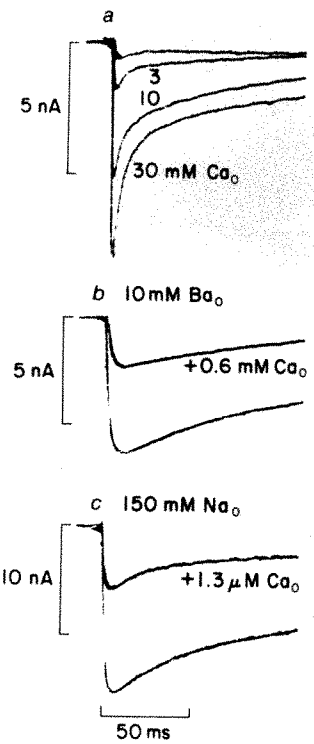

Fig. 1 Comparison of the ability of extracellular Ca to act as a charge carrier through the Ca channel (*a*) with its ability to block current through the channel carried by other ions (*b*, *c*). All records show net ionic currents after subtraction of linear leak and capacity currents determined from hyperpolarizing pulses. *a*, Currents recorded in consecutive runs with 1, 3, 10 and 30 mM $[Ca]_0$. Depolarizing pulses to +20 mV from a holding potential of −40 mV. External and internal solutions were Na^+- and K^+-free. Cell 165C. The internal solution contained (in mM): 75.5 Cs-aspartate, 75.5 Cs-phosphate, 10 Cs-EGTA, 6 HEPES (*p*H 7.4). The external solution contained (in mM): 85 Cs-aspartate, 146 sucrose, 2.8 $MgCl_2$, 5 glucose, 5 HEPES (*p*H 7.4) and $CaCl_2$ or $BaCl_2$ as noted in the figures. Series resistance compensation was used to offset the ohmic drop resulting from current flow through the tip of the suction pipette. Current signals were recorded and analysed on a PDP 11-03 laboratory computer. All experiments were done at room temperature (21 °C). *b*, Block of Ba current through Ca channels by addition of external Ca. Records shown were obtained with 10 mM $[Ba]_0$ in the absence and presence of 0.6 mM $[Ca]_0$. Voltage clamp pulse from −40 mV to +20 mV. Cell 180N. *c*, Block of Na current through Ca channels by addition of external Ca. The control record was obtained with the standard internal solution (see text) and the following external solution: 150 mM NaCl; 2 mM EGTA, 12.5 μM tetrodotoxin (TTX), 10 mM HEPES (*p*H 7.6). $[Ca]_0$ was then increased to 1.3 μM by changing to the following solution: 150 mM NaCl, 2 mM total HEDTA, 1 mM total Ca, 12.5 μM TTX, 10 mM HEPES (*p*H 7.6, apparent stability constant for CaHEDTA taken as $7.6 \times 10^5\ M^{-1}$). Pulse from −60 mV to +10 mV. Cell 207H.

the various effects of Ca^{2+}: *a* shows the behaviour expected for a simple one-site channel. In mixtures of Ca and Ba in which $[Ca]_0 + [Ba]_0$ is held constant at 10 mM, the total current can never be smaller than that in either 10 mM $[Ca]_0$ or $[Ba]_0$ alone; the total current must be a monotonic function of the mole fraction. This prediction was tested experimentally with recordings of whole-cell current in guinea pig ventricular myocytes (Fig. 2*b*). In contrast to the properties expected for a simple one-site channel, the measured current is not a monotonic function of the mole fraction, $[Ba]_0/([Ba]_0 + [Ca]_0)$, but goes through a clear minimum as 70% of the external Ca is replaced by Ba. Similar behaviour of currents in mixtures of permeant ions has been reported previously for gramicidin channels[21,22], K channels[23] and Cl channels[24,25]. Such 'anomalous mole fraction effects'[26] have been accounted for by models which include two (or more) ion-binding sites within the channel and repulsive

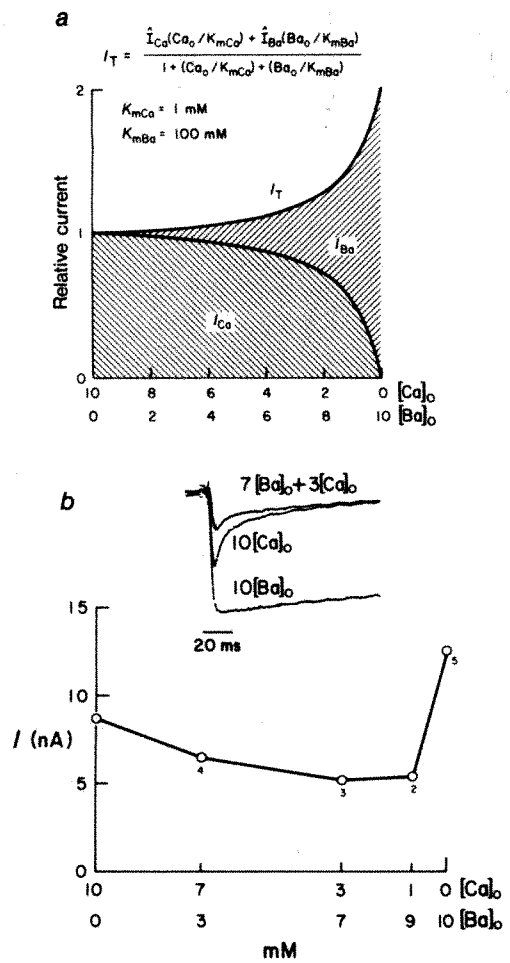

Fig. 2 The mole-fraction dependence of Ca channel current predicted for a channel with one ion-binding site (*a*) compared with that found experimentally (*b*). *a*, Computed values of total current (I_T) and its components I_{Ca} and I_{Ba}, calculated for a one-site channel using the equation shown. The dissociation constants of the site for Ca and Ba (K_{mCa} and K_{mBa} respectively) were chosen as shown in the inset. The maximum Ba current ($\hat{I}_{Ba}$) was made twice as large as the maximum Ca current ($\hat{I}_{Ca}$) because Ba currents are larger than Ca currents in these cells. No matter what values are chosen for K_{mCa}, K_{mBa}, $\hat{I}_{Ca}$ and $\hat{I}_{Ba}$, the one-site model always predicts that I_T is a monotonic function of the mole fraction. *b*, Peak amplitude of leak-subtracted inward current plotted against mole fraction. Voltage clamp pulse from −40 mV to +10 mV. To ensure that the anomalous mole-fraction dependence was not the result of rundown, the solutions were applied in the order indicated by the numbers next to each data point. Individual current records are shown in the inset. Cell 166A.

interactions between ions in the doubly occupied state[27,28].

The main uncertainty concerning the results in Fig. 2 is that changes in the peak current may not reflect changes in the current through open channels (*i*) but rather changes in the probability of channels being open (*p*). To measure single-channel current, we performed ensemble fluctuation analysis[29] on whole-cell recordings[30] from single frog ventricular cells[31]. Figure 3 shows a determination of *i* during the inactivation phase of Ca channel current. Estimates of *i*, the number of functional channels (N_F), and the peak probability of channel opening (p_{max}) are in reasonably good agreement with results of ensemble fluctuation analysis during the rising phase of Ca channel current[31]. As Fig. 3*c* shows, the main point here is that with $[Ca]_0 = 3$ mM and $[Ba]_0 = 7$ mM, *i* is significantly smaller than with $[Ca]_0 = 10$ mM or $[Ba]_0 = 10$ mM. Similar results were obtained in rat ventricular cells at a test potential of +20 mV (B. P. Bean and M. C. Nowycky, unpublished).

To explore the implications of the anomalous mole-fraction effect, we modelled the Ca channel as a single-file pore with

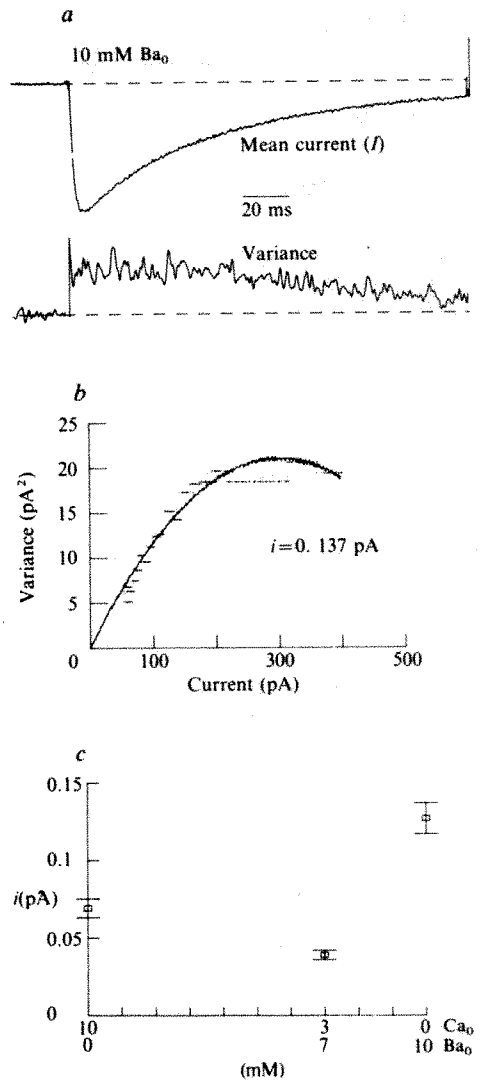

Fig. 3 The anomalous mole-fraction effect is a property of the open Ca channel. Single-channel currents were estimated by non-stationary fluctuation analysis[24] as illustrated in *a* and *b*. Whole-cell currents were recorded from single frog ventricular cells using the patch-clamp technique[25]. Fifty consecutive current records obtained with voltage steps from −60 mV to +10 mV were lined up in time and the mean and variance were calculated for each sampling point. The time course of the mean current (after subtraction of linear leak and capacity currents) and the variance are shown in *a*. The variance associated with the holding current was taken as the baseline (dashed line). *b*, Plot of the variance associated with the falling phase of the current as a function of the mean current. The data are fitted to the equation: variance = $iI - I^2/N_F$, where $I = N_F iP$. These equations describe the behaviour of N_F independent channels with a single-channel current *i* and a probability *P* of being open[29]. For the example shown, the best-fit parameters were $i = 0.137$ pA, $N_F = 4{,}340$ channels and $P_{max} = 0.66$. The external solution contained (in mM:): $BaCl_2$ 10, tetraethylammonium-Cl 135, $MgCl_2$ 1, HEPES 10 (*p*H 7.6). The patch pipette contained (in mM): CsCl 120, $MgCl_2$ 5, EGTA 10. Cell P11B. *c*, Mean (±s.e.m.) single-channel currents at a test potential of +10 mV determined by the method described above in 10 mM $[Ca]_0$ ($n = 7$ cells), 7 mM $[Ba]_0$ + 3 mM $[Ca]_0$ ($n = 6$) and 10 mM $[Ba]_0$ ($n = 7$).

two ion-binding sites (energy wells) and three energy barriers (for example, see refs 27, 28, 32). Figure 4*a* shows the various states of ion occupancy for the case of two permeant cations (for example, Ca and Ba). Rates of transition between connected states were calculated from Eyring rate theory, with energy profiles for Ca and Ba like those shown in Fig. 4*b*. For simplicity, the ion-binding sites (energy wells) were assumed to be equally spaced within the membrane; symmetry of energy profiles was

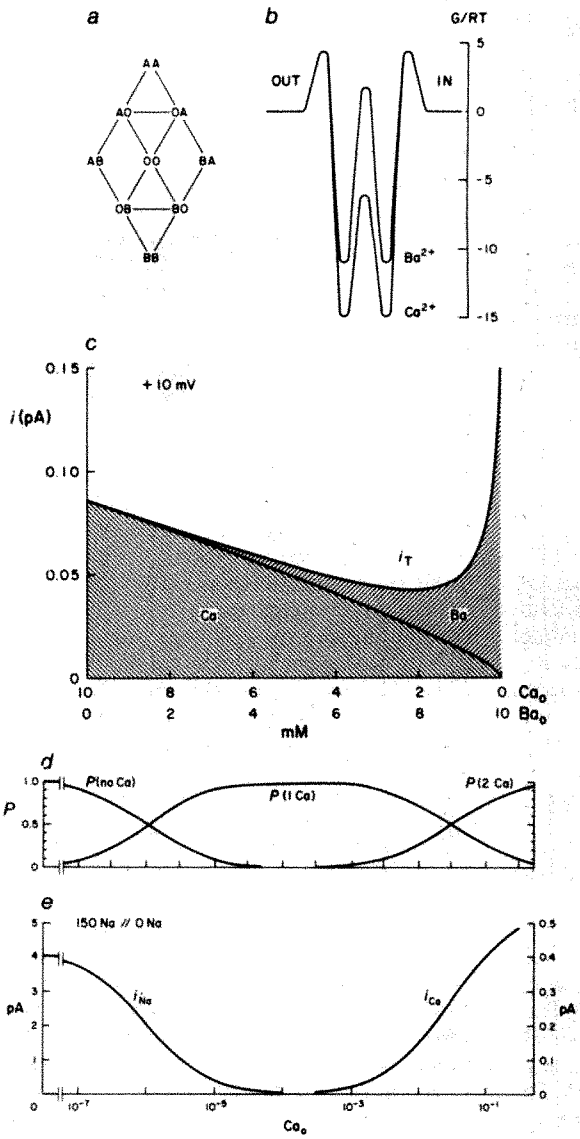

Fig. 4 Two-binding site model for the calcium channel. *a*, State diagram for the case of two ions. A and B, present on both sides of the membrane. An empty site is denoted by O. As the diagram indicates, single-filing is assumed. *b*, Free energy profiles for a single ion (Ca^{2+} or Ba^{2+}) in the absence of both an applied electric field and other ions within the channel. To reduce the number of adjustable parameters, barriers and wells are assumed to be spaced equally, 1/6th of the membrane thickness apart; chemical energy profiles are assumed to be symmetrical with respect to the centre of the membrane. As in earlier treatments of this type (see ref. 28 for earlier references), rates of transition were calculated by Eyring rate theory expressions of the form rate $= Q \exp(-\Delta G)$ (for entry rates this expression is multiplied by the ion activity in the medium from which the ion enters the channel). By convention, $Q = (kT\,h^{-1})$ as in treatments of ion permeation through Na and K channels[28,32,34]. The free energy change in surmounting a barrier ΔG is taken as the sum of three terms: a purely chemical ΔG^0 (as indicated in *b*), an electrical term $\pm(z_i V/6)$, and (when the far site is occupied) a repulsion term, $\pm z_i z_j \ln(F_{mm})$, where $F_{mm} = 3$ (z = valence and V = membrane potential). The choice of signs was determined by the direction of the transition relative to the applied electric field and to the position of the repelling ion. *c*, Calculated anomalous mole-fraction effect with $[Cs]_0 = 85$ mM and $[Cs]_i = 171$ mM (as in Fig. 2*b*), $[Ba]_i = 0$ and $[Ca]_i = 0$ at +10 mV. (Calculations with a computer model based on a program kindly provided by Dr T. Begenisich.) Activity coefficients for monovalents (divalents): 0.764 (0.341) outside and 0.725 (0.276) inside. Chemical component of energy profile for Cs^+ (in units of RT, where R is the gas constant and T is the absolute temperature): wells, −6, −6; barriers from outside to inside, 7.8, 10.3, 12.8. This profile also fits measured Ca channel reversal potentials with $[Ba]_0 = 10$ mM or $[Ca]_0 = 10$ mM and internal Cs[9,35]. Ca and Ba components of net current are shown; as Cs flux is less than 1.5% of net current magnitude, it is not shown. *d*, Occupancy of the channel by Ca as a function of $[Ca]_0$. Probabilities of the channel containing 0,1 or 2 Ca ions are shown at 0 mV in the presence of 150 mM external Na and no permeant internal ions. The chemical component of the energy profile for Na^+ (in units of RT: wells 1,1; barriers 6,8,10 from outside to inside) also fits measured reversal potentials of $[Na]_0$ versus $[Cs]_i$ and $[Ba]_0$ versus $[Na]_i$ (unpublished results). *e*, Elementary inward currents computed for the conditions assumed in *d*. At $[Ca]_0 < 10^{-4}$ M, inward current is carried by Na (i_{Na}); Ca only carries significant current at $[Ca]_0 > 10^{-4}$ M (i_{Ca}).

assumed in the absence of compelling reasons to the contrary. Ion–ion interactions were incorporated by a repulsion factor F which has the effect of making entry rates into a site F-fold slower and exit rates F-fold faster if the other site is occupied by another cation[28]. For monovalent–monovalent (mm) interactions, F_{mm} was set at 3 (well within the range expected for reasonable assumptions about the dielectric environment surrounding an aqueous pore[33]). For monovalent–divalent and divalent–divalent (dd) interactions, F was given by Coulomb's law without additional adjustable parameters: thus $F_{dd} = (F_{mm})^{2\cdot2} = 3^4 = 81$. Once specific values for the barrier heights and well depths are assigned to each ion, the model allows the computation of ion fluxes and ion occupancies in the presence of three permeant ions (for example, Ca, Ba and Cs).

A central feature of the model is that both binding sites have a high affinity for Ca ions. The postulated well depth for Ca of −15RT corresponds to an apparent dissociation constant of $\exp(-15) = 3 \times 10^{-7}$ M, three or four orders of magnitude lower than earlier estimates[10–16]. With the barrier heights and well depths shown in Fig. 4*b*, the model can account for the present experimental results: (1) calculated unitary currents exhibit an anomalous mole-fraction dependence (Fig. 4*c*); (2) Na movements through the channel are blocked by micromolar levels of Ca (Fig. 4*e*); while (3) Ca current increases as $[Ca]_0$ is elevated, with little saturation until $[Ca]_0$ reaches several millimolar (Fig. 4*e*). According to the model, these observations may be interpreted as follows.

The anomalous mole-fraction effect arises because the channel binds Ca^{2+} more strongly than Ba^{2+} and because Ca^{2+} and Ba^{2+} ions repel each other within the channel (see refs 27, 28). When the inner site is occupied by a Ca ion, a Ba ion entering across the outer barrier is very quickly repelled back out of its shallower well. Thus, equimolar replacement of external Ca by external Ba makes the current smaller at first because Ba^{2+} remains relatively impermeable until $[Ca]_0$ is low.

As Ca^{2+} binds so strongly, channel occupancy by a single Ca^{2+} is enough to block Na flux through the channel, and this occurs at micromolar levels of $[Ca]_0$. On the other hand, Ca flux through the Ca channel increases hand-in-hand with the probability of two Ca^{2+} ions in the channel (Fig. 4*d*, *e*). Because of mutual repulsion, this probability only becomes significant at millimolar $[Ca]_0$. Once double occupancy has occurred, repulsion promotes current flow. The presence of a Ca^{2+} at the outer site repels a Ca^{2+} at the inner site, increasing its chances of leaving that site and entering the cell. In this way, channel occupancy by Ca^{2+} tends to perpetuate itself, and Ca^{2+} strongly reinforces its own permeability. Only a second Ca^{2+} stays long enough to have a significant chance of displacing a predecessor Ca^{2+}. Like Ba^{2+}, Na^+ and other ions which bind less strongly than Ca^{2+} are quickly repelled out of the channel by Ca^{2+}.

This explanation helps resolve the controversy about the ionic basis of the 'slow inward current' (I_{si}) in cardiac muscle. On one hand, I_{si} has been called I_{Ca^{2+},Na^+} because Na^+ ions can support Mn^{2+}- and verapamil-sensitive action potentials or inward currents in the absence of external Ca[19]. On the other hand, in the presence of external Ca, prolonged removal of external Na reduces I_{si} very little[7,8]. Our results suggest that there is no contradiction between the channel's ability to support a large Na influx in the absence of Ca and its ability to reject Na in the presence of Ca. The high transport number for Ca in

physiological conditions justifies the simple label 'Ca channel' in the same way that the Na selectivity of tetrodotoxin (TTX)-sensitive channels justifies the name 'Na channel'.

This report is the first to argue that Ca channels are multi-ion, single-file pores, rather than one-ion pores that function by simple mutual exclusion. Our model is very different from the two-site model recently proposed by Kostyuk *et al.*[16]—they assumed that the pore can only contain one ion at a time and concluded that the channel selects for Ca over Ba at its outer binding site with $K_{mCa} = 10$ mM and $K_{mBa} = 100$ mM. To explain Ca^{2+} block of Na^+ influx, they had to postulate an additional external regulatory site with high affinity for Ca which controls the structure of the pore. Their model cannot account for the anomalous mole-fraction effect and it predicts that block of Ba currents by Ca^{2+} would require a $[Ca]_0$ at least 10 times higher than that described here.

As multi-ion pores, Ca channels resemble several other channels that are selective for Na, K or Cl; however, the proposed selectivity mechanism differs from previous descriptions of other biological channels. Unlike Na channels[32,34], Ca channels seem to bind the preferred ion more strongly than other physiological ions (see also refs 11, 16). Ca is selected as much by deep-energy wells as by a relatively low-energy barrier ('selectivity filter'). The nature of the binding site is of obvious importance. It is interesting to compare the Ca channel with Ca binding proteins such as troponin and calmodulin, or small organic Ca buffers such as EGTA. Like the proposed Ca binding sites in our model channel, the Ca-specific coordination sites on these molecules bind Ca^{2+} with high affinity (effective $K_d < 1$ μM), in preference to other cations (for example, Ba^{2+}, Sr^{2+}, Mg^{2+}, Na^+). Although detailed differences are to be expected, it seems possible that Ca channels and intracellular Ca receptors may share similar mechanisms of Ca selectivity.

After submission of this manuscript and publication of preliminary communications of this work[35,36], we received a manuscript with a similar theoretical treatment of Ca channels in skeletal muscle by W. Almers and E. W. McCleskey[37].

We thank K. S. Lee and E. W. Lee for help with preliminary experiments, T. Begenisich for sharing his computer model, B. Hille, B. P. Bean and M. C. Nowycky for valuable discussions, and A. P. Fox, O. S. Anderson and J. B. Lansman for comments on the manuscript. This work was supported by the USPHS.

Complete tyrosine-*O*-sulphation of gastrin in neonatal rat pancreas

S. J. Brand*, B. N. Andersen & J. F. Rehfeld

University Department of Clinical Chemistry, Rigshospitalet, DK-2100 Copenhagen, Denmark

Modification of tyrosine residues of proteins has attracted great interest. Although phosphorylation has received most attention[1–3], tyrosine-*O*-sulphation is also common[4] and has been closely investigated in the hormones gastrin and cholecystokinin (CCK). CCK regulates pancreatic enzyme secretion. It is always sulphated[5–9] and sulphation increases its pancreatic secretagogue activity 100-fold[10–13]. By contrast, only half of gastrin molecules are tyrosine-*O*-sulphated[5–9] and sulphation does not influence the ability of gastrin to regulate gastric acid secretion[6]. We now report that in neonatal rat pancreas, which is the major source of gastrin in the newborn rat[14], gastrin is completely sulphated. Moreover, the disappearance of gastrin from the pancreas during the first weeks after birth parallels the appearance of CCK in the intestine. Since sulphation is essential for pancreatic secretagogue activity of gastrin as well as of CCK[10–13], pancreatic gastrin in the neonate may be the equivalent of intestinal CCK in the adult.

The pancreas, antrum and small intestine of 0-, 4-, 7-, 14- and 21-day-old Wistar rats and of 17-day fetuses were dissected out and frozen immediately on dry ice. Tissues were extracted by boiling in water and the pellet was re-extracted in cold 0.5 M acetic acid. The concentrations of gastrin and CCK in the extracts were measured by sequence-specific radioimmunoassays (RIAs), including one which distinguishes between non-sulphated and sulphated peptides[9,15–17]. The extracts were further analysed by Sephadex G-50 superfine chromatography and ion-exchange HPLC (see Fig. 3 legend). Both gel and ion-exchange chromatography were monitored using gastrin RIAs, one (using antiserum no. 2604) measuring sulphated and non-sulphated gastrins[15] and another (using antiserum no. 2605) measuring only non-sulphated gastrins[9,16].

Figure 2 shows the fetal and postnatal changes in pancreatic gastrin and intestinal CCK concentrations. At birth, pancreatic gastrin concentration was high whereas gastrin and CCK concentrations in the small intestine were low, relative to adult concentrations. After the fourth postnatal day, pancreatic gastrin rapidly disappeared, concomitant with the appearance of CCK in the intestine.

Gel chromatography of the pancreatic extracts followed by RIA using the antiserum that binds both sulphated and non-sulphated gastrins revealed only one peak of immunoreactivity, in a position corresponding to 'little' gastrin (or gastrin-17), and which was not recognized by the antiserum that binds only non-sulphated gastrins. The pancreatic and antral little gastrin was further characterized by high-pressure ion-exchange chromatography of the gastrin-containing fractions from the gel chromatography. By contrast with antral gastrin which was partially sulphated, gastrin from the neonatal pancreas was completely sulphated. Gastrin immunoreactivity in the pancreas co-eluted with both sulphated antral gastrin immunoreactivity (Fig. 3*a*, *b*) and biosynthetically ^{35}S-sulphate-labelled gastrin (Fig. 3*a*, *c*). Moreover, pancreatic gastrin was desulphated by treatment with limpet arylsulphatase (Fig. 3*d*).

Antral little gastrin was resolved by ion-exchange chromatography into four peaks (Fig. 3*b*), probably representing sulphated and non-sulphated forms of gastrin-15 and -17, since rat gastrin-17 contains arginine (Fig. 1) one amino acid after the dibasic cleavage site of gastrin-17 (ref. 18). These identifications were confirmed by the observation that on ion-exchange chromatography of trypsin-treated antral gastrin, there was a single peak for each of sulphated and non-sulphated gastrin

Fig. 1 The primary structure of heptadecapeptide gastrin from rat[18], pig[27] and of the C-terminal heptadecapeptide fragment of pig CCK[5]. The heptadecapeptide amide is the principal hormonal form of gastrin. The homologous C-terminal sequences containing the biologically active sites of both gastrin and CCK are underlined. The sulpho-tyrosine groups of the gastrins are given in brackets, since only half of the gastrin-17 molecules in rat and pig antral mucosa are sulphated, in contrast to the completely sulphated porcine CCK.

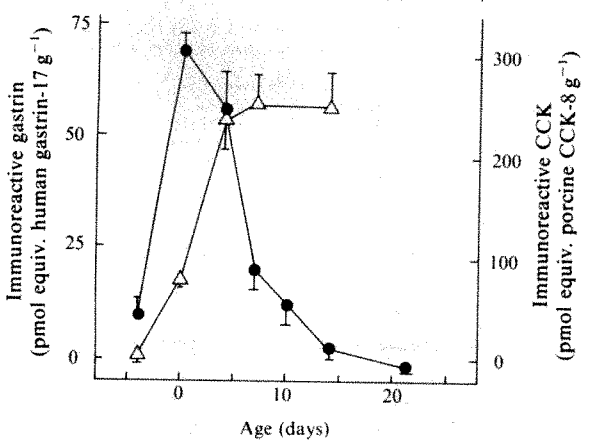

Fig. 2 The neonatal changes of gastrin in the pancreas (●) and CCK in the small intestine (△) of the rat. The number of rats for each point is 20 pooled in five groups of 4. Gastrin was measured in aqueous extracts with a specific RIA using a rabbit antiserum (2604; ref. 15), which detects sulphated and non-sulphated gastrins with equimolar potency, but CCK negligibly ($P < 0.0006$). CCK was measured in both aqueous and acetic acid extracts of intestine in a specific CCK RIA[17], using a rabbit antiserum (G-160; ref. 28) with which sulphated gastrins react at less than 0.005% and non-sulphated gastrins not at all.

(data not shown). Most of the pancreatic gastrin co-eluted with the trypsin-labile peak of little gastrin extracted from rat antrum and is thus presumably gastrin-17, although a small peak of sulphated gastrin-15 was also seen (Fig. 3*a*). The proximal small intestine contains moderate amounts of gastrin in the fetal, neonatal and adult rat (ref. 14 and this study). In both adult and neonate, however, this intestinal gastrin was similar to antral gastrin in being only partially sulphated.

Although the physiological significance of the transient expression of gastrin in the neonatal pancreas is not yet clear, the fact that it is completely tyrosine-*O*-sulphated suggests a CCK-like action on surrounding exocrine cells by a paracrine mode of release. Tyrosine-*O*-sulphation of CCK increases pancreatic acinar receptor binding and secretagogue potency by 100-fold[11,12]. Although sulphated gastrin is a weaker stimulus than sulphated CCK, this would be compensated for by the higher concentrations achieved through intrapancreatic release. Birth heralds a transition from placental to alimentary nutrition, so the dramatic changes in pancreatic gastrin and intestinal CCK concentrations in the neonate (Fig. 2) would seem to be related to the start of feeding. Pancreatic gastrin levels rise just prior to birth, before food is present in the intestinal lumen. After birth, CCK appears in the intestine and pancreatic gastrin rapidly disappears as intestinal stimuli become more important in controlling pancreatic function. Pancreatic gastrin may therefore be important in stimulating rapid pancreatic development at birth to ensure adequate digestion when feeding commences.

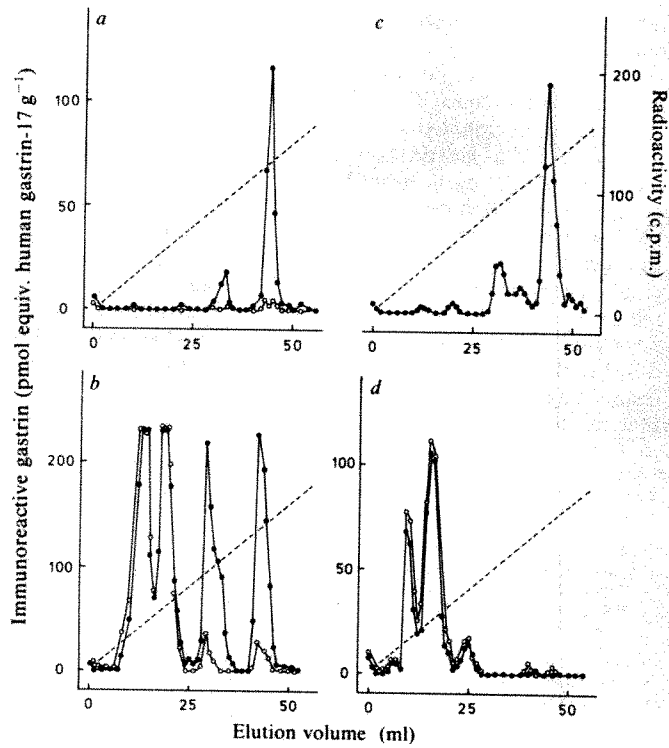

Fig. 3 *a*, Sulphation of gastrin in neonatal pancreas. Extracts were applied to a 5×50 mm Mono-Q HR5/5 anion-exchange column (Pharmacia) equilibrated with 20 mM sodium phosphate, *p*H 6.5. The column was washed with 10 ml 0.01% v/v acetic acid and eluted with a gradient from 0.01% to 12.5% acetic acid (----) over 50 min at room temperature with a flow of 1 ml min^{-1} (ref. 29). One-minute fractions were collected and assayed after removing the acetic acid by freeze-drying with two gastrin RIAs using antisera 2604 (●) and 2605 (○). *b*, Sulphation of gastrin in antral extracts fractionated on Mono-Q anion-exchange column as described above. Gastrin was measured by RIAs using antisera 2604 (●) and 2605 (○) as described above. *c*, ^{35}S activity (c.p.m.; ●) from slices of rat antrum incubated with ^{35}S-sulphate in sulphate-free Hank's media for 4 h. Antral extracts were then applied to a Seppak cartridge (Waters Associates), washed extensively, eluted with methanol, dried and applied to a Sephadex G50 column. The gastrin-17-like immunoreactivity was pooled and applied to a Mono-Q column and eluted as above and ^{35}S-sulphate radioactivity counted by liquid scintillation. Incorporation of ^{35}S-sulphate activity was directly confirmed by two-dimensional thin-layer electrophoresis of alkaline hydrolysates of the peptide[4]. All the ^{35}S-sulphate radioactivity co-migrated with tyrosine-*O*-sulphate standard. *d*, Pancreatic gastrin purified by gel chromatography was treated with limpet arylsulphatase (Sigma S8629). Dried peptide was dissolved in 800 μl of 0.2 M sodium acetate, *p*H 5, and 250 μg arylsulphatase, dissolved in 100 μl 0.2% sodium chloride, were added and the mixture incubated at 37 °C for 2 h. The incubation mixture was diluted with water and then applied to a Mono-Q anion-exchange column, eluted as above and gastrin measured by RIA using antisera 2604 (●) and 2605 (○).

In addition to stimulating pancreatic growth and secretion, gastrointestinal and pancreatic peptides also stimulate enzyme synthesis. Although this action is best understood for insulin, which selectively stimulates amylase gene transcription[19], CCK-like peptides may also stimulate trypsin and chymotrypsin synthesis[20]. These actions may be especially important in the neonate as just before parturition pancreatic enzyme concentrations rise markedly[21]. Pancreatic insulin[21] and gastrin concentrations (this study) also show parallel rises just before parturition, suggesting that these hormones induce enzyme synthesis in the surrounding exocrine cells. Whether the actual synthesis of pancreatic gastrin including the tyrosine-*O*-sulphation, is controlled by mechanisms inherent in the gastrin-producing cell

DNA or by signals from the environment, remains to be determined.

The complete sulphation of gastrin is not restricted to the neonatal rat pancreas. The feline pancreas contains gastrin that is completely sulphated and, although the normal human pancreas is devoid of gastrin, the small intestine of the human fetus contains 30-fold more gastrin than CCK and all the gastrin molecules are sulphated. After birth, the concentration of intestinal gastrin declines and gastrin assumes the adult partly-sulphated pattern (B.N.A., in preparation). Some human pancreatic gastrinomas contain only sulphated gastrin[22]. In view of the localization of essentially all malignant gastrinomas to the pancreas[23] and the homology between sulphated gastrin and the transforming middle-T antigen of polyoma virus[24], the present results may also be of relevance to oncogenesis. Note, however, that the homology is less pronounced in the sequence corresponding to the active site of gastrin, the C-terminal tetrapeptide amide.

It has previously been suggested that important changes can occur in peptide processing during neonatal development[25,26]. Our results support the contention that an organ at different stages of development can be regulated by different peptides through modulation of a post-translational modification critical for receptor binding.

We thank Mrs Birgitte Lindsey and Mrs Brith Simonsen for technical assistance and H. F. Hansen for discussions and help with the ion-exchange HPLC. S.J.B. thanks Professor W. J. Simmonds for help and encouragement. The study was supported by grants from the Australian and Danish MRC and from the NOVO Foundation. S.J.B. was supported by a Sobodtka Postgraduate Scholarship from the University of Western Australia.

Expression and amplification of the N-*myc* gene in primary retinoblastoma

Wen-Hwa Lee*, A. Linn Murphree & William F. Benedict

Clayton Molecular Biology Program, Divisions of Hematology-Oncology and Ophthalmology, Childrens Hospital of Los Angeles, 4560 Sunset Blvd, Los Angeles, California 90027, USA

Retinoblastoma, the most common intraocular tumour of childhood, probably arises from embryonal cells and occurs in hereditary and non-hereditary forms[1]. Recent evidence suggests that this retinoblastoma (*Rb*) susceptibility gene located at chromosome 13q14 is actually recessive[2–4]. Knudson has proposed that the tumour is caused by two mutational events[5]. This idea was extended by Comings[6], who suggested that dominantly inherited tumours may result from loss or inactivation of both alleles of regulatory or suppressor genes that, when active, prevent the expression of a structural transforming gene(s) (possibly an oncogene) normally active only during embryogenesis. Despite circumstantial evidence[3,4,7,8] for this hypothesis, no activated oncogene[9–14] has been identified. We now report that (1) the N-*myc* gene is amplified 10–200-fold in two primary retinoblastomas and a retinoblastoma cell line Y79 and (2) expression of N-*myc* gene is highly elevated in most of the retinoblastomas examined. This finding suggests that N-*myc* gene may have a primary role in the tumorigenesis of retinoblastoma.

Genomic DNA was prepared from 10 primary retinoblastomas, 3 of which are described here for the first time. The other seven tumours have been karyotyped and reported previously[8] (Table 1). Various oncogenes were used as probes in the Southern genomic blotting analysis[15,16]. We found that two tumours (LA-RB70 and LA-RB63-1A), both of which contain extrachromosomal double minutes (DMs) (Table 1), and the Y79 cell line which contains a homogeneously staining region (HSR), all possessed a 2-kilobase (kb) *Eco*RI fragment in addition to the 13.5-kb c-*myc* fragment which demonstrates homology to the v-*myc* probe (data not shown). Both DMs and HSRs have been implicated in gene amplification of the N-*myc* in neuroblastoma[17,18]. Our results suggest that the retinoblastomas LA-RB70, LA-RB63-1A and Y79 show a similar amplification of the N-*myc* gene. Because the homology between c-*myc* and N-*myc* is limited[17,18], the N-*myc* sequences must be amplified to be detected by the v-*myc* probe in the Southern blotting. However, we found no gross abnormalities of the c-*myc* gene in these samples.

To confirm that the 2-kb *Eco*RI fragment is the N-*myc* gene, the pNb-1 plasmid (provided by Dr M. Bishop), which contains part of the known N-*myc* gene, was used as probe. We found that LA-RB70, LA-RB63-1A and the Y79 cell lines do indeed contain one amplified 2-kb *Eco*RI fragment which hybridizes with the pNb-1 probe (Fig. 1*a*). To exclude the possibility of technical artefacts, the pT24-C (c-H-*ras*) probe was also used in the same blot. Two *Eco*RI fragments of about 15 and 9 kb were hybridized with approximately equal intensity in every lane of DNA (data not shown). The extent of the amplification of the N-*myc* gene was determined by applying different amounts of DNA for Southern blotting. As Fig. 1*b* shows, compared with the level of N-*myc* gene in normal fibroblasts or other tumours, LA-RB70 and Y79 contain a 100–200-fold amplification of the N-*myc* gene and LA-RB63-1A contains a 10–20-fold amplification. Amplification of the N-*myc* gene in Y79 cells has also been described by Kohl *et al.*[18]. As the Y79 cell line has been in culture for many years, the amplification of the N-*myc* gene may be a result of clonal selection in culture rather than amplification in the original cells. However, the fact that the gene is amplified in the LA-RB70 and LA-RB63-1A tumours indicates that it can be amplified in the primary retinoblastoma or early passaged tumour cells.

Meanwhile, we prepared and analysed DNA from the fibroblasts of three patients with retinoblastomas—LA-RB63-1A (a patient whose tumour showed amplification of the N-*myc* gene), LA-RB69 and LA-RB73—as well as from fibroblasts of one normal human embryo. No amplification of the N-*myc* gene was found in these cells (Fig. 1*c*). These results indicate that as

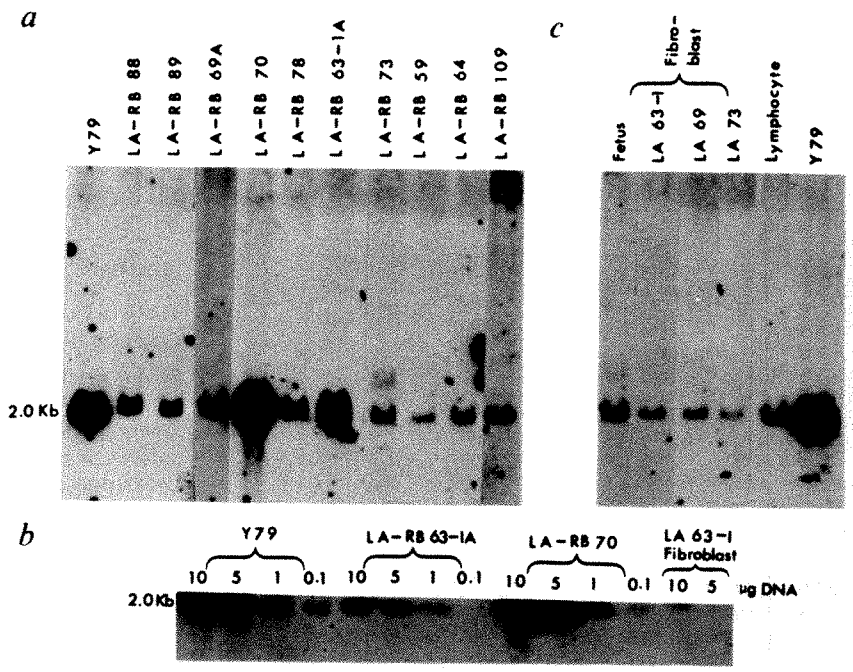

Fig. 1 Southern blot analysis of DNA from retinoblastomas and normal fibroblasts, probed with ^{32}P-labelled pNb-1 DNA. *a*, Amplification of N-*myc* gene in retinoblastoma DNA. A 2-kb *Eco*RI resistant fragment representing the N-*myc* gene was hybridized with pNb-1 probe in all DNA samples. Three cases, Y79, LA-RB70 and LA-RB63-1 contained an amplified N-*myc* gene. In addition to the 2-kb fragment, a 3-kb fragment of LA-RB73 was also hybridized. The significance of this hybridization is not known. *b*, Determination of the N-*myc* gene amplification fold. Different amounts of DNA were digested with *Eco*RI, and following Southern analysis, probed with pNb-1. Fibroblast DNA from the LA-RB63 patient was used as a standard for comparison. Part of the blot containing the 2-kb fragment region is shown in the figure. *c*, Normal fibroblast DNA from retinoblastoma patients had no amplification of the N-*myc* gene. Fibroblast DNA from three retinoblastoma patients, including one whose retinoblastoma contained N-*myc* amplification, one normal fetus and one adult lymphocyte DNA were subjected to Southern analysis, then probed with pNb-1 as described below. In the same blot, an equal amount of Y79 DNA was used for positive control.

Methods: Genomic DNA was prepared by the standard method[25] and ~10 µg of each DNA sample were digested by *Eco*RI to completion, electrophoresed through 0.8% agarose and blotted onto nitrocellulose. Hybridization with nick-translated ^{32}P-labelled pNb-1 DNA (specific activity 2.5×10^8 c.p.m. µg^{-1}) was in 40% formamide, 5×SSC at 42 °C for 36–48 h. Washing was done in 0.2×SSC, 0.5% SDS at 55 °C.

N-*myc* gene amplification occurred solely in tumour tissue, expression of this sequence could have an aetiological role in retinoblastoma formation.

It remained possible that abnormalities of other oncogenes existed in the eight tumours in which N-*myc* was not amplified at the DNA level. However, when *ras*, *ets*, *myb*, *erb* and *fps* were used as probes[10] to determine if there had been any rearrangements or other changes of these oncogenes, no gross abnormalities were found in any tumour (data not shown), although we cannot exclude the possibility that a point mutation has occurred in those genes which could be important for tumour formation.

Gene amplification is only one of several mechanisms for increasing gene expression[19]. To determine whether there was increased expression of N-*myc* in retinoblastoma at the mRNA level and whether this expression is specifically associated with gene amplification, we prepared RNA from 10 individual tumours, the Y79 cell line, four different fibroblast samples, one human fetal retina and one bovine retina. This RNA was then used to perform RNA dot analysis[20] using the pNb-1 as probe. We found that the Y79 cell line and four retinoblastomas (LA-RB63-1, LA-RB70, LA-RB78 and LA-RB109) expressed about 100-fold higher levels of N-*myc* mRNA than did retinal cells. The other tumours also had elevated levels of N-*myc* mRNA expression. However, N-*myc* expression was essentially undetectable in the fibroblasts (Fig. 2).

The LA-RB63-1A and LA-RB70 tumours as well as the Y79 cell line contained an amplified N-*myc* gene and consequently the presence of a high level of N-*myc* mRNA was anticipated. However, the other tumours did not contain detectable amplification of the N-*myc* gene, yet expressed a high level of N-*myc* mRNA, varying within four to fivefold. We do not know the significance of this difference. This increased expression might be due to the loss or inactivation of both alleles of a regulatory gene or a mutation at the regulatory site of the N-*myc* gene. If the first possibility is true, the *Rb* gene in 13q14 might actually be a regulator of N-*myc* expression.

We also analysed mRNA from neuroblastoma cell lines LA-N-1, LA-N-5 and SKN-SH as controls. The LA-N-1 and LA-N-5 cells showed a high level of N-*myc* expression[18] whereas two SKN-SH cell line variants contained neither amplified levels of the N-*myc* gene nor increased mRNA expression (Fig. 2). We emphasize that N-*myc* amplification appears to occur primarily

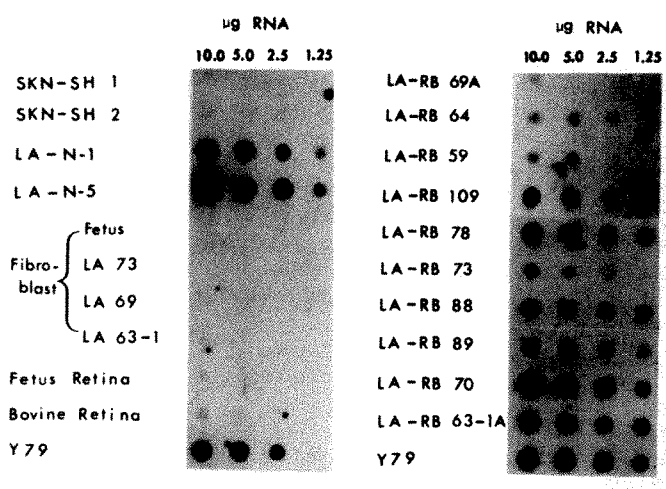

Fig. 2 Dot analysis of RNA from retinoblastoma, fibroblast, neuroblastoma and retina cells. Total cytoplasmic RNA was prepared by a method using Nonidet-P40 to lyse the cell membrane, followed by phenol–chloroform extraction[25]. RNA was precipitated by ethanol and quantitated with A_{260} and directly dotted onto a nitrocellulose membrane in 20× SSC. Hybridization was in 50% formamide and 5× SSC at 42°C with pNb-1 as probe. Washing was done in 0.2× SSC and 0.5% SDS at 60°C. Due to the limited amount of samples, some of the lanes contain RNA only in the first one or two dots.

in the advanced metastatic stages of neuroblastoma[21], which implies that the N-*myc* gene may be involved in the progression of malignancy in this disease. In contrast, except for LA-RB78 which was obtained from a rib metastasis, all other retinoblastomas with increased N-*myc* either at the gene or mRNA level were obtained as relatively small non-metastatic intraocular tumours. As these tumours included both hereditary (bilateral) and non-hereditary (most unilateral) cases (Table 1), the possibility exists that increased N-myc expression has a more fundamental role in retinoblastoma formation.

Although the N-*myc* gene has a limited sequence homology to the c-*myc* gene, the oncogenic potential of this gene is unknown. A suitable *in vitro* assay system to test the transforming ability of the N-*myc* gene should provide information on this issue. Nevertheless, the positive correlation between N-*myc*

Table 1 Summary of retinoblastomas used in the present study

Tumour designation	Tumour material used	Bilateral (B) or unilateral (U) case	Presence of DM or HSR	N-*myc* gene amplification	N-*myc* mRNA expression
LA-RB59	SQP 1*	U	–	—	+
LA-RB63-1A	SQP 1	B	+	10–20	+++
LA-RB64	SQP 1	U	–	—	+
LA-RB69A	EP 9†	B	–	—	+
LA-RB70	Primary	U	+	100–200	+++
LA-RB73	Primary	B	–	—	+
LA-RB78	SQP 2	U	–	—	+++
LA-RB88	Primary	B	–	—	++
LA-RB89	Primary	U	–	—	++
LA-RB109	Primary	U	–	—	+++
Y79	Cell line	B	+	100–200	+++

Tumours LA-RB59 to LA-RB78 have been described in ref. 8. Tumour LA-RB78 was obtained from rib metastasis rather than intraocular tumour. DM, extrachromosomal double minutes; HSR, homogeneously staining region; +, high level of expression; –, not found.

*Subcutaneous passage in nude mice.

†Eye passage in nude mice.

amplification in neuroblastoma and N-*myc* expression in the retinoblastoma strongly suggests that the N-*myc* gene may implies that the N-*myc* gene may be involved in the progression of malignancy in this disease. In contrast, except for LA-RB78 which was obtained from a rib metastasis, all other retinoblastomas with increased N-*myc* either at the gene or mRNA level were obtained as relatively small non-metastatic intraocular tumours. As these tumours included both hereditary (bilateral) and non-hereditary (most unilateral) cases (Table 1), the possibility exists that increased N-*myc* expression has a more fundamental role in retinoblastoma formation.

Several human tumours, including retinoblastoma, Wilms' tumour and neuroblastoma, are associated with specific chromosomal deletions[23]. The recessive nature of a relevant gene for tumour formation in the deleted band has been demonstrated for the *Rb* gene[1,3,4] and is likely for Wilms' tumour[24]. We speculate that recessive genes like the *Rb* gene in these tumours may have a regulatory role to modulate a set of proto-oncogenes. This hypothesis can be tested when the molecular nature of the *Rb* gene is elucidated.

We thank Drs M. Bishop, P. Duesberg, S. Aaronson and E. Chang for giving us the oncogene probes, Dr R. Seeger for providing the LA-N-1 and LA-N-5 neuroblastoma cell lines, Dr S. Hinrichs for fetal retina tissue, Dr D. Dolberg for critical review of this manuscript, Drs M. Bissell, G. Parry and J. Bartholomew for allowing W.-H.L. to work in their laboratory, and C. Mark for his preparation of retinoblastoma specimens. This work was done in conjunction with the Clayton Foundation for Research.

Identification of a form of the avian erythroblastosis virus *erb-B* gene product at the cell surface

Avian erythroblastosis virus (AEV) induces both erythroblastosis and fibrosarcoma in chickens[1]. The viral oncogene responsible for these diseases, *erb*, is divided into two regions, *erb-A* and *erb-B*, although recent evidence suggests that it is primarily the *erb-B* gene product that is responsible for the transforming activity[2–5]. The *erb-B* gene product has been reported previously to be a membrane glycoprotein of 68,000 molecular weight (MW), gp68^{erb-B} (refs 6, 7). However, we show here that gp68^{erb-B} is an intracellular precursor which is modified further to a 74,000 MW protein, gp74^{erb-B}. By the criteria of resistance to digestion with endoglycosidase H, subcellular fractionation and inhibition of biosynthesis by the ionophore monensin, gp74^{erb-B} appears to be located at the cell surface. Recently, a comparison of the *erb-B* sequence[8] with that of the epidermal growth factor (EGF) receptor has shown that these two genes are highly homologous[9], and that *erb-B* appears to represent a truncated form of this growth factor. In light of these data the identification of gp74^{erb-B} at the plasma membrane suggests that this may be the functionally important form of the *erb-B* gene product.

Identification of homology between the *erb-B* gene product and the tyrosine kinase domains of other viral oncogenes[8] prompted us to propose that the *erb-B* gene product may function as a growth factor receptor[6,10,11]. Our hypothesis has recently been confirmed with the demonstration that *erb-B* shows near identity with the carboxy-terminal third of the human EGF receptor[9], and suggests that *erb-B* functions as a truncated growth factor receptor. However, this highlighted the major problem with our original hypothesis, namely the inability to detect a form of the *erb-B* glycoprotein that exhibited the hallmarks of a classic plasma membrane protein, for if *erb-B* functions as a growth factor receptor it should lie in the plasma membrane. It was therefore possible that a more mature form of the *erb-B* protein existed which we had failed to identify. We considered this highly possible, as our antisera raised in tumour-bearing rats recognized both the *erb-A* and *erb-B* proteins, and a form of the *erb-B* protein could be obscured by the *erb-A*-encoded protein p75^{erb-A} (ref. 12).

While screening antiserum from tumour-bearing rats which had been injected with lower numbers of AEV-transformed rat-1 cells than used previously[6], we identified 10 out of 60 animals tested which produced *erb-B*-specific antibodies. These antisera were used to analyse the *erb-B* proteins in greater detail. Immunoprecipitation analysis (Fig. 1*a*, track 2) revealed that these antisera precipitated only the *erb-B* proteins gp66 and gp68 from the AEV-transformed erythroblasts, whereas our original tumour-bearing antisera precipitated both the p75^{erb-A} and the *erb-B* proteins (Fig. 1*a*, track 3). Normal rat serum did not precipitate any of these proteins (Fig. 1*a*, track 4).

Our initial aim in preparing *erb-B*-specific antisera was to identify forms of the *erb-B* glycoprotein that had gone undetected in our previous studies. An examination of the ^{35}S-methionine-labelled proteins precipitated by the *erb-B*-specific serum failed to reveal any additional proteins (Fig. 1*a*, track 2). However, when the AEV-transformed erythroblasts were labelled for 16 h with ^{3}H-glucosamine, an additional protein of 74,000 MW, gp74, was obtained (Fig. 1*a*, track 1). This protein

* Present address: Imperial Cancer Research Fund Laboratories, St Bartholomew's Hospital, Dominion House, Bartholomew Close, London EC1A 7BE, UK.

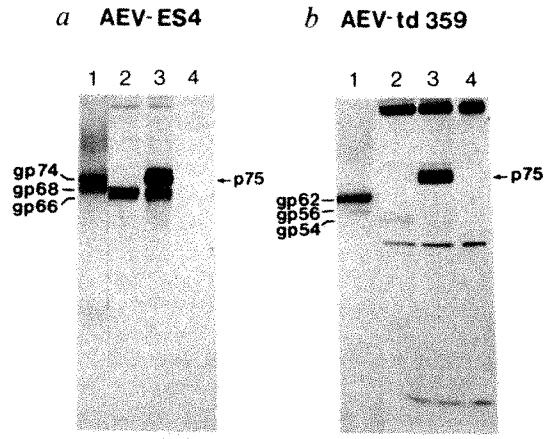

Fig. 1 Identification of *erb-B*-specific antiserum. Erythroblasts transformed by AEV-ES4 (panel *a*) or an isolate of AEV-*td*359 recovered from an infected chicken (panel *b*) were labelled with 100 μCi of ^{35}S-methionine for 30 min (tracks 2–4) or 500 μCi ^{3}H-glucosamine for 16 h (track 1). Immune precipitates were formed using rat anti-*erb-B* serum (tracks 1, 2), rat anti-*erb-A* plus *erb-B* (track 3) or normal rat serum (track 4). The precipitates were analysed by SDS-polyacrylamide gel electrophoresis and the labelled proteins were visualized by fluorography. The films were exposed for 2 days for tracks 2–4, and 3 weeks for track 1. Anti-*erb* serum was prepared by injection of 10^5–10^6 AT1a cells intraperitoneally into 10–14-day-old (Fischer × Wistar)F_1 rats as described previously[6]. The sera were collected 10–12 weeks later and tested for anti-*erb* activity by immunoprecipitation.

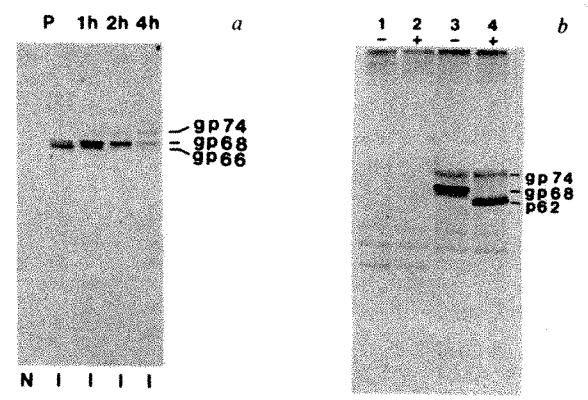

Fig. 2 Pulse-chase and endo-H digestion analysis of the *erb-B* glycoprotein. *a*, Erythroblasts transformed by AEV-ES4 were labelled for 30 min with 100 μCi ^{35}S-methionine. The cells were then pelleted and resuspended in complete growth medium. An aliquot of cells was removed for time point zero (P) and subsequent aliquots were removed after 1, 2 or 4 h. Detergent lysates were prepared and immune precipitates formed with either normal rat serum (N) or rat anti-*erb-B* serum (I). *b*, AEV-ES4-transformed erythroblasts were labelled for 30 min with ^{35}S-methionine, pelleted and resuspended in complete growth medium. The cells were then incubated for a further 3 h, collected and detergent lysates prepared. Immune precipitates were then formed with either normal rat serum (tracks 1, 2) or rat anti-*erb-B* serum (tracks 3, 4). The immune precipitates were then halved and one-half was treated with endo-H (+) as described previously[15]. The other half of the sample was treated in exactly the same way but without the addition of endo-H(−). All samples were analysed on a 10% SDS-polyacrylamide gel.

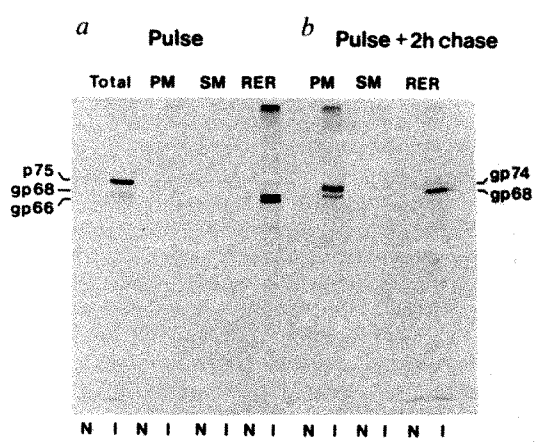

Fig. 3 Localization of gp74^{erb-B} to the plasma membrane. AEV-ES4-transformed erythroblasts were labelled for 30 min with 500 μCi of ^{35}S-methionine, and pelleted at 1,500*g* for 5 min. They were then resuspended in growth medium, and an aliquot (~10%) of the cells was taken to check the total incorporation (Total). From the remainder, half were removed for time point zero (*a*), the rest were incubated for a further 2 h (*b*). Both cell populations were then fractionated into plasma membrane (PM), smooth membrane (SM) and rough endoplasmic reticulum (RER)-enriched membrane populations, the fractions were characterized by buoyant density, RNA content and the presence of marker enzymes as described previously[6,16,17]. The membranes were dissolved in 0.5% NP40, 0.5% DOC, 50 mM Tris-HCl *p*H 8.1, 100 mM NaCl, and immune precipitates formed with either normal rat serum (N) or anti-*erb-A* + *B* serum (I). The precipitates were analysed on a 10% SDS-polyacrylamide gel and the proteins visualized by fluorography after 10 days' exposure.

was precipitated by the *erb-B*-specific serum from extracts of AEV-transformed erythroblasts (Fig. 1*a*, track 1) or fibroblasts (data not shown), suggesting that it was either an *erb-B*-encoded protein or a cellular protein. To distinguish between these possibilities, we used AEV-rtd359, a back mutant of AEV-*td*359 which has recovered the ability to transform erythroblasts but which has a deletion in *erb-B* and synthesizes *erb-B* proteins that are 12,000 daltons smaller than the wild-type protein (T. Graf, M.J.H., H.B. and B. Vennström, unpublished observations). Therefore, if gp74 was in fact encoded by *erb-B*, one would expect a glucosamine-labelled protein of a smaller size. The ^{35}S-methionine-labelled *erb-B* protein of AEV-rtd359 had MWs of 54,000 and 56,000 (Fig. 1*b*, track 2), the ^{3}H-glucosamine-labelled proteins were of MWs 56,000 and 62,000 and no gp74 was identified in these cells (Fig. 1*b*, track 1). These data show that the gp74 glycoprotein is not a cellular protein, as it would have been detected in all the transformed erythroblasts. In addition, because there is a ^{3}H-glucosamine-labelled protein 6,000–10,000 daltons larger than the largest ^{35}S-methionine-labelled *erb-B* protein in both AEV strains, the data strongly suggest that these larger forms are products of the *erb-B* gene.

The presence of ^{35}S-methionine-labelled gp74 was investigated by pulse-chase analysis and precipitation of the lysates with *erb-B*-specific antiserum. Following a 30-min pulse-label, both gp66 and gp68 were found in the cells (Fig. 2*a*), and during the chase period gp66 was processed into gp68, as shown previously[6]. However, after a 1-h chase period, gp74 was also found in the cells, the amount increasing after 2 h and reaching a steady-state level by 4 h (Fig. 2*a*). Interestingly, the amount of label found in gp74 accounts for only ~25% of that initially detected in gp66 and gp68 (Fig. 2*a*). This means either that only 25% of the newly synthesized *erb-B* protein was processed into the gp74 form and the rest was rapidly degraded intracellularly or that the gp74 protein is being sequestered to a pool that is no longer detectable.

Digestion with the enzyme endoglycosidase H (endo-H)[13] had shown previously that both gp66 and gp68 were sensitive to digestion by this enzyme[6]. To see if gp74 was also sensitive to digestion, cells were labelled for 30 min with ^{35}S-methionine and chased for 3 h to allow the formation of gp74. Figure 2*b* shows that the gp68 form is still sensitive to endo-H, whereas the gp74 form is completely resistant to this enzyme, indicating that the carbohydrate chains on gp74^{erb-B} have been processed into the complex form.

Analysis of gp66^{erb-B} and gp68^{erb-B} by subcellular fractionation had localized these proteins to the microsomal fraction of the cell[6]. However, these previous studies had not distinguished

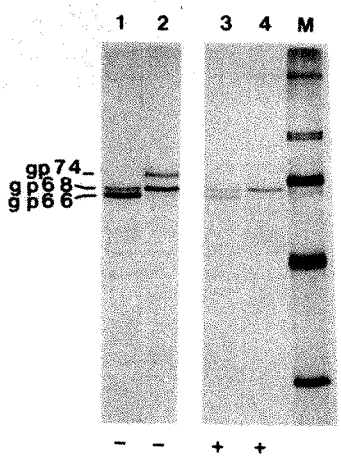

Fig. 4 Monensin inhibits the formation of gp74$^{erb\text{-}B}$. AEV-transformed erythroblasts were preincubated for 2 h in the absence (−) or presence (+) of 10 μM monensin (a kind gift of Dr M. Owen). Cells were then labelled for 30 min with ^{35}S-methionine, one population in the absence and the other in the presence of 10 μM monensin. The cells were pelleted and half taken from each population for the pulse time point (tracks 1, 3), the rest being resuspended in growth medium and incubated for a further 2 h, again in the absence (−) or presence (+) of 10 μM monensin (tracks 2, 4). Detergent extracts were prepared and immune precipitates formed with anti-*erb-B* serum. The precipitates were analysed on a 10% SDS-polyacrylamide gel, and the proteins visualized by fluorography. Exposure time 5 days. M denotes ^{14}C-labelled molecular weight standards from Amersham of 200,000, 94,000, 68,000, 45,000 and 30,000.

in which membrane populations the proteins resided, nor had any biosynthetic pathway for the processing of the *erb-B* glycoprotein been elucidated. We therefore extended this analysis by subfractionating the microsomes into rough endoplasmic reticulum, a smooth membrane fraction and plasma membranes. The localization of the *erb-B* proteins was also analysed following a pulse-label of 30 min and a chase of 2 h to monitor any redistribution of the various glycoproteins (Fig. 3). Initially, both gp66$^{erb\text{-}B}$ and gp68$^{erb\text{-}B}$ were located in the rough endoplasmic reticulum, as would be expected for intrinsic membrane glycoproteins (Fig. 3*a*). After 2 h, gp74$^{erb\text{-}B}$ was detected, but it was located exclusively in the plasma membrane-enriched fraction of the cell (Fig. 3*b*). In contrast, gp68$^{erb\text{-}B}$ was still mainly located in the rough endoplasmic reticulum fractions although a minor portion was also found in the plasma membrane-enriched fraction (Fig. 3*b*).

Monensin is a sodium ionophore which alters the intracellular transport of membrane glycoproteins[14]. Because gp74 seems to be the plasma membrane form of the *erb-B* gene, it was of interest to test whether monensin would inhibit its processing. A pulse-chase analysis performed in the presence and absence of 10 μM monensin revealed that in the absence of the ionophore the *erb-B* glycoproteins were processed to the gp74 form as usual (Fig. 4, tracks 1, 2). In contrast, although gp66$^{erb\text{-}B}$ was processed to gp68$^{erb\text{-}B}$ in the presence of monensin, no gp74$^{erb\text{-}B}$ was produced (Fig. 4, track 4). Therefore, monensin completely inhibits the processing of gp68$^{erb\text{-}B}$ to gp74$^{erb\text{-}B}$.

The production of antisera specific for the *erb-B* product allowed us to identify and characterize a previously unrecognized form of the *erb-B* glycoprotein, namely gp74$^{erb\text{-}B}$. Moreover, the observation that gp68$^{erb\text{-}B}$ is sensitive to endo-H whereas gp74$^{erb\text{-}B}$ is not, implies that the processing of gp66$^{erb\text{-}B}$ to gp68$^{erb\text{-}B}$ takes place in the rough endoplasmic reticulum whereas the processing of gp68$^{erb\text{-}B}$ to gp74$^{erb\text{-}B}$ probably occurs in some compartment of the Golgi complex. The sensitivity of the processing of gp68$^{erb\text{-}B}$ to gp74$^{erb\text{-}B}$ to the presence of 10 μM monensin, an ionophore which interferes with the passage of certain glycoproteins through the Golgi apparatus[14], is consistent with this hypothesis. Taken together with the cell fractionation studies, these data imply that gp74$^{erb\text{-}B}$ is the plasma membrane form of the *erb-B* gene product; a similar molecule has recently been identified by M. L. Privalsky and J. M. Bishop (personal communication).

With regard to the finding that the *erb-B* gene appears to be a truncated form of the growth factor receptor, most of the coding information removed comes from the amino-terminal end of the EGF receptor[9], which would include the EGF binding site. This helps to explain two recent observations. First, although there is near identity at the amino acid level between *erb-B* and EGF receptor, antisera against these two proteins do not cross-react (M.J.H., J. Downward and M. Waterfield, unpublished observations). However, this is not surprising as the anti-EGF receptor antibodies are directed against its amino terminus, which is missing from *erb-B*, and antibodies against the external domain of *erb-B* probably cannot gain access to this region in the EGF receptor because in *erb-B* the domain has a MW of only ~12,000 compared with 115,000 for the EGF receptor. Second, no kinase activity associated with *erb-B* has been detected in the standard immune complex assay[10]. This is consistent with its having lost the binding site for the growth factor, interaction with which would presumably stimulate activity. However, this does not mean that *erb-B* could not function as a kinase in certain specific conditions, and this enzymatic function may yet be involved in *erb-B*-induced cell transformation.

We thank Gay Kitchener for technical assistance, Drs J. A. Wyke and P. J. Enrietto for their critical comments and help with the manuscript, and Joyce Newton and Irene Esmond for typing the manuscript.

Molecular cloning of the whole biosynthetic pathway of a *Streptomyces* antibiotic and its expression in a heterologous host

F. Malpartida & D. A. Hopwood

John Innes Institute, Colney Lane, Norwich NR4 7UH, UK

The application of molecular cloning to antibiotic-producing microorganisms should lead to enhanced antibiotic productivity and to the biosynthesis of novel antibiotics by *in vitro* interspecific recombination[1,2]. To allow such approaches, the genes for antibiotic synthesis must be isolated, analysed and perhaps modified. Certain *Streptomyces* species produce nearly two-thirds of the known natural antibiotics[3]; the recent development of cloning systems in the genus[4–7] makes it possible to isolate and analyse *Streptomyces* genes. However, antibiotics are metabolites which require sets of several enzymes for their synthesis and attempts to isolate the corresponding genes have so far yielded clones carrying either individual genes of the set, or only incomplete gene sets[8–11]. We describe here the isolation of a large continuous segment of *Streptomyces coelicolor* DNA which apparently carries

the complete genetic information required for synthesis of an antibiotic, actinorhodin, from simple primary metabolites. Not only can the cloned DNA 'complement' all available classes of actinorhodin non-producing mutants of *S. coelicolor* but, on introduction into a different host, *Streptomyces parvulus*, it directs the synthesis of the antibiotic. The tendency for the genes for antibiotic synthesis to be clustered together on the chromosomes of *Streptomyces* species[12] and the availability of plasmid vectors which can carry stable inserts of DNA larger than 30 kilobase pairs (kb) and which can be introduced efficiently into *Streptomyces* protoplasts, suggest that the experiments described have general significance for this area of biotechnology.

Actinorhodin[13] belongs to a class of antibiotics named isochromanequinones which also includes granaticin[14], kalafungin[15] and the nanaomycins[16]. It is derived biosynthetically from acetate units (acetyl coenzyme A) through the polyketide pathway[17]. Rudd and Hopwood[18] isolated 76 actinorhodin non-producing mutants (*act*) and classified them into seven phenotypic classes, where each class represented lesions in a different biosynthetic step. Mutants in six of the classes co-synthesized actinorhodin in combination with other mutants, allowing a tentative biosynthetic sequence to be deduced, as follows:

I,III → VII → IV → VI → V → actinorhodin.

Mutants of class II failed to co-synthesize actinorhodin in any combination and perhaps included polar and regulatory mutations. At least one mutation of each class was mapped to the same segment of the *S. coelicolor* chromosome[18]. The actinorhodin system therefore offered the possibility of cloning a DNA fragment encoding a complete biosynthetic pathway provided that a suitable vector was available, with the eventual aim of analysing its physical organization and regulation.

Reconstruction experiments indicated that Act$^+$ colonies could be detected easily among a large number of *act* colonies by the formation of the blue diffusible actinorhodin when grown on R2YE medium[6]. 'Complementation' of an *act* mutant, detected by restoration of the pigmented phenotype, was therefore used as the screen for desired clones. A mutant of *act* class V, blocked in a late step of the biosynthesis (and also carrying a *red* mutation to abolish production of the other pigment, undecylprodigiosin[19]) was used as the recipient for cloned DNA from the wild-type *act*$^+$ strain.

The plasmid SCP2*, a 31-kb sex factor of *S. coelicolor*[20,21], has recently been developed into a series of cloning vectors by deletion of dispensable DNA and by addition of drug resistance markers[22]. One such vector is pIJ922 (25 kb) which contains a gene for thiostrepton resistance (*tsr*) from *Streptomyces azureus*[6] and has single sites for several restriction enzymes, including *Bam*HI, within a non-essential region. DNA of pIJ922, purified by CsCl–ethidium bromide density gradient centrifugation[21], after alkaline lysis[23], was digested with *Bam*HI. After phenol extraction, 0.5 μg of the linearized plasmid was mixed with 5 μg of chromosomal DNA from an *act*$^+$ *S. coelicolor* strain which had been partially digested with *Mbo*I and size-fractionated in a sucrose density gradient[24] to give fragments in the size range 15–30 kb. The DNA mixture, after ethanol precipitation, was dissolved in T4–DNA ligase buffer and ligated[25] at a final DNA concentration of 50 μg ml^{-1}. The ligated DNA was re-precipitated and dissolved in 25 μl TE (10 mM Tris-HCl, 1 mM EDTA, *p*H 8). An aliquot containing 4.4 μg of ligated DNA was used to transform[25] protoplasts of *S. coelicolor* SCP2$^-$ strain JF4 (*proA1 argA1 cysD18 strA1 act109 (V) redE60*)[8]. After allowing 20 h for phenotypic expression of thiostrepton resistance, the R2YE regeneration medium plates were overlaid with soft nutrient agar (Difco) containing thiostrepton to give a final concentration in the entire plates of 50 μg ml^{-1}.

Two blue colonies (presumptive clones) were detected among a total of ~8,000 transformants growing on 20 plates. Isolation of CCC DNA from the colonies revealed recombinant plasmids (named pIJ2300 and pIJ2301); each was introduced by transformation into *act* mutants of each of the seven classes, with the results shown in Table 1. pIJ2300 complemented all classes except VI, while pIJ2301 complemented classes V, VI and VII. Restriction maps of the plasmids revealed inserts of 34 and 16 kb in pIJ2300 and pIJ2301 respectively, with an apparently overlapping region of 12 kb (Fig. 1).

The entire insert of pIJ2300 was bounded by *Bam*HI sites. Moreover, preliminary subcloning experiments showed that class VI mutations could be complemented by a 4.5-kb *Bam*HI fragment uniquely present at the left-hand end of pIJ2301 (Fig. 1) and presumably the most distal region carrying biosynthetic genes. This suggested a strategy for constructing a single clone able to complement all available *act* mutants, and perhaps containing the entire chromosomal region responsible for actinorhodin biosynthesis. A mixture of pIJ2300 partially digested with *Bam*HI and pIJ2301 completely digested with *Bam*HI (plus *Eco*RI to prevent re-formation of pIJ2301) was ligated and used to transform protoplasts of strain JF3 (*act* class

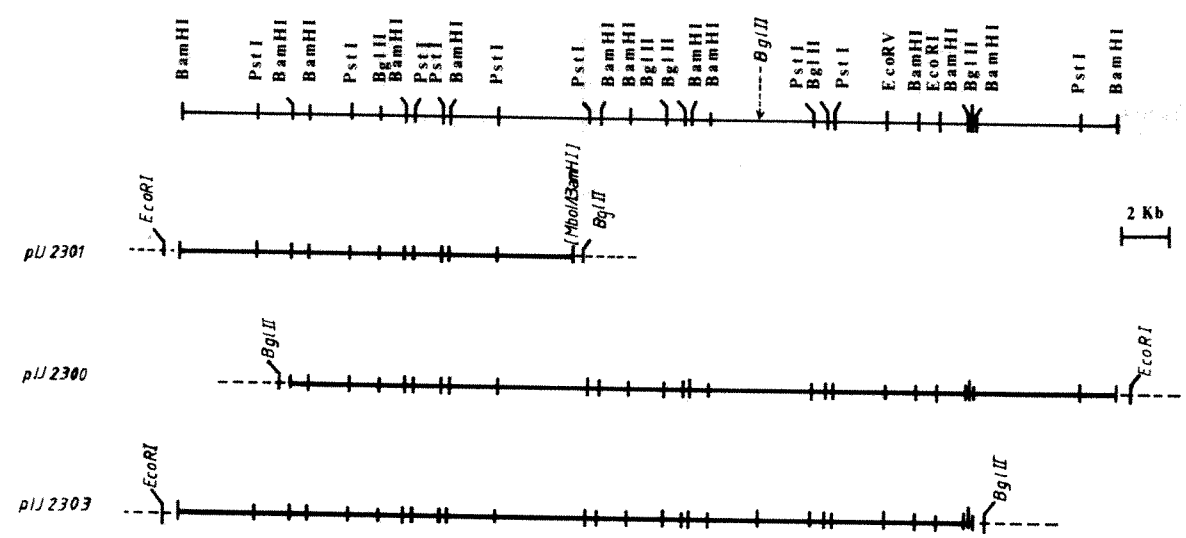

Fig. 1 Comparative restriction maps of *act*$^+$ clones pIJ2301, pIJ2300 and pIJ2303. The maps of pIJ2300 and pIJ2303 were derived from the maps of overlapping fragments subcloned into SCP2*-derived vectors. In addition to loss of a 6-kb *Bam*HI fragment from the right-hand end of pIJ2300, pIJ2303 carries a new *Bgl*II site (arrow). From the results of subcloning experiments, this discrepancy does not affect the ability of pIJ2303 to 'complement' all of the *act* mutants tested, and may be explicable by homologous recombination between pIJ2300 (with wild-type DNA) and the chromosome of the *act* mutant in *S. coelicolor* JF4, giving rise to a heterogeneous plasmid population. Dashed lines indicate pIJ922 vector DNA, with the *Eco*RI and *Bgl*II sites shown for orientation.

VI). Of 20 blue transformants, one carried a plasmid (pIJ2303) that complemented strongly *act* mutants of all seven classes. The restriction map of pIJ2303 (Fig. 1) demonstrated insertion of the required 4.5-kb *Bam*HI fragment from pIJ2301 at the left end of the pIJ2300 insert and in the original orientation of pIJ2301. At the opposite end, pIJ2303 showed deletion of a 6-kb *Bam*HI fragment present in pIJ2300, but evidently this was not required for complementation of any of the available *act* mutants.

To determine whether pIJ2303 carried the entire set of *act* biosynthesis genes, pIJ2300, pIJ2301 and pIJ2303 were introduced by transformation into genetically marked strains of *S. parvulus* ATCC 12434. This strain does not produce actinorhodin and is not a close relative of *S. coelicolor* A3(2) as judged either by conventional taxonomy or by DNA–DNA hybridization[26]. It is, however, a host for SCP2 plasmids. Only those transformants that grew on R2YE plates containing thiostrepton and which carried pIJ2303 were blue (Table 1). Thin-layer chromatography of methanol extracts[19] of the *S. parvulus* host cultures and the same strains containing each of the three recombinant plasmids showed the presence of a blue pigment only in clones carrying pIJ2303. This blue pigment co-migrated with a corresponding pigment in extracts from *act*$^+$ but not *act* *S. coelicolor* cultures and had acid–base indicator properties characteristic of actinorhodin. The amounts of the blue pigment in extracts of *S. parvulus* carrying pIJ2303 were similar to those of wild-type *S. coelicolor*. This result suggests that the entire DNA sequence corresponding to the structural genes for actinorhodin biosynthesis is carried by pIJ2303.

The success of the cloning experiments reported here may well have depended on the use of a low-copy number vector (the estimated copy number of the parent SCP2 is one per chromosome of *S. coelicolor*[21]) so that the recipient strain is not likely to be placed at a disadvantage by possible high-level expression of physiologically active gene products. This view is supported, though not proved, by our failure to isolate any Act$^+$ clones in extensive trials with the high-copy number vector pIJ702 (ref. 27) despite the fact that this vector has proved convenient for the cloning of comparatively short segments of DNA carrying other genes[8,28]. Vectors such as pIJ922, and other SCP2* derivatives recently developed by Lydiate[22], appear to be particularly suitable for the stable maintenance of large fragments of cloned DNA. Moreover, the large recombinant plasmids are readily isolated from *Streptomyces* cultures[23], and transform *Streptomyces* protoplasts efficiently. Thus pIJ2300, of 59 kb, yielded 10^6 transformants per μg of DNA in optimal conditions, compared with 10^7 for the pIJ922 vector.

As the entire carbon skeleton of actinorhodin is derived from acetate[17], no specialized primary metabolites are required for its biosynthesis, a factor which may have contributed to the efficient expression of pIJ2303 in *S. parvulus*, leading to production of actinorhodin. Many important antibiotics are also polyketides—including the macrolides, tetracyclines and rifamycins. It is generally accepted that the primary carbon skeletons of polyketides are assembled on multienzyme complexes (or multifunctional enzymes) analogous to fatty acid synthetases[29], and the genes or gene clusters that encode polyketide synthetases may have had a common evolutionary origin, perhaps shared with fatty acid synthetases. Thus, the availability of clones carrying the presumptive actinorhodin 'synthetase' may be useful, not only as a model system, but possibly as DNA probes for the isolation of other antibiotic synthetases.

We thank Derek Lydiate for making available his unpublished results and for vector plasmids, Jerry Feitelson for helpful discussions, and Mervyn Bibb, Keith Chater and Tobias Kieser for useful comments. F.M. acknowledges a post-doctoral stipend from the Juan March Foundation of Madrid.

Ha-*ras* oncogenes are activated by somatic alterations in human urinary tract tumours

Jun Fujita*, Osamu Yoshida†, Yasuhito Yuasa*, Johng S. Rhim*, Masakazu Hatanaka‡ & Stuart A. Aaronson*§

* Laboratory of Cellular and Molecular Biology, National Cancer Institute, Building 37, Room 1A07, Bethesda, Maryland 20205, USA

DNA-mediated gene transfer (transfection) studies using NIH 3T3 cells as recipients have demonstrated the presence of transforming genes (oncogenes) in diverse human tumours (for reviews see refs 1, 2). A large proportion of oncogenes so far detected by DNA transfection are related to the Ha-*ras onc* gene of Harvey (and BALB) murine sarcoma viruses (MSV)[3–6], Ki-*ras*, the oncogene of Kirsten MSV[3,7,8], and a third member of the *ras* gene family, N-*ras* (refs 8–12). Individual tumours of many different organs

§ To whom correspondence should be addressed.

have been associated with the activation of members of the *ras* gene family. We now present the first systematic survey of human urinary tract tumours processed immediately after surgery, as well as normal tissues from the same patients, to detect the presence of such genes. We demonstrate activation of Ha-*ras* as an oncogene in around 10% of randomly selected urinary tract tumours as well as direct evidence that oncogene activation is the result of a somatic event which is selected for within the tumour cell population.

Urinary tract carcinoma, at any site from renal pelvis to urethra, is considered to be a gross manifestation of a generalized neoplastic change of its epithelium, the urothelium. Multiple bladder carcinomas are not uncommon at cystoscopy and detailed histological examination of surgical specimens from patients with carcinomas of the bladder, renal pelvis and ureter has revealed a high incidence of neoplastic and preneoplastic lesions at sites other than the actual tumour[13,14]. To survey for oncogenes detectable by transfection analysis, high molecular weight DNA in sufficient quantity for analysis was obtained from 23 out of 32 randomly selected consecutive specimens of urinary tract tumours. The tumours were transitional cell carcinomas except for one adenocarcinoma.

Transforming activity was observed with two tumours. These two patients (JPT26 and JBT44) had no special features in terms of occupation, past history, or clinical or pathological characteristics of the tumour[15]. Moreover, there was no apparent correlation between the presence of an active oncogene and the degree of invasiveness of the tumours analysed. In each case, transforming activity survived a second cycle of transfection using high molecular weight DNAs of individual first-cycle NIH 3T3 transfectants (Table 1). Southern blotting analysis showed the presence of human repetitive sequences in all first- and second-cycle transfectants, implying that the foci observed were induced by human DNA (data not shown).

DNAs from JPT26- and JBT44-induced foci were hybridized with nick-translated probes specific to each of the *ras* oncogenes. Neither human Ki-*ras* nor N-*ras* probes detected DNA fragments other than the endogenous bands (data not shown). However, when *Bam*HI-digested transfectant DNAs were analysed for Ha-*ras*-related sequences, all tested JPT26 and JBT44 transfectants exhibited an additional 7-kilobase pair (kbp) DNA fragment (Fig. 1*a*). These findings identified the oncogene in each tumour as an activated allele of the Ha-*ras* proto-oncogene.

Accumulating evidence indicates that the major sites for the genetic lesions responsible for activation of *ras* oncogenes in human tumours are localized to positions 12 and 61 in their coding sequences[6,16–21]. An alteration at position 12 in human Ha-*ras* leads to loss of a restriction site for *Hpa*II–*Msp*I digestion, thus providing a means of molecular diagnosis of lesions at this position[22]. As Fig. 1*b* shows, DNA from JPT26 and JBT44 transfectants demonstrated a 355-base pair (bp) band (lanes 1 and 2, respectively) like that observed with human placenta DNA (lane 3), while the T24 transfectant DNA yielded the expected 411-bp band (lane 4). These results indicated that neither the JPT26 nor JBT44 oncogenes had undergone mutations affecting the 12th amino acid of its p21 coding sequence.

The recognition sequence for *Bst*NI is $CC^{A}_{T}GG$, whereas the normal sequence encompassing position 61 in the Ha-*ras* proto-oncogene is CCAGG (Fig. 2)[23,24]. Thus, any alteration in the sequence other than A to T would be expected to eliminate this *Bst*NI recognition site. As Fig. 2 shows, the electrophoretic mobilities of two *Bst*NI-digested DNA fragments hybridizing to the Ha-*ras* *Kpn*I–*Nco*I probe in a representative JBT44 transfectant (lane 4) were not distinguishable from those of a T24 transfectant, possessing a position 12 lesion (lane 1)[16–18]. The 158-bp band corresponded to the larger fragment observed with an intact *Bst*NI site at position 60–62. A transfectant containing the Hs242 oncogene, whose corresponding sequence at position 61, CCTGG (ref. 6), would also be recognized by *Bst*NI, demonstrated an identical pattern of DNA fragments (Fig. 2, lane 2). In contrast, a JPT26 transfectant DNA exhibited a different hybridizing DNA fragment, whose 173-bp size corresponded to that expected in the absence of a *Bst*NI cleavage site at position 60–62 (lane 3). Thus, these results established that the oncogene from patient JPT26 had suffered a genetic lesion affecting codons 60, 61 or 62.

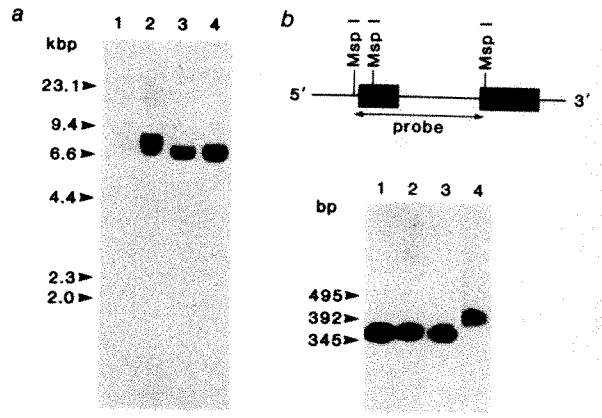

Fig. 1 Detection and identification of the human urothelial carcinoma transforming genes and their *Msp*I sensitivity at codon 12. 20 μg of high molecular weight DNA were digested with *Bam*HI (column *a*) or with *Msp*I and *Hpa*II (column *b*), electrophoresed in 1.2% or 2.0% agarose gel, respectively, transferred to nitrocellulose paper and hybridized as described previously[6,25]. *a*, DNAs from NIH 3T3 cells (lane 1), human placenta (lane 2), as well as representative first-cycle transfectants of JPT26 (lane 3) and JBT44 (lane 4) tumours were hybridized with the 6.6-kbp *Bam*HI fragment of the T24 oncogene, p24-c3 (ref. 17). In these conditions, the mouse endogenous 3.5-kbp Ha-*ras*-related fragment was not observed. Co-electrophoresed DNA fragments of *Hin*dIII-digested λc1857 DNA served as molecular weight standards. *b*, The upper panel shows the *Msp*I restriction map of the human Ha-*ras* proto-oncogene. The two solid boxes indicate the first and second exons from the 5′ to 3′ direction. In the lower panel, DNAs from representative first-cycle transfectants of JPT26 (lane 1), JBT44 (lane 2) and T24 (lane 4) tumours, as well as human placenta DNA (lane 3) were hybridized with the T24 *Msp*I fragment shown by the arrow in the upper panel. Co-electrophoresed DNA fragments of *Hin*cII-digested ΦX174RF DNA served as molecular weight standards. The 56-bp fragment was not apparent in these experimental conditions.

Table 1 Transforming activity of DNA from human urinary tract tumours

Donor DNA	Total no. foci/total DNA tested (μg) Primary	Secondary
T24 bladder carcinoma	85/400	—
JPT26 renal pelvic carcinoma*	8/320	37/240
JBT44 bladder carcinoma†	15/320	28/240

Human tumours were minced with scalpels within 4 h of surgical removal, incubated for 3 h at 37 °C with 200 μg ml^{-1} of proteinase K in the presence of 0.5% SDS and 10 mM EDTA, extracted with phenol and precipitated with ethanol. High molecular weight DNA was further purified by treatment with RNase, proteinase K and extracted with phenol/chloroform. These DNAs, as well as DNAs from representative first-cycle NIH 3T3 transfectants, were used to transfect onto NIH 3T3 cells by the calcium phosphate precipitation technique, as described previously[6]. Foci of transformed cells were scored at 21 days. Twenty-three tumours, including four non-invasive tumours, were tested. Two of these were cytological grade 1, 11 were grade 2 and 10 were grade 3 (ref. 15). In 10 cases, bladder tumours were multiple. Eight patients had a previous history of bladder tumours.

* JPT26, a 33-yr-old male who had the right kidney and ureter removed for a papillary non-invasive transitional cell carcinoma, grade 2 of the renal pelvis.

† JBT44, a 44-yr-old male who underwent transurethral resection of recurrent multiple transitional cell carcinomas of the bladder which were grade 2 and invaded the submucosa (P1).

The upper panel shows the *Bst*NI restriction map of the human Ha-*ras* proto-oncogene. The two solid boxes represent the second and third exons from the 5′ to 3′ direction. ●, *Bst*NI cleavage sites: *, the *Bst*NI site encompassing codon 61. The nucleotide sequence surrounding this site is also shown. The numbers below the sequence indicate the amino acid codon number. The lower panel shows Southern blotting analysis of DNAs from representative NIH 3T3 transfectants of T24 (lane 1), Hs242 (lane 2), JPT26 (lanes 3, 6) and JBT44 (lane 4) tumours as well as JPT26 primary tumour (lane 5) and JPT26 normal peripheral leukocytes (lane 7). DNAs were digested with the restriction endonuclease *Bst*NI, electrophoresed in a 4% agarose–50% formamide gel[26], blotted to nitrocellulose paper and hybridized with the *Kpn*I–*Nco*I fragment of the human Ha-*ras* proto-oncogene as shown in the upper panel. Twice as much DNA (100 μg) was used in lane 5 as in the other lanes. The variable detection of the 128/123-bp DNA fragment (compare lanes 3 and 6) with the same JPT26 transfectant DNA reflects variability in the efficiency of transfer of low molecular weight DNA species to the nitrocellulose paper. Co-electrophoresed DNA fragments of *Hinc*II-digested ΦX174RF DNA served as molecular weight standards.

The availability of normal peripheral blood leukocytes from patients JPT26 and JBT44 made it possible to assess whether normal tissues from these patients contained normal or activated Ha-*ras* alleles. DNAs from these normal cells were assayed for transforming activity in the NIH 3T3 transfection assay. No focus-forming activity was detectable with either DNA, in conditions in which both tumour cell DNAs readily registered as positive (data not shown). When DNAs from the JPT26 primary tumour and normal peripheral blood leukocytes were analysed by a molecular genetic approach (Fig. 2), the Ha-*ras* *Kpn*I–*Nco*I probe hybridized to *Bst*NI-digested DNA fragments of 173 and 158 bp as well as to the 128/123-bp species in DNA of the primary JPT26 tumour (Fig. 2, lane 5). In contrast, normal peripheral blood leukocytes from patient JPT26 (lane 7) demonstrated only the 158-bp hybridizing DNA fragment. The 173-bp fragment specific for the altered Ha-*ras* allele present in the JPT26 transfectant (lanes 3, 6) was not detected in the normal cells. These results established that the altered Ha-*ras* allele was present in the JPT26 tumour but not in normal tissues from the same patient.

Transforming genes were detected by transfection analysis in 2 of 23 randomly selected primary human tumours of the urothelium. In both cases, Ha-*ras* oncogenes were identified as the source of transforming activity. Neither oncogene was activated by a lesion at position 12 in the coding sequence, consistent with other studies indicating that position 12 lesions in Ha-*ras* are not commonly detected in primary human tumours[22]. We demonstrated a genetic alteration(s) within codon(s) 60, 61 or 62 of the Ha-*ras* coding sequence of the JPT26 tumour by a *Bst*NI restriction site polymorphism. Since position 61 is a major 'hot spot' for activation of *ras* oncogene in human tumours[6,21], it is likely that the genetic alteration detected at this position of the JPT26 oncogene coding sequence is responsible for its activation as a transforming gene.

It is of critical importance to establish the direct relevance of an oncogene detected in a human tumour to the neoplastic process affecting that tumour cell. In the present studies, normal cell DNA from neither of the patients whose tumours contained Ha-*ras* oncogenes possessed a transforming gene detectable by transfection analysis. By restriction enzyme analysis, it was possible to obtain direct biochemical evidence that the genetic lesion in the JPT26 oncogene was not present in normal cellular DNA of this same patient. These findings establish that this genetic alteration is the result of a somatic event which must be powerfully selected for within the tumour and, thus, likely to contribute to its development.

Our results also suggest that that Ha-*ras* oncogenes are more commonly activated in urinary tract tumours than are N- or Ki-*ras* genes. This is in contrast to haematopoietic tumours, where N-*ras* appears to be the most frequently activated *ras* oncogene[8,12], or lung and colon carcinoma where the Ki-*ras* oncogene appears to predominate[3,7,19,20]. The frequency at which oncogenes were detected is likely to be an underestimate due to the inherent insensitivity of the transfection assay. Single base changes at either position 12 or 61 in the Ha-*ras* coding sequence will lead to loss of *Msp*I or *Bst*NI sites for 6/6 and 7/8 possible amino acid substitutions, respectively. Thus, a systematic survey of urinary tract carcinomas for these point mutations as well as for amplification or other rearrangements using biochemical approaches may provide a more accurate estimate of the frequency at which Ha-*ras* is activated as an oncogene in these naturally occurring human malignancies.

We thank doctors at our affiliated hospitals for help in obtaining tissues; N. Kobayashi, K. Mori, S. Srivastava and S. R. Tronick for helpful discussion; and H. Fuhrer for photographic work. Evolution of phosphofructokinase—gene duplication and creation of new effector sites

Roger A. Poorman*, Anne Randolph†‡, Robert G. Kemp† & Robert L. Heinrikson*

* Department of Biochemistry, The University of Chicago, 920 E. 58th Street, Chicago, Illinois 60637, USA
† Department of Biological Chemistry and Structure, The Chicago Medical School, North Chicago, Illinois 60064, USA

Phosphofructokinases (PFK; EC 2.7.1.11) are tetrameric enzymes that have a key role in the regulation of glycolysis[1]; as such, they are subject to allosteric activation and inhibition by various metabolites[2]. Eukaryotic PFKs are about twice the size of prokaryotic enzymes and are regulated by a wider repertoire of effectors: for example, the subunit molecular weights of rabbit muscle (RM) PFK and *Bacillus stearothermophilus* (Bs) PFK are 82,000 and 36,000, respectively. Both enzymes are activated by ADP (or AMP), but RM-PFK is also activated by fructose bisphosphates (FBP) and inhibited by ATP and citrate. This, together with other evidence, has led to speculation that mammalian PFKs have evolved by duplication of a prokaryotic gene[3–5], although previous peptide analysis[6] failed to reveal internal homology in RM-PFK. Here we demonstrate clear homology among the N- and C-halves of RM-PFK and Bs-PFK, thus establishing an evolutionary relationship by series gene duplication and divergence. Furthermore, detailed knowledge of the Bs-PFK structure provides the basis for inferences concerning the structural organization of RM-PFK and the evolution of new effector sites in the enzyme tetramer.

The nearly complete amino acid sequence of RM-PFK is given in Fig. 1, together with that of Bs-PFK[7]. Strong homology is observed among the N- and C-halves of the RM-PFK molecule and Bs-PFK. The average minimum base differences per codon[8], calculated between the halves of the RM-PFK subunit and between each half of RM-PFK and the bacterial PFK are as follows: Bs-PFK versus N-half of RM-PFK, 0.82 (319 residues compared); Bs-PFK versus C-half of RM-PFK, 0.93 (289 residues compared); and N-half versus C-half, 1.02 (329 residues compared). The respective identities for each comparison are 44%, 34% and 32%. These numbers substantiate a significant degree of homology among all three sequences; the N-half of RM-PFK is especially homologous to the bacterial enzyme. Insertions in the RM-PFK halves are easily accommodated at the surface[9,10], and need not alter the basic architectural theme of Bs-PFK. Clearly, there is extensive internal homology in the RM-PFK subunit, and the mammalian enzyme arose by series gene duplication of an ancestral message related to that of Bs-PFK.

The evolution of proteins proceeds with conservation of three-dimensional structure, despite wide-ranging diversification of amino acid sequence[11,12]. Therefore, our sequence data represent strong evidence that the N- and C-halves of RM-PFK and the Bs-PFK subunit share a similar conformation. It follows that the tertiary structure of the RM-PFK subunit will be represented by two 'super' domains, each closely resembling the structure of the Bs-PFK monomer, joined by a connecting peptide of about 30 residues (Lys 320, N-half to Ala 5, C-half; Fig. 1). The tertiary structure of Bs-PFK and the location of catalytic and effector sites in the enzyme have been described by Evans and co-workers[9,10], and two schematic views of subunits in the Bs-PFK tetramer as related by the *x*- and *z*-dyad axes are shown in Fig. 2. Clearly, the N- and C-termini of both pairs of subunits are close enough to be joined covalently by the length of connecting peptide available. Therefore, the halves of the RM-PFK monomer could be disposed spatially as *z*- or *x*-dyad-related pairs of subunits in Bs-PFK (Fig. 2*a* and *b*, respectively). We

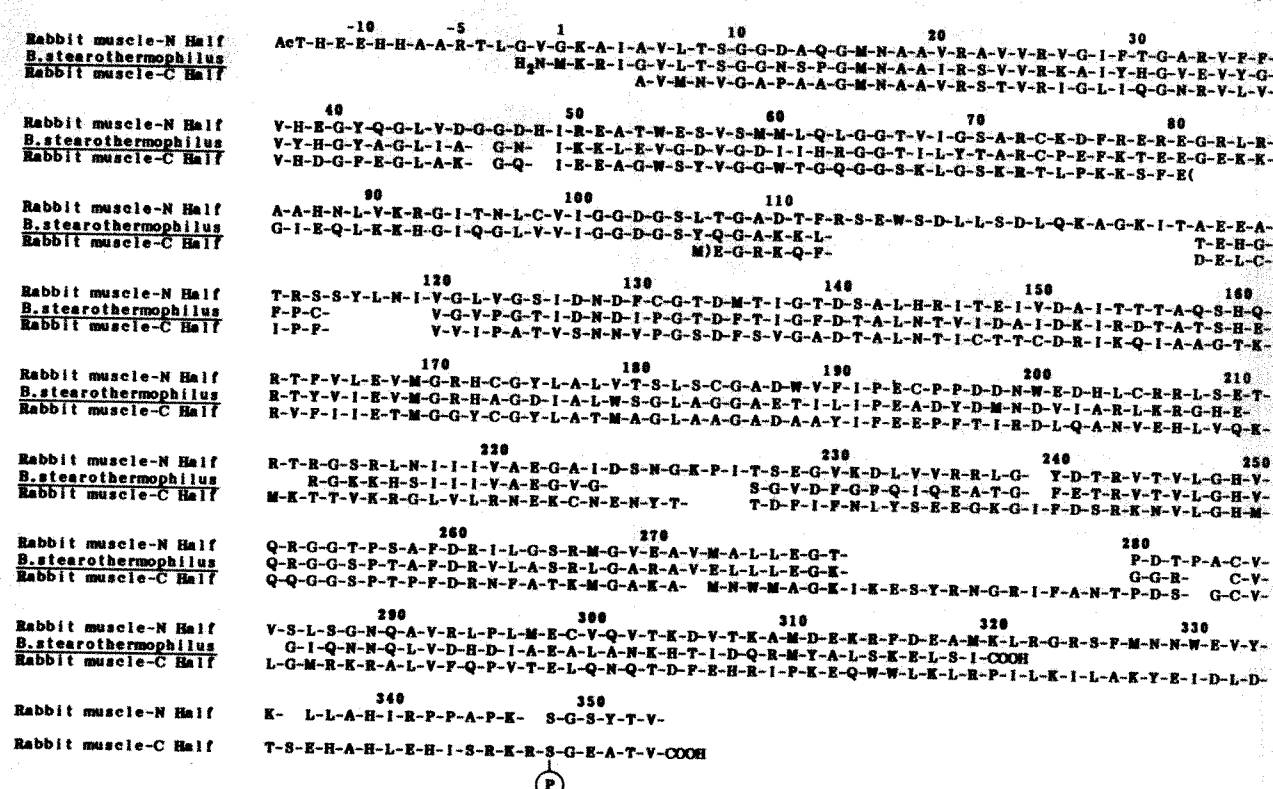

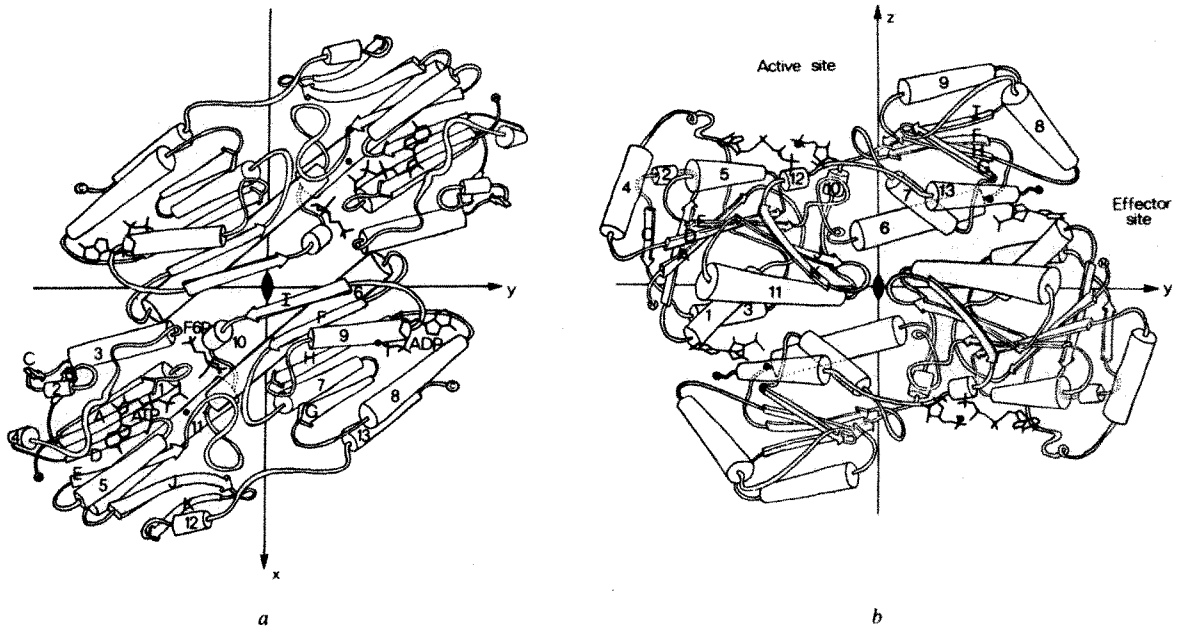

Fig. 1 The amino acid sequences of the N- and C-halves of RM-PFK compared with that of Bs-PFK. Numbering of residues is based on the Bs-PFK sequence[7] revised by crystallographic analysis[10] as follows: the tripeptide G–V–Y has been inserted after Y-35. In addition, V-43 and L-225 have each been changed to G; S-264 and A-265 have been reversed (P. R. Evans, unpublished). After residue 319, numbering is based on residues in the C-half. The Bs-PFK sequence is placed between the RM-PFK halves to emphasize homology. V-353 (N-half) is peptide-bonded to A-5 in the C-half of RM-PFK. S-348 (C-half) is the site of phosphorylation[20]. The region enclosed in parentheses (residues 81–106, C-half) is uncertain at present. Overlaps between N-half residues 50–51, 145–146, 162–163, 261–262 and 266–267 are based on homology and have yet to be proven.

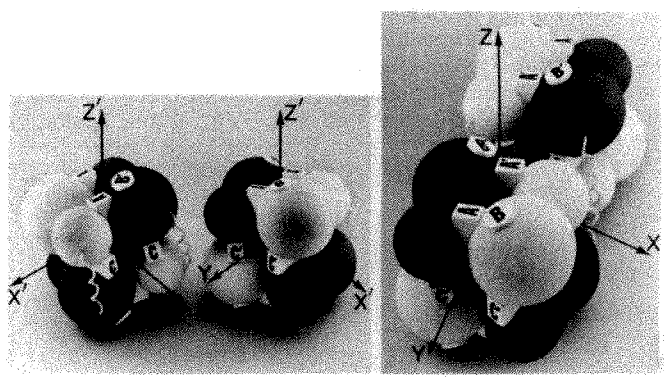

a *b*

Fig. 2 Schematic views of two subunits in the Bs-PFK tetramer: *a*, viewed along the *z*-axis; *b*, viewed along the *x*-axis. In each case, the other two subunits lie behind those shown. β-Strands are indicated by arrows (A–K) and α-helices by cylinders (1–13). The substrates ATP and F6P are shown in the active site and the activator ADP in the effector site. (Taken from Evans *et al.*[10].)

prefer the alignment depicted in Fig. 2*b*, giving an RM-PFK subunit in which the halves are related by the *x*-dyad. This preference is based on internal helical packing interactions which would stabilize the subunit, and the fact that cooperativity in binding of fructose 6-phosphate (F6P) occurs between *z*-dyad-related subunits in Bs-PFK[10]. Moreover, the dimer is thought to be inactive[13,14], as would be predicted by disruption of the F6P binding site. Fructose bisphosphate, like F6P, contributes to stabilization of the tetramer[14,15], and our view is that the FBP site is a mutated F6P site lying between the same *z*-dyad pair (see below). Covalent joining of the *z*-dyad subunits would create cooperative allosteric and active sites within, rather than between, subunits in RM-PFK, and we consider this mode of attachment to be less likely.

Speculation concerning the quaternary structural organization of RM-PFK is based on the structural relationship to Bs-PFK and the known D2 symmetry of the mammalian tetramer[16]. It is possible to bring two large RM-PFK subunits into juxtaposition to give a mammalian dimer equivalent to the Bs-PFK tetramer. Two views of such a dimer are represented by the models in Fig. 3*a*: here, the N- and C-halves of each subunit (light and dark, respectively) are joined by a connecting peptide (indicated by a helical strand of wire). The large and small lobes in each half represent the domains in Bs-PFK[9]; thus, the equivalent array of domains is preserved in our model of the RM-PFK dimer. In order to generate a tetramer having D2 symmetry, RM-PFK dimers must be brought together along the *y*-axis with all connecting peptides either on the outer or inner faces. Our preference for placing all the connecting peptides at the dimer interface (Fig. 3*b*) is supported by results from limit proteolysis. Treatment of native RM-PFK with subtilisin yields an inactive tetramer in which the N-terminal 50–60 residues have been removed[17], suggesting that the N-half of each subunit is pointing outwards and is susceptible to proteolysis, and that the intersubunit forces maintaining the tetramer are still intact. These forces may well involve interactions among the connecting peptides. We have also shown that of several enzymes tested, only trypsin and endoproteinase Lys-C cleave in the connecting peptide region. This argues in favour of our proposed shielded and symmetrical arrangement of these segments in the tetramer.

Crystallographic analysis of Bs-PFK has revealed the active site regions for binding the substrates F6P and ATP, and an allosteric site for the activator, ADP. These sites were designated

a *b*

Fig. 3 Models indicating our proposed structural organization of RM-PFK. Two views of the dimer and the tetramer are shown in *a* and *b*, respectively. The N- and C-halves of each subunit are light and dark, respectively, and connecting peptides are represented by helical strands of wire. Each side-by-side dimer is equivalent to the Bs-PFK tetramer[9], and the dimers are brought together to give a tetramer with D2 symmetry (*b*) in which all four connecting peptides are localized at the interface. The models also predict the location of sites for binding F6P (A), FBP (A'), ATP substrate (B), ADP activator (C), and ATP inhibitor (C'). Only one of the four C sites is visible in *b*; the other three are in corresponding positions at the interface. The remaining two C' sites are at the opposite end of the tetramer.

A, B, and C, respectively[9]. Sites which we believe have mutated from A and C are denoted A' and C' (see Fig. 3). Doubling of the Bs-PFK structure should give a RM-PFK tetramer with eight active sites and eight allosteric sites. Equilibrium binding studies have revealed, however, that there are only four catalytic sites in RM-PFK[18,19], and the greater number of effectors regulating the mammalian enzyme suggests that some catalytic and allosteric sites in the eukaryotic PFKs may have differentiated to provide new functionalities in these enzymes. Evidence in support of this notion derives from our comparative sequence analysis (Fig. 1). Homology in the vicinity of Asp-127 in Bs-PFK, a residue involved in F6P binding[10], is clearly evident in the N-half of RM-PFK but not in the C-half, where the corresponding residue is a serine. We believe, therefore, that the F6P site (A) is conserved as part of the catalytic apparatus of RM-PFK,

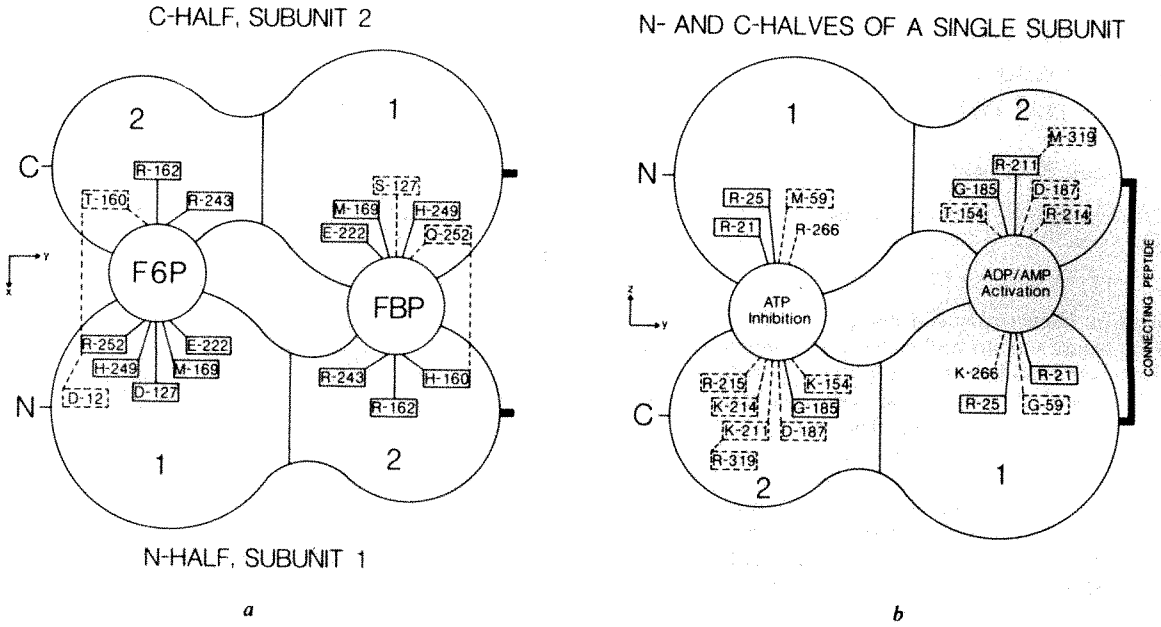

Fig. 4 Location of substrate and effector sites in RM-PFK based on crystallographic analysis of Bs-PFK and comparative sequence analysis. Residues enclosed in solid boxes are identical to those at corresponding positions in Bs-PFK; those enclosed in dotted boxes are different. *a*, View along the *z*-dyad axis of the N- and C-halves of two adjacent subunits which together define sites for cooperative binding of F6P (site A) and FBP (site A'). Dotted lines between residues indicate possible hydrogen bonds[10]. *b*, View along the *x*-dyad axis of the halves of a single RM-PFK subunit in which residues presumed to be involved in binding ADP activator (C site) and ATP inhibitor (C' site) are noted (compare with Fig. 3). The solid bar labelled 'connecting peptide' represents the covalent bridge between the halves related by the *x*-dyad axis (Figs 2*b*, 3). Position 266 is not boxed because its possible involvement in ligand binding was suggested by chemical modification[21] and not by crystallography.

but that its counterpart in the C-half (A') now binds FBP (Fig. 4*a*). This seems reasonable as Asp 127 is probably required as a base catalyst acting to increase the nucleophilicity of the O-1 hydroxyl of F6P for attack on the γ-phosphate of ATP. Its presence would cause electrostatic repulsion of FBP; replacement of Asp 127 by Ser in the new A' site would remove this negative charge and provide more room for binding of the fructose 1,6- and 2,6-bisphosphates which are known to compete for a common site[15]. Thus, it is reasonable to suggest that the structural change leading to replacement of the catalytically essential Asp 127 has led to loss of a catalytic site (A) and creation of an allosteric site for FBP activation (A').

The arguments thus far account for the presence of four catalytic sites in the RM-PFK tetramer, and provide evidence as to how four new sites for binding FBP may have arisen in evolution. Furthermore, the cooperativity in binding of F6P and FBP is in keeping with our model of the tetramer where binding is between subunits (Figs 3*b*, 4*a*). The case is not so clear-cut for a possible mutation of the ADP activation site (C) to a new site for ATP inhibition (C'). Here the inferences rest more on results from limit digestion with subtilisin[17] than on comparative sequence analysis. Although the subtilisin-treated RM-PFK tetramer retains the ability to bind FBP and ADP, it no longer binds ATP at the inhibition site, nor F6P. These results for a tetrameric PFK derivative having degraded N-termini are consistent with our location of F6P and FBP sites, A and A', respectively (Figs 3*b*, 4*a*). They also lend credence to the idea that the ADP activation site (C) involves residues in each subunit that are protected from the proteinase, that is, in the middle or C-terminal regions far enough removed from the N-terminal segment (Fig. 4*b*). Accordingly, the ATP inhibition site (C' in Fig. 3) could be a mutated ADP activation site, composed of N-terminal amino acid side chains, that is destroyed by subtilisin (Fig. 4*b*). We suggest, therefore, that RM-PFK has retained four of the ADP activation sites of its bacterial progenitor, but that it has gained, through evolution of the remaining four possible ADP sites, four new ATP inhibition sites per tetramer.

Thus, our model of RM-PFK predicts that the N- and C-halves of each subunit in the tetramer are equivalent in tertiary and quaternary structural organization to the subunits in a hypothetical Bs-PFK octamer composed of two bacterial enzyme tetramers joined end-to-end along the *y*-axis. The A sites for F6P binding and the C' ATP inhibition sites are exposed and comprise side chains from residues in the N-terminal regions, while the A' and C sites which bind FBP and ADP activators, respectively, are made up of residues that are internal, or C-terminal in the subunits which are protected from digestion with subtilisin. At present we have no crystallographic data pertaining to the subunit organization or functional sites of RM-PFK. However, our results obtained by comparative sequence analysis, together with findings from X-ray crystallography of Bs-PFK, chemical modification studies, kinetic analysis and limit proteolysis, can be interpreted to give a unified tentative working model of the mammalian enzyme tetramer which can be addressed experimentally.

We thank Dr Lawrence Foe for helpful discussions in regard to the quaternary organization of RM-PFK. This work was supported by grants AM-19912 and 26564 from the USPHS. A.R. was supported by a postdoctoral fellowship from The Chicago Heart Association.

Successive incorporation of force-generating units in the bacterial rotary motor

Steven M. Block & Howard C. Berg

Division of Biology 216–76, California Institute of Technology, Pasadena, California 91125, USA

Mot **mutants of *Escherichia coli* are paralysed: their flagella appear to be intact but do not rotate[1]. The *motA* and *motB* gene products are found in the cytoplasmic membrane[2]; they do not co-purify with flagellar basal bodies isolated in neutral detergents[1]. Silverman *et al.* found that *mot* mutants could be 'resurrected' through protein synthesis directed by λ transducing phages carrying the wild-type genes[2]. Here, we have studied this activation at the level of a single flagellar motor. Cells of a *motB* strain carrying plasmids in which transcription of the wild-type *motB* gene was controlled by the *lac* promoter were tethered to a glass surface by a single flagellum. These cells began to spin within several minutes after the addition of a *lac* inducer, and their rotational speed changed in a series of equally spaced steps. As many as 7 steps were seen in individual cells and, from the final speeds attained, as many as 16 steps could be inferred. These experiments show that each flagellar motor contains several independent force-generating units comprised, at least in part, of motB protein.**

Cells of a *motB* inducible strain were tethered to a coverslip, exposed to a *lac* inducer, and viewed with a microscope linked to a video recorder. The rotational behaviour of one such cell is analysed in Fig. 1. The cell remained in roughly one position for 16.3 min following the addition of inducer, executing brownian motion with a fixed mean orientation about its point of attachment. Then it suddenly began to spin, gaining speed over a period of ~17 min before levelling off at a constant speed. Abrupt changes in rotation rate were evident, particularly at the slowest speeds. Most cells in the population of 32 studied started to spin between 5 and 8 min from the time of induction; these latencies ranged from as little as 3 min to over 25 min. The time spent at the lowest speed was highly variable, ranging from a few seconds to a few minutes. The cell of Fig. 1 started spinning counterclockwise (as viewed with the cell body in front of the tethering surface, the direction corresponding to smooth swimming[4]), and, as the rotation rate increased, spun alternately clockwise (CW) and counterclockwise (CCW). The directional bias (the probability of spinning CCW) of the cell was unity at the lowest speed, but it fell to a lower value soon afterwards and remained relatively constant for the remainder of the experiment. The reversal rate was zero at the lowest speed, then increased dramatically during the next few minutes and levelled off long before the cell reached its maximum speed. The asymptotic values for directional bias and reversal rate were similar to those found for wild-type cells[5,6]. Cells rarely changed direction at the slowest speed: only two of the cells studied showed brief CW intervals at this level, but all reversed frequently at higher levels. At any given level, cells that reversed spun CW or CCW at the same speed.

Figures 2, 3 document stepwise changes in rotation rate for two more cells. A rapid doubling of rotation rate was characteristic of the first transition: for 15 cells in which this transition was clearly resolved, the mean speed ratio (±s.e.) was 2.05 ± 0.08. Note that the cell of Fig. 3 underwent transitions that either increased or decreased the speed by one level, spinning at four different levels over the interval shown. Evidently, the incorporation of functional force-generating units is not irreversible.

By arbitrarily assigning the initial rotation rate of a cell to level 1, the next higher rate to level 2, etc., a set of levels was derived for each cell. Figure 4 plots mean rotation rate against level number for four representative cells in which multiple levels were observed. As many as seven distinct levels (excluding

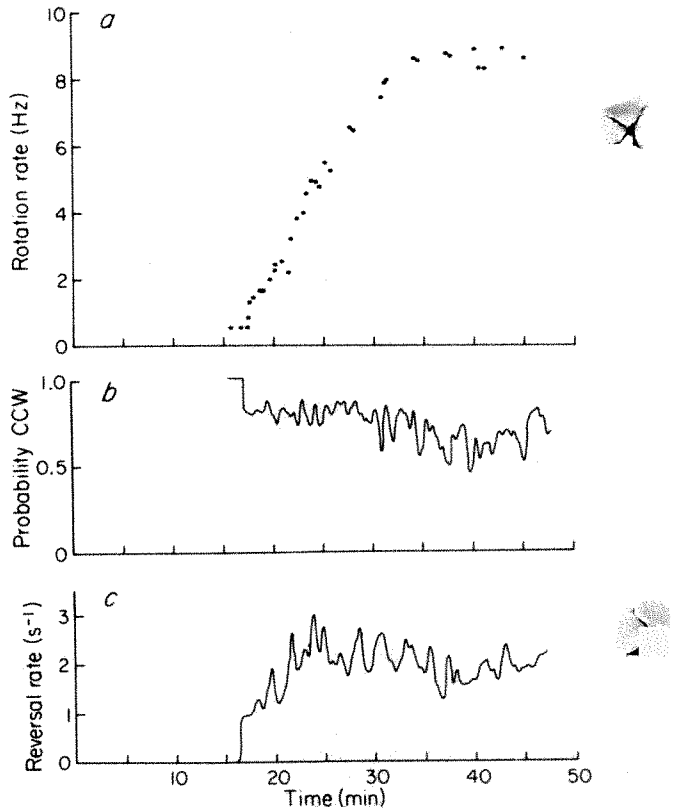

Fig. 1 Rotational behaviour of a single tethered cell, following initiation of transcription of the wild-type *motB* gene at time $t = 0$. *a*, Time course for induction of rotation; *b*, directional bias; *c*, reversal rate. The points in *a* show the average rotation rate computed from 30–300 revolutions registered by computer. Directional bias and reversal rate were determined as described previously[5,6]. The cell began to spin at $t = 16.3$ min at 0.53 ± 0.03 Hz (mean ± s.e.m. for 33 revolutions). It levelled off at $\sim t = 33$ min at 8.57 ± 0.07 Hz (mean ± s.e.m. for last nine data points).

Methods: Cells of strain HB154 (see below) were grown in minimal medium, washed and tethered in motility medium, as described previously[6], except that ampicillin (50 μg ml^{-1}) and tetracycline (10 μg ml^{-1}) were present in all media. At $t = 0$, the motility medium was replaced by a minimal medium containing glycerol and essential amino acids[19], as well as 1 mM isopropyl-β-D-thiogalactopyranoside (IPTG)[20]. In subsequent experiments, the cells were exposed to this medium (without IPTG) 10 min before the addition of the inducer; this appeared to increase the number of cells that responded without changing the kinetics of their induction. The flow cell was mounted on the temperature-controlled stage (32 °C) of an inverse phase-contrast microscope (Nikon Optiphot with a BM ×40 objective) linked to a video camera (Ikegami ITC-47; 2:1 interlace) and recorder (Panasonic NV-8950, VHS format). A digital time display (accurate to 1/60 s, a single video frame) was superposed on the video image[21]. The speed analysis of the videotaped records is described in Fig. 2 legend. Construction of *motB*-inducible strain HB154 began with plasmid pGM1, a pBR322 derivative carrying ampicillin resistance and a restriction fragment of the *mocha* operon[22] fused to *lac*Zp, originally produced to direct *motB* overproduction[18]. The fragment contained the C-terminus of the *motA* gene and a complete copy of the *motB* gene. A λgt1–pGM1 hybrid phage was made by cutting the plasmid and the phage at their unique *Eco*RI sites, ligating the mixture, and using the resultant constructs to infect *E. coli* strain RP3087 (an AW405 derivative[23] prepared by J. S. Parkinson carrying the *motB*^{580} allele[1] and deleted for λ-att) in the presence of ampicillin). An ampicillin-resistant transductant was selected which was lysogenic for λ; this cell presumably maintains the phage in a plasmid state using the pBR322 origin of replication. An F′ element carrying *lacI*^{Q} was then crossed into this strain to repress the *lac* promoter[24]. The hybrid phage copy number was reduced by adding a second plasmid, pMB9, bearing tetracycline resistance[25], and the transformed strain, designated HB154, was maintained under double antibiotic selection. This strain was immotile in the absence of a *lac* inducer; when tethered, less than 3% of cells showed any evidence of rotation.

level 0) were resolved using the video technique. For objects the size of bacteria, the angular rotation rate is strictly proportional to the applied torque; therefore, the linearity of these plots implies that the steps in torque associated with transitions between levels are equal. Evidently, each mot protein, or protein complex, contributes the same increment of torque to the flagellar motor, at least for the incorporation of up to seven force-generating units. Unfortunately, most cells in which multiple levels could be measured came off the glass or became stuck to it, prematurely terminating the experiment at speeds ranging from ~2 to 8 Hz.

The cell of Fig. 1 was an exception; the rotation rate of the first level was measured accurately, and the cell continued to spin until its speed reached a maximum value. In this case, the ratio of the final to the initial speed (16.2 ± 0.8) provides an estimate of the total number of force-generating units in the intact motor. If the efficiency of the flagellar motor remained constant over the range of speeds covered (as argued below) and all the force-generating units continued to operate independently, the motor in this cell contained about 16 such units. We also compared the mean rotation rate at level 1 for the population of cells studied here (0.76 ± 0.08 Hz; mean ± s.e.m. for 14 cells) with that of fully energized wild-type cells used in a previous study[7] (11.20 ± 0.46 Hz; mean ± s.e.m. for 33 cells). The ratio of these means (±s.e.) is 14.7 ± 1.7, again suggesting that each flagellar motor could contain up to 16 independent force-generating units. Sixteenfold rotational symmetry has been found for an M-ring of the *E. coli* flagellar motor[8]. This is also the number (usually 15, sometimes 14 or 16) of membrane particles ('studs') seen at the periphery of annular depressions in freeze-fracture electron micrographs of the cytoplasmic membrane at the flagellated poles of another bacterium, *Aquaspirillum serpens*[9].

The data of Fig. 4 do not indicate the existence of a rotational threshold: each curve extrapolates to the origin. It is possible

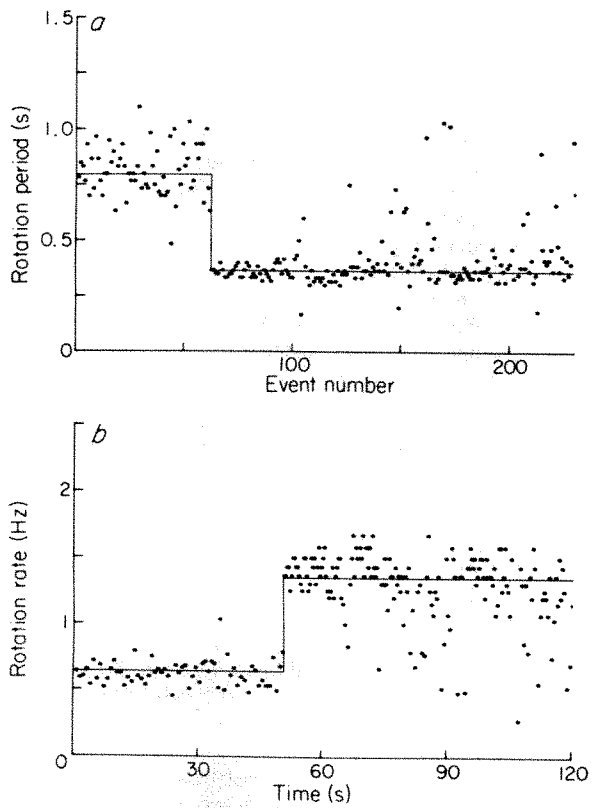

Fig. 2 Stepwise doubling in rotation rate of a tethered cell induced for motB synthesis. *a*, The first 280 rotation periods, plotted sequentially; *b*, rotation rate as a function of time computed from these periods. The solid lines represent the mean periods or rates for different intervals; see below. The cell started to spin 6.9 min after addition of inducer and doubled its rotation rate 52 s later, jumping from 1.28 ± 0.08 Hz (mean ± s.e.m. for 61 revolutions) to 2.67 ± 0.10 Hz (mean ± s.e.m. for 166 revolutions), a factor of 2.09 ± 0.15. The transition was completed in less than four video frames (67 ms), our limit of resolution.

Methods: The rotation periods were measured with a device linked to a computer (Apple II$^+$, containing a California Computer Systems 7440A Programmable Timer card connected to custom-built electronics) that generated a pulse whenever the image of a particular cell crossed a video cursor. The intervals between successive passages were stored in arrays for subsequent analysis. All of these data points are shown in the figure. The instantaneous rotation rate was computed from the reciprocal of each rotation period. Note that the points at large rates tend to fall on 'layer lines'—this reflects the fact that video images are recorded at 60 frames s^{-1}; the time intervals are constrained to be multiples of 16.7 ms. This limitation is significant when the rates are high. As the cells often changed direction, some intervals did not correspond to complete revolutions of the cell body. These intervals were shorter than adjacent intervals if the image changed direction within half a cycle after crossing the cursor; otherwise they were longer. Also, cells had a tendency to stick to the glass; when this happened, the measured period was abnormally long. An interactive graphics program allowed the operator to identify and eliminate most of these events from calculations of mean periods or rates. The standard error for each mean was obtained from the root mean square deviation from the mean of the edited distribution; this deviation was divided by the square root of the number of rotation periods and then adjusted upwards to compensate for the truncation due to editing (assuming that the parent distribution was gaussian).

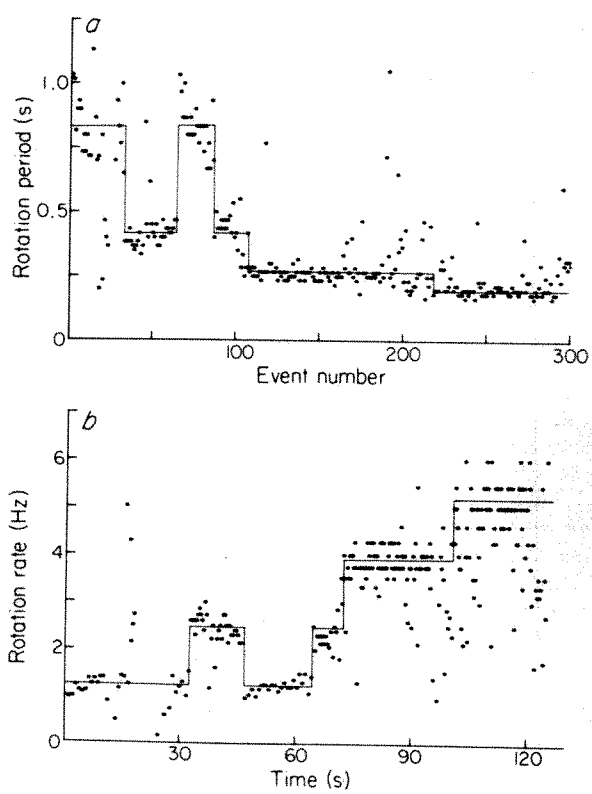

Fig. 3 Stepwise changes in rotation rate of another tethered cell induced for motB synthesis. *a*, The first 300 rotation periods, plotted sequentially; *b*, rotation rate as a function of time computed from these periods. The solid lines represent the mean periods or rates for different intervals, computed as described in Fig. 2 legend. The cell started to spin 5.9 min after the addition of inducer. Mean rotation periods tended to decrease in a harmonic series (as $1/n$, with n an integer); the corresponding rotation rates increased in an arithmetic series (as n). For large n, transitions between rotational periods of different mean amplitude became increasingly difficult to discern; as a result, the scatter in rotation rates became relatively more severe.

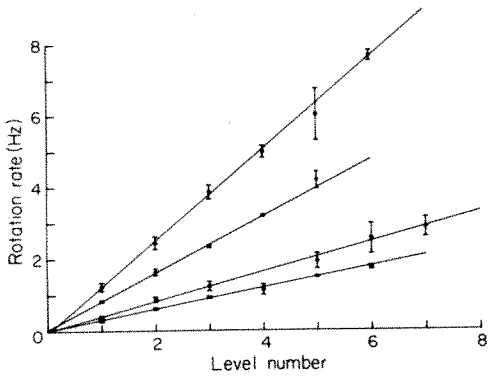

Fig. 4 Dependence of rotation rate on level number for four different cells. The vertical bars show the s.e.m., computed as described in Fig. 2 legend, and the solid lines are weighted least-squares linear fits, not constrained to pass through the origin. The different slopes reflect the variations in rotational drag from cell to cell (see text).

that the first transition that we have observed is not between levels 0 and 1, but rather between higher levels, say, 1 and 2. The possibility that a fully energized cell has no threshold is ruled out by the observation that the mean position of a paralysed cell (or flagellar filament[10]) remains fixed before the onset of rotation. It could be that the barrier to rotation in a fully energized cell is abolished by the introduction of functional mot protein. This question can be resolved by measuring speed as a function of protonmotive force in cells having different fixed numbers of force-generating units.

Given the increment in rotation rate from level to level, it is possible to infer the torque generated by a single force-generating unit. The constant of proportionality relating the torque generated by the motor to the rotation rate of the cell is the viscous drag coefficient, which depends only on the geometry of the cell, its position relative to the tethering surface, and the viscosity of the external medium[11]. Drag coefficients were estimated by assuming that cells behave as cylinders with hemispherical endcaps, rotating about an axis through the centre perpendicular to the long axis[12]. We neglected the interaction with the tethering surface, which is small[13], and the fact that cells are often tethered towards one end. The latter effect can increase the viscous drag by more than a factor of two[13], thus the drags calculated here represent an underestimate. The increments in torque from level to level for different cells appeared to be distributed normally with a mean (±s.d.) of $2.7 \pm 0.8 \times 10^{-12}$ dyn cm (11 cells). This value may be considered an approximate lower bound for the torque associated with a single force-generating unit; the torque is approximately the same for all units in all cells.

Given this result, it is possible to calculate the number of protons passing through a force-generating unit in one revolution. The energy balance for the motor can be written as $2\pi M = \varepsilon N e \Delta p$, where M is the torque, e is the electron charge, Δp the protonmotive force, N the total number of protons per revolution passing through the motor, and ε the motor efficiency, which could vary, for example, with angular velocity or protonmotive force. The left-hand term is the work done per revolution in driving the cell around. The right-hand term is the total work available from the proton gradient times the efficiency. Experimental evidence that the flagellar motor runs at constant torque at low speeds[14,15] implies, for these motors, that the product εN is constant. For any tightly coupled motor model, in which the passage of protons through the cell membrane is obligatorily coupled to rotary motion, N is constant. Given the experimental evidence for constant torque, this implies that ε is constant. Furthermore, if the motor in such a model is non-dissipative, that is, if it functions reversibly with no energy going into heat, then the efficiency will be unity.

A model of this kind has been proposed in which force is generated by the interaction of n proton channel complexes (independent force generators) situated around the periphery of a disk bearing m proton-binding sites[16]. The number of protons passing through a single channel complex in one revolution is m. Assuming unit efficiency, the torque generated by this channel complex can be written as $M = me\Delta p/2\pi$, where it is assumed that the efficiency is one. Given this torque and the protonmotive force, with $M \geq 2.7 \times 10^{-12}$ dyn cm and $\Delta p = 162$ mV (ref. 17), we estimate m to be ≈65. The total number of protons passing through a motor with n channel complexes in one revolution is $N = nm$. Assuming that the full complement of force generators is 16, N is of the order $16 \times 65 = 1{,}040$, in close agreement with an earlier estimate based on similar assumptions of tight coupling and zero dissipation[11].

The *motB* gene product is a peptide of molecular weight ~39,000 which is known to assemble in the cytoplasmic membrane without proteolytic cleavage; this mode of insertion has been confirmed in minicell preparations which are unable to synthesize any other flagellar proteins[18]. Here we have found that the rotation rate of tethered, paralysed cells increased in a stepwise fashion concomitant with motB synthesis. The simplest explanation for this result is that the wild-type motB peptides diffuse to the vicinity of the flagellar motor and act there, either alone or in conjunction with other components (for example, motA), as independent force-generating units. We cannot exclude the possibility, however, that the motB protein activates some other component that, in turn, incorporates as a force-generating unit. Since the rotation rate occasionally decreased in stepwise fashion, incorporation is reversible. The chromosome of the strain that we used carried a point mutation in *motB*; therefore, defective copies of motB protein might have been present before induction. In that event, the addition of functional force-generating units could have involved displacement rather than simple incorporation. As many as 16 force-generating units can be accommodated—it is attractive to suppose that these are transmembrane particles comprised of motA and motB protein[15,16].

We thank Chris Kaiser for the construction of strain HB154, which made this work possible; other strains were provided by Gail Mandel and Sandy Parkinson. We thank Felice Borisy for technical assistance; Markus Meister and Mel Simon for helpful discussions; and Shahid Khan, Jeff Segall, Pat Conley and Bob Smyth for their comments on the manuscript. This work was supported by US NSF grant PCM-8215126. S.M.B. acknowledges support of a Proctor and Gamble Fellowship and from the National Research Service Award Program of the NIH.

Get into fermentation at low cost

Here's a low-cost fermentor that satisfies nearly every critical need for the growth of suspension cultures. The MultiGen is a research tool for process development and other studies. Whether you're interested in anaerobes, aerobes, filamentous organisms or mammalian cells, the MultiGen can do it all: control temperature, agitation and aeration, pH and dissolved O_2. This fermentation package has everything you need—air and exhaust gas filter cartridges, sterile sampler, heat exchanger, air sparger, gas overlay port and a choice of agitator designs. The impeller is magnetically coupled to reduce contamination, yet provide the power needed for viscous fermentations. Send today for 84 page fermentation catalog

TWO NEW reliable, up-to-date and complete biotechnology information resources.

EXAMINE ON FREE APPROVAL WITHOUT COMMITMENT

Detailed information on every aspect of biotechnology worldwide

An indispensable guide to: ★ Products, services and research ★ Companies ★ Government and international agencies ★ Information sources

THE INTERNATIONAL BIOTECHNOLOGY DIRECTORY 1984 —

- is thoroughly international
- features a unique BUYER'S GUIDE to products, research and services
- covers both the old and new biotechnologies

The Directory tells you:

★ Who your competition is, and what they are doing.

★ Who are potential customers and suppliers.

★ Where to buy equipment, chemicals and services.

★ Where culture collections are located and what cultures they hold.

★ Who imports/exports biotechnology products in over 20 countries.

★ Which government departments are associated with biotechnology.

All compiled by the eminent biotechnologist Dr. Jim Coombs and now available to you on **FREE APPROVAL.**

Macmillan Hardcover 400pp
November 1983
ISBN 0 333 35140 1
£50.00/A$100.00

Information Sources in Biotechnology

★ covers both old and new technologies

★ covers technical and commercial literature

★ covers difficult and hard to trace sources

★ includes over 20 at-a-glance evaluation tables

★ provides an Index of publishers and their addresses

Dr. Crafts-Lighty, Head of Information and Library Services at Celtech Limited, systematically and critically reviews all the important information sources:

• books • conferences • trade periodicals • research periodicals • computer databases • patent • market surveys • directories • organisations • secondary sources

MAMMALIAN SEMIOCHEMISTRY
The Investigation of Chemical Signals Between Mammals

by **E.S. Albone,** *The Science School, Clifton College, Bristol*

This book provides the first unified, chemically-orientated introduction to mammalian semiochemistry, a developing subject area bordering on biology and chemistry. A great deal of work has been done in insect semiochemistry, but mammalian studies are in their infancy. Although biologists have been aware of their significance for some time, the synthesis with chemistry is only just beginning. The author provides an overview of the origin, nature and significance of those substances which carry information or otherwise mediate interactions between mammals, or between mammals and other organisms in the shared natural environment, and a synthesis of the component disciplines. Most of what is currently known about the chemistry of mammalian signals is covered and a number of avenues for further exploration are suggested. The particular difficulties inherent in the complexity of mammalian systems are emphasised and the appropriateness of the phenomena concept in this context is examined. 'Response guided' and 'chemical image' strategies are discussed.

EQUILIBRIA, NONEQUILIBRIA, AND NATURAL WATERS
Volumes 1 and 2

by **R.M. Pytkowicz,** *Oregon State University*

This book develops aquatic chemistry, geology, and hydrology from first principles, and applies them to the aquatic environment and complex solutions found in oceans, rivers, lakes, and laboratories. It examines processes in natural waters within the framework of thermodynamics and heterogeneous kinetics and presents serious research applications. It covers acids, new solid-solution equilibrium work, complexes, redox reactions, the geochemistry of trace metals, and gas-water interactions.

DETERMINATION OF ORGANIC REACTION MECHANISMS

by **B.K. Carpenter,** *Cornell University*

This practical handbook presents concise descriptions of the most commonly employed experimental techniques for studying reaction mechanisms in organic chemistry. For each technique, all necessary theoretical background is covered, and at least one example of its application — taken from the research literature — is described in detail.

HEAD-SPACE ANALYSIS AND RELATED METHODS IN GAS CHROMATOGRAPHY

by **B.V. Ioffe** and **A.G. Vitenberg,** *both of Leningrad University, Leningrad, USSR*

This book describes new methods of head space analysis for the first time plus related methods based on the equilibrium between the liquid and gas states. It treats the new and rapidly developing independent field in gas chromatographic analysis based on the use of "out of column" phase equilibria and partition coefficients in gas-liquid systems. It describes the analytical and physico-Chemical applications of this new method. New principles of investigation chemical equilibria solutions are considered.

THE HIGH NITROGEN COMPOUNDS

by **F.R. Benson,** Retired, *ICI Americas Inc., Wilmington, Delaware*

What is the nature of chemicals with backbones of nitrogen? What structural possibilities have been realized? What physical, chemical, biological, and use properties result from linking nitrogen atoms in chains bearing organic and inorganic appendages?
This book, with a focus on nitrogen chains, has been written to try to provide at least partial answers to these questions. The conceptual parents of compounds with sequential nitrogen atoms were called hydronitrogens by the late Professor L.F. Audrieth in analogy to the hydrocarbons. It may be said at once that the derivatives of hydronitrogens exhibit distinctive chemical and physical properties and have diverse uses.

OPEN TUBULAR COLUMN GAS CHROMATOGRAPHY
Theory and Practice

by **M.L. Lee,** *Brigham Young University;* **F.J. Yank,** *Varian Instruments, Walnut Creek, California;* and **K.D. Bartle,** *University of Leeds*

This book presents a state-of-the-art treatment of gas chromatography, one of the most widely applied methods in analytical chemistry. It provides an integrated and in-depth compilation of the modern practice of open tubular gas chromatography. In addition, a comprehensive summary of the theory of this powerful technique as well as the relationship between this theory and its applications are analyzed.

Inflationary cosmology

Gary Steigman

The Very Early Universe.
Edited by G.W. Gibbons, S.W. Hawking and S.T.C. Siklos.
Cambridge University Press: 1983. Pp.480. £25, $49.50.

THE "standard" hot big bang model provides a good framework for understanding the early evolution and present structure of the Universe. The Robertson–Walker–Friedman (RWF) models are isotropic, homogeneous solutions to Einstein's gravitational equations in the presence of matter (nucleons) and radiation (microwave photons). Penzias and Wilson's discovery of the cosmic background radiation provided dramatic confirmation that these simple models could describe the early history of the Universe, and ushered in the "modern" era in the study of cosmology. The blackbody spectrum of the microwave background is established by electromagnetic interactions during the early evolution of the Universe and preserved during its later evolution by the homogeneity and isotropy of the RWF models. Furthermore, nuclear and weak interactions occurring during the first few minutes in the evolution of the Universe lead to the synthesis of the light elements, the abundances of which are observed to be in excellent agreement with the predictions of primordial nucleosynthesis in the standard (RWF) model. As for the more recent evolution, small deviations from the perfect homogeneity of the RWF models grow with time and may account for the observed large-scale structure of the Universe (galaxies, clusters, voids and so on).

The simplest hot big bang model has proved to be remarkably efficacious; to ignore its successes would be churlish. Nonetheless there are problems. Many questions and puzzles are neither answered nor addressed within the context of the standard model. For example, the "Planck time" $t_p \approx (G\hbar/c^3)^{1/2} \approx 10^{-43}$s is a "natural" timescale for cosmology. The present Universe is very old ($t_0 \approx 10^{10}$ yr $\approx 10^{60} t_p$) and yet very young in the sense that the spatial curvature is not yet dominant; our Universe is very "flat". The response of the standard model to the age–flatness puzzle is to appeal to initial conditions: the Universe is the way it is because it was the way it was.

A different problem is posed by the matter content of the Universe. The observed Universe consists overwhelmingly of matter; antimatter is absent. Why? Early on there must have been a tiny excess of matter over antimatter so, when nucleon–antinucleon annihilation ceased, a trace amount of relic nucleons survived. The present ratio of nucleons to photons (η) is a measure of the requisite excess: $10^{-10} \lesssim \eta \lesssim 10^{-9}$. Within the standard model there is no explanation for the magnitude of η (or even why it should not be zero); η is the size it is because it was the size it was.

Even the observed large-scale homogeneity, a key ingredient of the standard model, is a serious puzzle. The finite speed of light guarantees the existence of particle horizons so that the various parts of the Universe from which the microwave radiation originates were never in causal contact. Why, then, is the flux observed to be so very uniform? Why, indeed, is the large-scale Universe so very homogeneous?

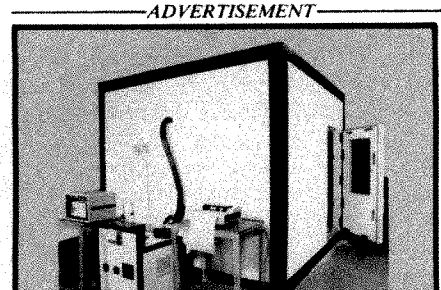
There are still further questions. Why is the cosmological constant so small? Is it zero? What of the singularity of the RWF models? The list goes on, but all is not darkness and despair. Less than a decade ago the tide of a revolution in cosmology began to swell. Today it has risen to a flood. Its source was high-energy physics. The successful unification of the electromagnetic and weak interactions led to the predictions of new phenomena such as neutral current interactions; the gauge theory of the strong interaction predicted especially simple behaviour at high energy (asymptotic freedom); Grand- and Super-Unified theories were proposed predicting new phenomena and new particles, often at energies far beyond or rates far below those attainable in the laboratory. Some cosmologists and a few particle physicists quickly appreciated that the early Universe was the ultimate accelerator — the particle physics laboratory of last resort. That particle physics might provide the key to solving various cosmological puzzles in the early evolution of the Universe was much less obvious. Yet the relationship between particle physics and cosmology which has blossomed in recent years, while not entirely trouble free, has been a remarkably fecund affair.

For example, a solution to the asymmetry puzzle is provided by Grand Unified Theories (GUTs) in the context of the very early evolution of the Universe. In most GUTs, baryon number is not conserved and charge (C) and charge-parity (CP) conservation are violated. As Sakharov noted in his recipe for generating a baryon asymmetry, these are two of the three required ingredients. The third, deviation from equilibrium, is provided by the expansion of the Universe. Although there are too many free parameters in the GUTs to permit a calculation of the nucleon to photon ratio, η, from first principles, it is nonetheless clear that a framework for this calculation now exists. No longer need we appeal to initial conditions: η is what it is because of baryon number and C and CP violating interactions which occurred during the very early evolution of the Universe. The universal baryon asymmetry and the instability of the proton are two sides of the same coin.

Lest we be lulled into a false sense of security, it must be said that the same GUTs which solve the asymmetry puzzle, predict the existence of superheavy ($\sim 10^{16}$ GeV) magnetic monopoles. In the standard model these monopoles are produced during the same epochs in which the baryon asymmetry is generated and they survive in abundances comparable to that of the nucleons. The enormous mass density in the relic monopoles would have driven the Universe to expand so rapidly that today, when the blackbody radiation is at a temperature of 3K, the Universe would be only $\sim 10^3$ yr old! (It is often stated, incorrectly, that relic monopoles "close" the Universe. The curvature neither knows nor cares about the stuff of the Universe.) So, GUTs and cosmology solve the baryon asymmetry puzzle but present us with a new problem — relic monopoles; failure snatched from the jaws of success!

With the monopole problem as one of its catalysts, there then occurred a revolution within the revolution. The cosmological constant emerged from the closet to play a significant role during the very early evolution of the Universe. As Zeldovich and others have noted, the cosmological constant (Λ) may be regarded as the energy density of the vacuum ($\Lambda \equiv 8\pi G\varrho_v$). Although Λ is small today ($\Lambda < H_0^2$, $\varrho_v < 10^{-4}$eV cm^{-3}), the energy density of the vacuum would have been enormous during the very early evolution of the Universe ($\varrho_v \sim 10^{110}$–10^{126} eV cm^{-3}). K. Sato and A. Guth realized that the vacuum energy density would drive the early evolution of the Universe and Guth appreciated that the "inflationary" exponential expansion would, in one fell swoop, solve a myriad of cosmological conundrums. Cosmology hasn't been the same since.

In the summer of 1982, Stephen Hawking, with the support of the Nuffield Foundation, organized what turned out to be a very productive workshop in Cambridge, UK, on "The Very Early Universe". Truly international in character — the participants came from Great Britain, continental Europe, the United States and the Soviet Union — the meeting covered topics as diverse as quantum gravity and galaxy formation, monopoles, strings and massive neutrinos, photinos and axions, supersymmetry, GUTs and the cosmological constant. Not surprisingly, the "new" inflationary models of Linde and of Albrecht and Steinhardt were the centre of interest. And rightly so, for, if it could be implemented, new inflation would solve the age, flatness,



homogeneity and monopole problems. Furthermore, the reheating after the inflationary epoch would then account for the enormous entropy ($\gtrsim 10^{87}$ photons in the observable Universe) as well as the large entropy per baryon ($\eta^{-1} \gtrsim 10^{9}$ photons per nucleon) of the Universe. What is more, new inflation predicts perturbations of the spectral form first suggested by Harrison (and, therefore, now known as the Zeldovich spectrum!). The workshop was particularly noteworthy in that the participants arrived emboldened by recent successes and left with further successes and new problems with which to wrestle. The struggle still continues.

This book, a record of the workshop, provides a window on the excitement of the meeting itself. Virtually all the articles are interesting, comprehensive and well written. Several are, and will remain, valuable reviews of an entire subfield of cosmology or particle physics. Although some are highly technical, most can be tackled by the knowledgeable graduate student; cosmologists will find the particle physics articles comprehensible and vice versa. Especially worth reading are the introductory and summary reviews by Wilczek; the cosmology article (virtually a monograph on modern cosmology) by Rees; the primer on GUTs and Supersymmetry by Ellis; the self-contained introduction to and review of monopoles by Preskill; the inflationary articles by Guth, Linde, Steinhardt and Hawking; and the outlines of the development of perturbations in the inflationary models by Turner, and by Lukash and Novikov. I have learned a great deal from these articles and expect to return to them frequently in my teaching and research. Conspicuous by its absence, however, is a contribution by Starobinsky who, to judge from the comments of many of the participants, played a major role in discussions at the meeting.

Stephen Hawking is owed a debt of gratitude for having attracted the right people to the right workshop at the right time. In *The Very Early Universe* Hawking and his co-editors, G.W. Gibbons and S.T.C. Siklos, have provided the astro–particle physics community with a valuable work of reference. □

Gary Steigman is Professor of Physics in the Bartol Research Foundation of the Franklin Institute, Newark, Delaware, and Adjunct Professor in the Physics Departments at the University of Delaware and the University of Pennsylvania.

Accounts of energy

Colin Sweet

The Economics of Nuclear Energy.
Edited by L.G. Brookes and H. Motamen.
Chapman & Hall/Methuen: 1984.
Pp.420. £27.50, $65.

ATTITUDES towards nuclear power in one country have always been more influenced by developments elsewhere than is the case with any other industry, with the possible exception of the defence industries. It is appropriate, therefore, that this new addition to the literature should set out to be international in scope. The 23 authors are drawn from six countries.

Despite its title, the book is not in any sense an economics text. Nor is it a straightforward exercise in applied economics. Rather, it is series of essays on different aspects of nuclear power as seen from different countries. This approach certainly has its merits, but to contribute something more to the current debate the book would have had to have been explicitly eclectic. As it is, while the authors have different ways of making their economic assessment (such that one cannot often be compared with another), the conclusion that they all arrive at, with one possibly neutral exception, is that nuclear power is the most attractive option on offer for future growth in electricity generation.

The first three chapters of the book are concerned with a systems analysis of electricity supply and are in many ways the most satisfactory. They provide a good basis for discussion of economic pricing. One point which emerges very clearly is the great complexity of the nuclear–electric system, from the mining of uranium to the delivery of the product to the consumer. And between them, these chapters — by C. Starr and O. Yu (United States), L. Gouni (France) and T. Berrie (UK) — bring out well the technical constraints of electricity systems generally. Especially for the layman this is good start. However the treatment is not without problems which, once raised, recur in the so-called economic discussions of the subject. Starr and Yu conclude that centralization of production is a logistical objective. Gouni follows by drawing attention to the monopolistic tendency that accompanies such centralization. But like his counterpart in the UK, J. Rhys (Electricity Council), Gouni does not really face the contradiction between this reality and the assumptions of a competitive market. The result is that Rhys's chapter in particular, which is one of the few that tackles the problem of economic pricing, has an overly academic air. His conclusion that "In the long run, provided nuclear power can be established as the cheapest means, it is likely to be the dominant factor in determining the overall level of electricity prices" may be conceptually a narrow basis for making a judgement but it is about the most open-ended statement to be found in the book.

One reason why the book is methodologically weak is that it rests too much on the thinking that prevailed when nuclear economics was inseparable from propaganda of the institutionalized kind. It is not the authors' fault that their book went to press before they had time to absorb the massive amount of information put before the Sizewell "B" Public Inquiry. Nevertheless it is unfortunate. In their submissions, the Central Electricity Generating Board appear finally to have put historic cost accounting behind them for purposes of investment appraisal and to have embraced opportunity cost analytical studies. This is something which British authors have to communicate to their opposite numbers in nuclear establishments in other parts of the world. It is a pity that here the opportunity was missed.

Interestingly enough, the best comparative study of nuclear and coal-fired generation comes from D. Schmitt and H. Jung of Cologne University. They use the requirement revenue method which computes likely discounted costs of future projects against future revenues. The cost assumptions are not always convincing and the treatment of the demand side is conspicious by its absence (on this point they could do well to read what Gouni has to say about the demand factor). They are however aware of the limitations of such economic exercises and indeed they make the observation which one would like to have seen feature more prominently in other contributions — that the future of nuclear power will not be decided by economics. "The crucial barrier is public

ACADEMIC PRESS

STATISTICAL ANALYSIS OF SPATIAL POINT PATTERNS

Peter J. Diggle

January 1984, 164pp., 0.12.215850.4
$25.00/£14.95 (UK only)

A spatial point pattern is a set of points, irregularly distributed in an essentially planar region – for example, trees in a forest or cell nuclei in a microscopic tissue section. This book presents an up-to-date account of models and methods used in the statistical analysis of spatial point patterns and their application to biological data.
Both univariate and multivariate patterns are covered and numerous illustrative examples are provided using real biological data sets which are given in full as an appendix. The graphical presentation of results is emphasized and the book includes over eighty diagrams.

CEPHALOPOD LIFE CYCLES

Volume I: Species Accounts
Volume II: Comparative Reviews

Edited by Peter Boyle

Volume I: January 1984, 516pp., 0.12.123001.5
$120.00/£70.00 (UK only)
Volume II: in preparation

Recent evidence suggests that cephalopods are of major quantitative importance to the marine ecosystem and that they have a role to play in many marine food chains. These volumes present the only cohesive study of the subject in the English language, bringing together much unpublished data as well as published material from very diverse sources.

EUROPEAN MIRES

Edited by Peter Moore

May 1984, 367pp., 0.12.505580.3
$75.00/£49.00 (UK only)

The unique hydrological features and floristic variety of peatlands combine to fascinate many botanists and ecologists. This book brings together, in English, the fruits of many studies previously only published in Scandinavian and Central European languages, providing a broad summary for the English speaking researcher. The book's approach is mainly phyto-sociological, comparing and contrasting the various mire types and their classification in the different countries of Europe.

BIOLOGY OF THE EUCESTODA

Volumes 1 and 2

Edited by C. Arme and P.W. Pappas

Volume 1: December 1983, 320pp., 0.12.062101.9
$55.00/£34.00 (UK only)
Volume 2: December 1983, 360pp., 0.12.062102.9
$58.00/£38.00 (UK only)

This two-volume work is the first major treatment of a subject that has hitherto received inadequate attention in parasitological literature – the *Biology of the Eucestoda*. Covering a wide range of topics, and with contributions from leading experts in the field, these two books comprise the most authoritative and comprehensive study of tapeworm biology to date. It contains review articles on eucestode evolution and systematics, on ecology and on morphology, fine structure and development. Other contributions are concerned with biochemistry and physiology, pathology, immunity, and chemotherapy. Both volumes contain extensive illustrations, tables and references.

BEYOND NEO-DARWINISM

An Introduction to the New Evolutionary Paradigm

Edited by Mae-Wan Ho and Peter T. Saunders

February 1984, 384pp., 0.12.350080.X
$40.00/£25.00 (UK only)

The Neo-Darwinism synthesis has been subject to widespread criticism in recent years. This volume is concerned with the next step: the development of an alternative. It brings together work from a variety of disciplines, demonstrating the breadth of vision of the new paradigm and the common threads which hold it together.

HORSE MANAGEMENT

Edited by John Hickman

April 1984, 339pp., illustrations, 0.12.347220.2
$32.00/£20.00 (UK only)

The editor, Colonel Hickman, presents here a complete account of horse care based on his own considerable experience in this area. With each chapter written by a recognized expert, *Horse Management* covers all aspects from birth through to training, including equine reproduction, housing the horse, foods and feeding, stable management, the foot and shoeing, exercise and training

European Biophysics Journal

EBJ

ISSN 0340-1057 Title No. 249

Continuation of *Biophysics of Structure and Mechanism*

Editorial Board
P. M. Bayley, Managing Editor, National Institute for Medical Research, London; **H. J. C. Berendsen,** University of Groningen; **F. Conti,** Institute of Cybernetics and Biophysics, Camogli; **R. Rigler,** Karolinska Institute, Stockholm; **E. Sackmann,** Technical University, Munich

The **European Biophysics Journal** presents the latest research findings in a wide range of areas employing the principles of physical science to understand biological structure and function. Produced in a larger format that its predecessor, the **European Biophysics Journal** is edited by a board of respected scientists with expertise in the rapidly developing areas of the field. The journal publishes original research articles, reviews, and short communications which use a distinctively biophysical approach to all levels of biological organization. Specific topics of interest are:

- **molecular structure and interactions**
- **membrane and receptor biophysics**
- **thermodynamics and energetics of biological processes**
- **theoretical biophysics**

The **European Biophysics Journal** meets the same high production standards that have made Springer-Verlag publications synonymous with quality all over the world. Researchers in all areas of biophysics need to have constant access to the journal to stay-up-to-date on both experimental and theoretical developments. You can guarantee that access by subscribing.

Subscription Information:

Human Nature and Biocultural Evolution

Joseph Lopreato

In this major new text Professor Lopreato outlines a theory of human nature viewed as an interrelated set of genetically programmed behavioural predispositions, and a theory of biocultural evolution. His approach is based on a rich analysis of ethnographic, psychological and sociological arguments and data, as well as facts and theories from comparative zoology.

'admirably lucid and runs smoothly from sociology to biology and back again, showing it can be done. Professor Lopreato's grasp of evolutionary biology is truly remarkable. This book has a potentially unifying role to play.'

Women Scientists

The Road to Liberation

Edited by **Derek Richter**
Institute of Neurology, University of London

April 1982 £10.00 313pp ISBN 0 333 32468 4

Anyone should find these glimpses of lives in other cultures intriguing."

"Enlightening for any aspiring scientist who thinks a scientific career is a logical progression from research post to lectureship to chair." **Georgina Ferry, New Scientist**

This book draws together the personal and intellectual biographies of eleven women biomedical scientists. The individual stories are informative, fascinating, and sometimes moving, and cover cultures as diverse as those of India, Iran, USA and the USSR.

acceptance" as far as Schmitt and Jung are concerned, and that means that "The expansion of nuclear energy thus becomes a problem of political decision making". They are surely right.

The least satisfactory chapters in the book are one from the United States and two others from France. The American study, by G.R. Corey, is the familiar full cost analysis which abounds in the past literature. It is replete with data that can hardly be checked and assumptions that are heroic at nearly all points. The contributions from the French Atomic Energy Authority (CEA) are the worst kind of institutional arrogance. This is a great pity, but not a surprise: the French commitment to nuclear power is not only greater than that of any other country, but their programme is beset with considerable problems of overcapacity and cost. J. Baumier and L. Duchatelle, and their colleague L. Thiriet (appropriately from the public relations department), have no wish to explore problems. Baumier and Duchatelle write about the French Fast Breeder Reactor, Super-Phénix, which from an engineering point of view may prove to be an achievement. But from the economic standpoint it is a disaster. The attempt by the authors to juggle with figures in order to show that while the first station will produce power at twice the cost of a Pressurized Water Reactor the "cost ratios will progressively approach unity" is unconvincing and ought not be taken seriously (as I am sure it is not by Electricité de France).

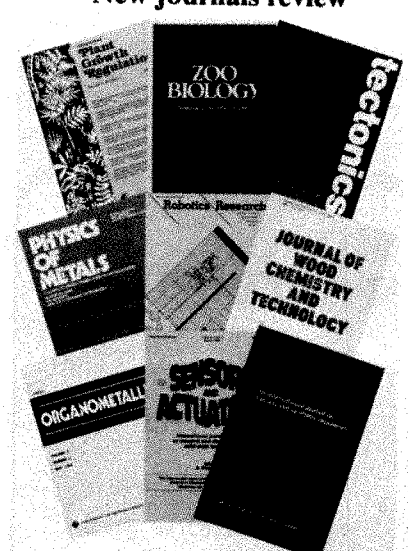
Less strident but characterized by the same cover-up technique is the contribution by A. Farmer of the United Kingdom Atomic Energy Authority. The recent stinging report by the Comptroller and Auditor General on the vast sum of money that has been expended on the UK Prototype Fast Reactor at Dounreay, which nine years after completion hardly works at all, ought to raise some very real questions about project evaluation and financial monitoring of nuclear projects. A British Fast Reactor of commercial size now appears to have been abandoned but the annual research and development allocations of £100 million plus continue. For how long? With what benefits? And for whom?

As an exposition of the manner in which nuclear power has developed its own peculiar brand of economics, which must be seen of course as a part only of its rationale, this book is informative and illuminating. Yet all books on nuclear power, without exception, ought to be read critically and with a certain degree of disbelief. Because this one does not carry a health warning, it needs to be consumed with at least as much care as its predecessors. □

Colin Sweet is Director of the Centre for Energy Studies at the Polytechnic of the South Bank, London.

The information man

Walter Gratzer



Essays of an Information Scientist, Volume 5.
By Eugene Garfield.
ISI Press, 3501 Market St, Philadelphia: 1983. Pp.848. $25 (North America), $28 (elsewhere).

"Ah, Mr Gibbon", the Duke of Gloucester is supposed to have observed, on being presented with the second volume of *The Decline and Fall of the Roman Empire*, "another damned, fat, square book. Always scribble, scribble, scribble, eh?". Likewise Eugene Garfield, whose business is the printed or processed word, and whose own output with this, his fifth volume of essays, culled from *Current Contents* and running to 848 pages, has probably by now exceeded Gibbon's life's work in the majesty of its bulk. It is true that, as he explains, in the essay entitled "How do you do it? Write all those essays, I mean", Dr Garfield has the advantage of Gibbon in that he marshals a staff of helpers who man his organization (the Institute for Scientific Information) and have titles such as Director of Communication, Manager of Bibliographic Research and Manager of Editorial Materials, not to mention two secretaries, called Sharon and Mary, their pens ever poised for dictation. All the same Dr Garfield's achievement is considerable, for he maintains a high level of readability, and from the well of statistics about science that he has sunk there gushes an inexhaustible stream of curious, interesting and sometimes outlandish information.

Dr Garfield has done more than invent *Current Contents* and the *Science Citation Index* to smooth the path of scientists: he has used the new information technology to generate a whole new human activity, which will undoubtedly become known (if it is not already) as *scientometry* or *scientometrics*. Although it had probably occurred to no one before Garfield had his first brainwave that anything of much consequence could be inferred from the references appended to every scientific publication, their function has undoubtedly undergone a surreptitious transformation. From being merely part of the *apparatus criticus*, designed to assist the reader to acquaint himself most easily with the background of the subject, references have acquired, with the emergence of "peer-review" and centralized funding, a ritual significance. They are now selected mainly to flatter, mollify or disarm. Why else, if not with a shifty eye to the impression that their bibliography might make on present or future members of a Study Section, do authors, as one of Dr Garfield's analyses has shown, cite by preference the work of their own compatriots at the expense of that from other countries? Conversely, scientists with undernourished egos are, as every editor knows, apt to make their dissatisfaction known if they believe their work to have received insufficient acknowledgement. As for autoreferencing (I cite Dorothy Parker), the advantage of self-praise is that it can be laid on thick and when it is most needed. Now that *Science Citation Index* ratings have even found a place in litigation, over such diverse matters as tenure or promotion and alleged maltreatment of laboratory animals, we disregard them, it seems, at our peril.

Like mercy then, citation is twice blessed (or three times if one takes account of ISI and Dr Garfield); it blesseth him that gives and him that takes. Moreover, Dr Garfield leaves us in no doubt that his league tables reflect merit in some sort. He rebuts the commonly heard argument that the best way to join that blessed host of the most cited authors — in Dr Garfield's terminology the *Nobel Class*, no less — one need only make some trifling improvement in an analytical colour reaction or devise a new buffer system for gel electrophoresis, by demonstrating that only a minority of the *Nobel Class* would be supplanted if their

New journals review

On 27 September *Nature* will publish the fourth annual review supplement devoted to science journals.

Criteria for inclusion of a journal in the 1984 issue are that:

(i) the first number appeared, or the journal was retitled, *between June 1982 and May 1983* (the second cut-off date allows at least three issues of a journal to have been published, the minimum number on which a reasonable judgement can be based);

(ii) it is published at least three times a year;

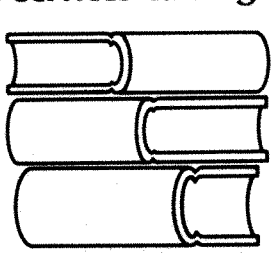
(iii) the main language used is English.

Publishers and learned societies are invited to send *four different issues of each suitable periodical, including the first and most recent numbers* (if from outside the United Kingdom, by air mail) to: The Review Editor, *Nature*, 4 Little Essex Street, London WC2R 3LF, England. Subscription details, if possible for both 1984 and 1985, should be included.

single most cited paper were taken away. And yet, and yet . . . looking down the register of the *Nobel Class*, we see amongst the Nobel laureates and aspirants the names (I would have thought by common consent) of some of the choicest noodles in all of science, as well as some striking absences (not a Huxley in sight for example); presumably some of these operate in sparsely populated fields, or then again perhaps, as Chargaff has suggested, it is less important to be first than to be last. Garfield himself quotes a testy letter from an illustrious virologist, to the effect that his *Citation Classic* (another of Garfield's coinages) is one of his less significant accomplishments, being cited exclusively for the procedure that it contains for washing and suspending bentonite clay, which is used as a nuclease inhibitor.

All the same, whatever one's (wholly subjective) reservations, Dr Garfield's statistics afford a unique panorama of science in action, and many a diverting insight into the intimate habits of its practitioners. The refinements of authorship are particularly rewarding. We learn for example that with success comes a modicum of generosity: Nobel laureates, once the bacon is safely home, tend to yield priority to their co-workers in the listing of authors. An examination of papers published in the *Journal of Physiology*, which as a matter of editorial policy places authors' names in alphabetical order, reveals that Professors with names such as Zweig, or those who have graduate students called Aardvark, take their business elsewhere. Indeed the citation-watchers, such as Professor Derek de Solla Price, have, it appears, been much exercised about how to apportion credit for authorship: should the first author be entitled to store up more riches in heaven than the second or the twenty-second? Should one receive equal benison for a share in a thirty-author bone-crusher of the kind common in particle physics, as for a solo effort? The experts, you will be relieved to hear, are working on it.

The scope of Dr Garfield's writings transcends the work of ISI, however. When Charles Dickens received as a contribution to the literary magazine, of which he was editor, a set of poems with the title "Orient pearls at random strung" he sent it back with the scribbled comment, "too much string". There is, to be sure, a certain amount of string in Dr Garfield's latest anthology, but overall he gives excellent value. His organization has endowed prizes and sponsored local artists; he writes pleasantly about these enthusiasms, and his dissertations on such subjects as risk assessment, and most of all on medical matters, are at times quite transfixing. His book is worth the money just for his accounts of those three arguments against the existence of God, acne, halitosis and venereal trichonomiasis. One looks forward to more in the same vein anon. □



Walter Gratzer is in the Medical Research Council Cell Biophysics Unit, King's College, London.

Metals on the brain

Laszlo Magos

Neurobiology of the Trace Elements (in two volumes).
Edited by Ivor E. Dreosti and Richard M. Smith.
Humana: 1983. Vol.1 pp. 374, Vol.2 pp.320. Each volume $49.50 (US), $59.50 (elsewhere).

THE title of this work refers to trace elements, but it is not without significance that only one chapter in the two books deals with an element which is not metal or metalloid. The first volume is dedicated to *Trace Element Neurobiology and Deficiencies*, the second to *Neurotoxicology and Neuropharmacology*; neuropharmacology, however, is represented by a single contribution only.

Though there are many common targets for essential and toxic metals — for example catecholamine metabolism for copper and manganese, or hippocampus for zinc, lead and trimethyltin — market research probably indicated that interest in one volume would frequently exclude interest in the other. As evidence of this, both volumes have the same foreword, preface and conclusions. As a toxicologist I cannot agree with the assumption — I found the first volume more cohesive, comprehensive and altogether better reading. One has the impression that the editors, with experience in trace metal deficiencies, were better equipped to conduct the authors of the first volume to play in concert but did not influence the authors of the second to the same extent. Moreover the correction of inconsistencies in the chapter on manganese in Vol.2 (for example when absorption is described) would have greatly improved this contribution.

In the first volume there are two chapters on copper, three on zinc and single chapters covering iodine, iron, selenium and cobalamine. There is very little repetition when more than one chapter is dedicated to the same metal. The authors balance well biochemistry, pathology, clinical and experimental investigations, and amalgamate diverse knowledge effortlessly, putting the main emphasis on developmental neurobiology.

The second volume has an excellent chapter on mercury, but this account is rather narrow in scope being restricted to the effects of methylmercury on the fetal brain. The hiatus is filled by a contribution on the behavioural toxicology of heavy metals, which, in addition to covering behavioural effects, concisely describes the neurotoxicity of methylmercury, metallic mercury and lead, and at least mentions arsenic and organotins. Given the effect of trimethyltin on the hippocampus, however, a chapter on these compounds should have been included. The rest of Vol.2 contains two chapters on cadmium and three on lead, with manganese, aluminium and lithium each being represented by single chapters. Though the teratogenecity of zinc deficiency is described in the first volume in detail, and the protective effect of zinc against the teratogenecity of cadmium in the second volume, it is not mentioned that cadmium inhibites the placental transport of zinc. Nevertheless the defects of the second book are relatively minor and it mainly suffers from comparison with Vol. 1.

Researchers in fields related to the neurobiology or neurotoxicology of trace metals will probably find, as I did, the reading of this not unusually expensive work to be rewarding. Beyond the information supplied, the quality of paper is excellent, the typography is clear and pleasant, and references, complete with titles, are plentiful and are arranged in alphabetical order at the end of the chapters. Both volumes are supplied with good indexes. □

Laszlo Magos is in the Medical Research Council Toxicology Unit, Carshalton, Surrey.

NEW PUBLICATIONS IN BIOCHEMISTRY

Lipases

edited by **B. BORGSTROM** *and* **H. L. BROCKMAN**

This work is written by specialists in their respective fields, guaranteeing a high quality of the book. The first part of the book deals with the general features of lipolysis discussing the background of lipolysis, the reaction schemes, the interfacial character of the process, its physicochemical nature and different experimental approaches. In the second part of the book emphasis is placed on mammalian enzymes and they are described in the order they are confronted with the original substrate – dietary fat – in the gastrointestinal tract. There follows lipoprotein lipase which converts the chylomicrons to remnants which are taken up by the liver as substrates for liver lipase. The hormone-sensitive lipase of the adipocytes and its regulation is dealt with in detail as are the lysosomal lipases. Also included are the lipoprotein lipase and bile salt-stimulated lipase of milk.

Enzyme Regulation by Reversible Phosphorylation — Further Advances

edited by **P. Cohen**

MOLECULAR ASPECTS OF CELLULAR REGULATION, volume 3

general editor: **P. Cohen**

Molecular Aspects of Cellular Regulation is an occasional series of books on multidisciplinary topics which are designed to illustrate general principles of cellular regulation.
This third volume is a follow-up to Volume 1 and provides authoritative accounts of a number of systems in which the importance of this phenomenon has come to be recognised over the past few years. Each article is written by leading workers in the field and because of the multidisciplinary nature of this subject is preceded by a long introduction to enable the general reader to understand the background to the topic under discussion.

Separation Methods

edited by **Z. DEYL**

NEW COMPREHENSIVE BIOCHEMISTRY, Volume 8

general editors: **A. NEUBERGER** *and* **L. L. M. VAN DEENEN**

This volume presents an overview of current chromatographic and electromigration separation methods with the emphasis placed on diverse biochemical applications with the necessary background in theory and instrumentation.
The aim of the book is to offer a fast and updated picture of current possibilities that chromatography and electromigration techniques offer to a biochemist.

1984 534 pages
Price: US $ 75.00 / Dfl. 195.00
ISBN 0-444-80527-3

Lysosomes in Biology and Pathology

VOLUME 7

edited by **J. T. DINGLE, R. T. DEAN** *and* **W. SLY**

This volume, the seventh in the well-established series 'Lysosomes in Biology and Pathology' covers the major advances which have recently been made concerning the biosynthesis and intracellular transport of lysosomal enzymes.
Written by major contributors in the field, the book discusses the understanding of receptor-ligand interaction, endocytosis, recycling of receptors and membranes, and entry of endocytosed viruses and toxins into the cytosol.

1984 512 pages
Price: US $ 125.00 / Dfl. 325.00

Chloride Transport Coupling in Biological Membranes and Epithelia

edited by **G. A. GERENCSER**

These original, contemporary review papers by outstanding international researchers describe the mechanisms, and regulation of the mechanisms, by which chloride is transported across biological membranes. The contributors study the major membrane systems involved in chloride transport and its regulation from simple plants to higher animals, through morphological, physiological and biochemical perspectives.

An additional point of interest is new kinetic models for chloride transport that reflect discrete anatomical loci in the tissue and/or heterogenous cell populations. This book is suitable for graduate students and research workers in the field of biochemistry, biophysics, zoology, botany, biology, neurobiology, pharmacology, agriculture and the medical sciences.

1984 468 pages
Price: US $ 113.50 / Dfl. 295.00

Highlights in Receptor Chemistry

Proceedings of the 2nd Camerino Symposium on Recent Advances in Receptor Chemistry held in Camerino, Italy, 5-8 September, 1983

edited by **C. MELCHIORRE** *and* **M. GIANELLA**

This proceedings volume provides an up-to-date collection of recent developments in the area of receptor chemistry. Particular attention is given to: receptors of the nervous sytem; SAR studies; receptor isolation; receptor topography; biochemical consequences of receptor occupancy and receptor theory. The multidisciplinary approach ensures an overall view and brings together the recent results of leading researchers from a number of diverse disciplines, including chemistry, biochemistry, pharmacology, biophysics, physiology and mathematics.
This volume will be of great interest to pharmacologists, biochemists, neurologists and medicinal chemists. It will also be a valuable source of reference to medical students and post graduate students in related fields.

Fatty Acid Metabolism and its Regulation

edited by **S. NUMA**

NEW COMPREHENSIVE BIOCHEMISTRY, Vol. 7

General editors: **A. NEUBERGER** *and* **L. L. M. VAN DEENEN**

Biochemical, molecular-biological and genetic studies carried out during the last decade have considerably improved the understanding of fatty acid metabolism and its regulation. This volume presents the current status of research in this field, laying emphasis on the molecular characterization of the enzymes involved and their regulation.
The chapters contributed by leading scientists in the specific areas will serve those who teach as well as those engaged in research.

1983 216 pages
Price: US $ 49.50 / Dfl. 129.00
ISBN 0-444-80528-1

Selected Topics in the History of Biochemistry

Personal Recollections I

edited by **G. SEMENZA**

COMPREHENSIVE BIOCHEMISTRY, VOLUME 35

series editors: **A. NEUBERGER** *and* **L. L. M. VAN DEENEN** (formerly edited by M. Florkin and E. H. Stotz)

One of the most exciting developments in biological sciences has been their merging with chemistry and physics resulting in the new disciplines of biochemistry, biophysics and molecular biology. As the developments of these new disciplines has been so rapid many of the key discoveries have occurred within the lifetime of a number of prominent scientists in the field.
The chapters in this and in future volumes are meant to complement the personal recollections by these scientists, the History of Biochemistry in this series (vol. 30-33 by M. Florkin and Vol. 34 by E. Schoffeniels and P. Laszlo). These bibliographic and autobiographic chapters convey to the reader lively, albeit at times subjective, views on both the scientific and social environments of the authors.

Astronomy Express

Editor: Michael Hoskin *Churchill College, Cambridge*

This important new rapid-publication monthly for astronomers will be launched in July.

Astronomy Express aims to

- ★ publish up-to-the-minute information on significant new findings in astronomy, astrophysics and planetary sciences
- ★ feature news of current developments and trends as well as full-length research papers
- ★ utilise streamlined submission and refereeing procedures to ensure *speed of publication*
- ★ use quality paper to allow good reproduction of photographs

Astronomy Express gridsheets conform to the I.A.U. format, no page charges are made, and contributors receive a free supply of offprints. *Circle no. 6 on the Reader Service Card or write to the Press for gridsheets and subscription information.*

Volume 1 July – December 1984
Volume 2 January – June 1985
Volume 3 July – December 1985

Institutional rates
one volume – **£30.00/$67.00**
two volumes – **£60.00/$135.00**

Special Introductory offer!
three volumes **£75.00/$169.00**

Individuals rates
one volume – **£15.00/$32.00**
two volumes – **£30.00/$65.00**

Special introductory offer!
three volumes **£37.00/$81.00**

ISSN 0265-5265

Two good ideas from Cambridge!

BioEssays

ICSU PRESS

Editor-in-Chief: W. J. Whelan *University of Miami*
Staff editor: Adam Wilkins *C.U.P. England*

This major new current-awareness monthly will provide biological scientists with the results of major discoveries at the very frontiers of molecular, cellular and developmental biology.

BioEssays

- ★ meets the growing demand for a publication devoted to reviews, comment and the rapid interchange of biological ideas
- ★ covers the medical, industrial and agricultural implications of primary developments in the new biology
- ★ welcomes illustrated (black and white, and 2-colour) reviews for publication

Circle no. 7 on the Reader Service Card or write to the Press for more details.

traceable temperatures

J.V. Nicholas and D.R.White

now provides a much needed straightforward and readable introduction to temperature measurement and calibration.

"This book will do much to assist those entering the field of temperature measurement and calibration."
P. B. Coates in Journal of Physics E

"The book contains a wealth of practical information on the subject, invaluable to both the experienced scientist and the unskilled neophyte."
Laboratory News

Part A is a basic course in thermometry, intended for reading in its entirety:

- Traceability
- Uncertainty in measurement
- Calibration methods
- Platinum resistance thermometry
- Temperature scales
- Liquid-in-glass thermometry
- Thermocouple thermometry
- Using the thermometer

Part B gives selected topics an extended and more mathematical treatment:

- Thermodynamics
- Treatment of errors
- Resistance measurement
- Heat transfer
- Thermistors, solid state detectors, radiation pyrometers, resonance thermometers, etc.

"Traceable Temperatures" should help in understanding many test specifications as well as providing a basis for formulating test procedures. Particular emphasis has been attached to the needs of testing laboratories seeking registration under a laboratory accreditation scheme. The methods given in the book should be capable of adoption by even very small-scale laboratories.

"Although the book is based on New Zealand practice, this is of little disadvantage to readers in other countries, as the practice is firmly based on British, American, and International standards. The intentions of the authors are carried out in a competent and effective way, and 'Traceable Temperatures' should be a useful addition to the library of any laboratory where temperature measurements are made. It is, moreover, a very well produced book that is a pleasure both to handle and to read."
Rostron Hindley in Laboratory Practice

226 pp, 96 illustrations including halftones and diagrams, cloth.

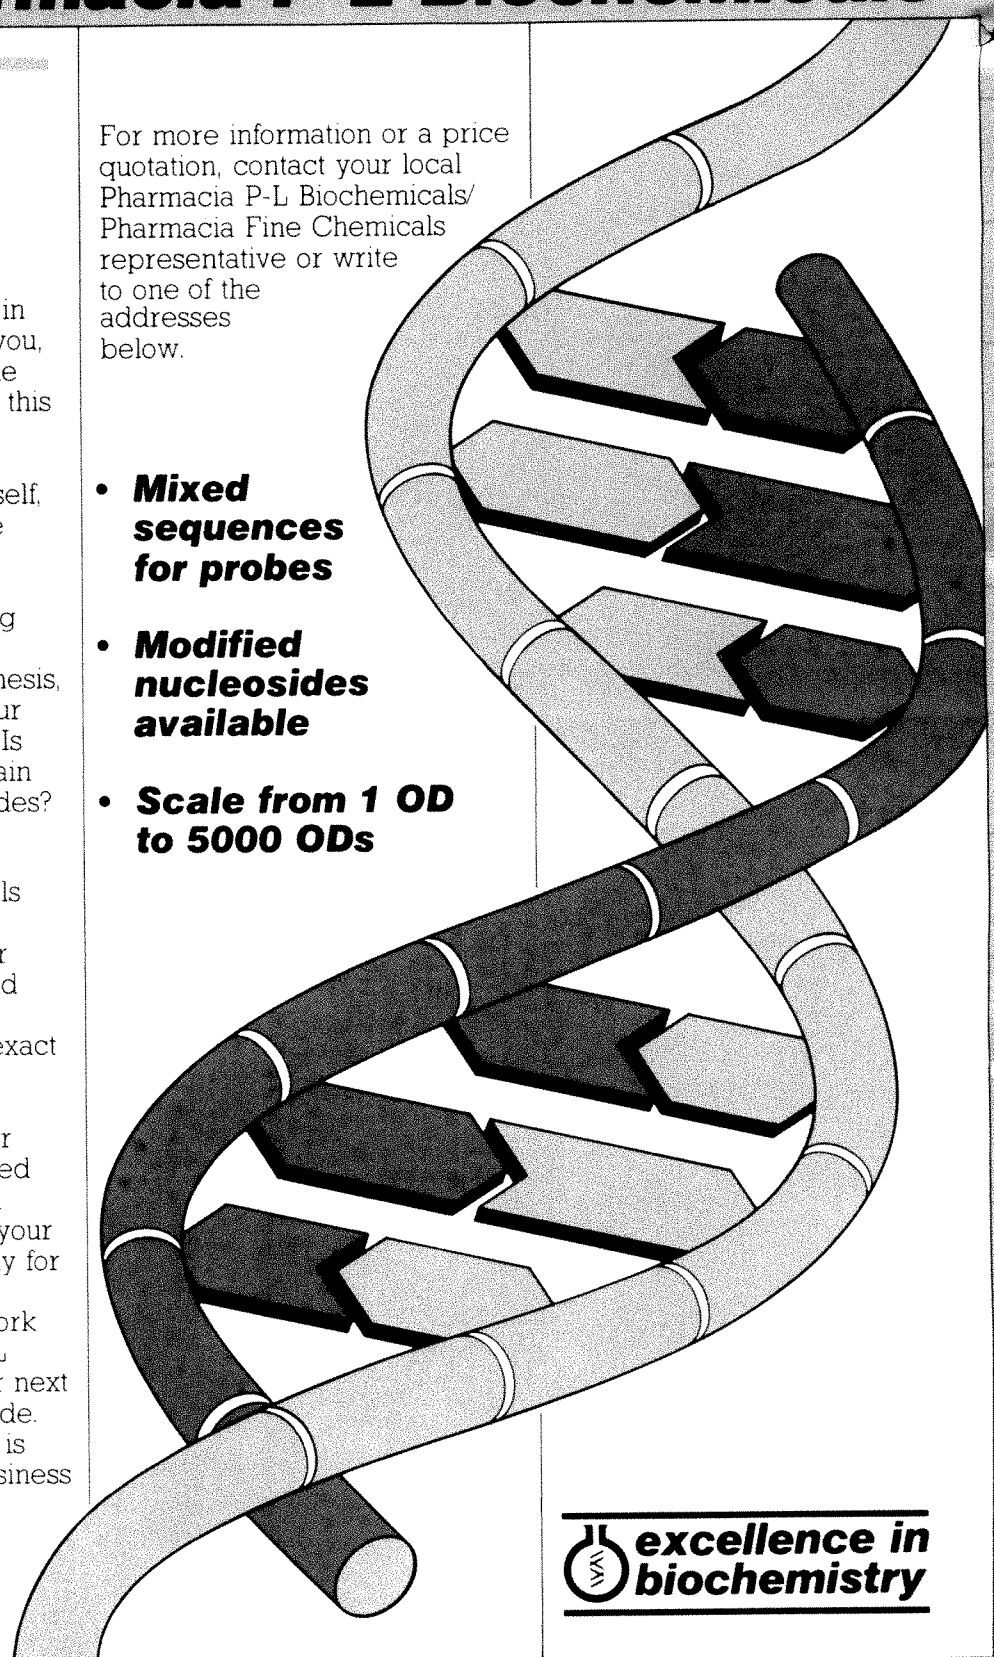
Custom Oligodeoxynucleotides From Pharmacia P-L Biochemicals



Make Discoveries, Not Reagents

Oligodeoxynucleotides of defined sequence are an increasingly important tool in research. This means that you, the researcher, must ask the question: "Where can I get this vital product?". You could synthesize and purify the oligodeoxynucleotide yourself, but this takes valuable time away from your research; instead of making new discoveries, you are making reagents! Expensive "gene machines" can do the synthesis, but you must still invest your time to purify the product. Is there no better way to obtain custom oligodeoxynucleotides?

The better way is to have Pharmacia P-L Biochemicals prepare your custom oligodeoxynucleotides. Our experienced team of skilled professionals can quickly synthesize and purify the exact sequence desired in the quantity that you require. Whether you need 1 OD or 5000 ODs, whether you need modified bases or a mixed sequence, we can supply your oligodeoxynucleotide ready for you to use. Put our custom synthesis experience to work for you—let Pharmacia P-L Biochemicals prepare your next custom oligodeoxynucleotide. Remember, your business is scientific research; our business is making your reagents.

For more information or a price quotation, contact your local Pharmacia P-L Biochemicals/ Pharmacia Fine Chemicals representative or write to one of the addresses below.

- **Mixed sequences for probes**
- **Modified nucleosides available**
- **Scale from 1 OD to 5000 ODs**

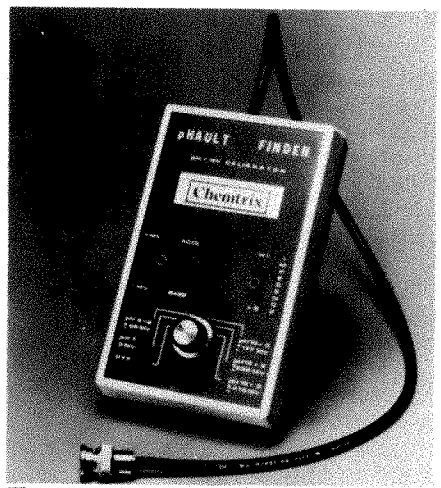
Serum components from NCI

One of fifteen new products this week is a system based on Edman degradation which will detect amino acids at 1 pmol. And NCI announces the availability of serum components.



● Two new nonisotopic assays for monitoring thyroid function have been announced by Syva, the Syva Advance thyroxine assay and the Syva Advance T-3 uptake assay. Using fluorescence energy transfer immunoassay (FETI), the assays are designed to run on the Syva Advance system The thyroxine assay measures total (protein-bound and unbound) thyroxine in serum. The T-3 uptake assay measures human-serum binding capacity for thyroid hormone. The assays require only a small sample size (25 μl for thyroxine; 40 μl for T-3 uptake), and both assays use a simple two-point calibration.
Circle No. 100 on Reader Service Card.

● The Gilson 401 dilutor is a single-syringe diluter that dispenses, pipettes and dilutes with very high accuracy and precision for liquid sample handling. In addition to the usual performances expected from an automatic and programmable dilutor, the Gilson 401 will perform sequential dilutions, aspirate up to 12 different samples in a single cycle, split an aspirated volume of reaget into up to 12 fractions and function in "reverse pipetting" mode to eliminate the risk of cross contamination. Programming is via a simple keypad controller and its microprocessor based ciruitry can store up to 90 programs for easy access. This dilutor may also be externally controlled from a computer.
Circle No. 101 on Reader Service Card.

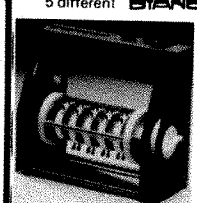
● A comprehensive reference list is available from Vector Laboratories covering 120 publications using the ABC immunoperoxidase staining system. In addition to light microscopy with polyclonal antibodies on parrafin sections, applications include staining of frozen sections, cytocentrifuge preparations, solid phase enzyme immunoassays, nitrocellulose blots, and pre- and post-embedding EM using monoclonal antibodies, lectins and biotinylated polynucleotide hybridizing probes.
Circle No. 102 on Reader Service Card.

● The derivatizing reagent phenylisothiocyanate (PITC), the major reactant in the Edman degradation procedure for sequencing proteins and peptides, has been modified by Waters Associates to provide a new HPLC technique for amino acid analysis. Termed PICO-TAG, the new method offers 1 picomole detection in analysis of primary and secondary amino acids in only 15 minutes.
Circle No. 103 on Reader Service Card.

These notes are based on information provided by the manufacturers. For further details circle the appropriate numbers on the Reader Service Card bound inside the journal.

The new pH/mV calibrator from Chemtrix.

● An extensive range of avidin conjugates for use in indirect immunoassays is available from Tago Inc. The avidin conjugates are now available with FITC, rhodamine, Texas Red, horseradish peroxides, alkaline phosphatase, or beta-galactosidase. Quality performance is confirmed by ELISA testing and histological microscopy. These new avidin conjugates are companion products to a wide line of biotinylated xenogenic affinity-islolated antibodies and $F(ab')_2$ fragments specific for human, mouse, rat, rabbit or pig Ig.
Circle No. 104 on Reader Service Card.

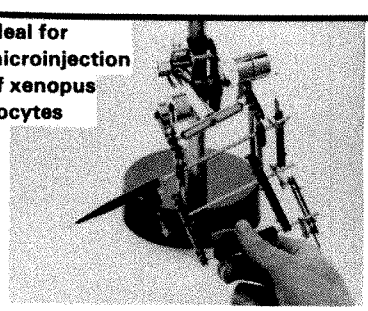


● The new Kratos MS 25 RFA mass spectrometer features new magnet technology, faster scanning capabilities and a higher mass range than previous models. The fast scanning (0.1s) magnet permits acquisition of high quality spectra from extremely narrow GC peaks, and the higher mass range of >3,000 AMU at 1 kV delivers high quality high mass spectra when used in conjunction with a fast atom bombardment source. Combined with the new DS 90 colour graphics data system, the MS 25 RFA offers levels of performance, previous available only using more expensive high resolution GC/MS systems.
Circle No. 105 on Reader Service Card.

● The Chemtrix "pHault Finder" is a hand-held *p*H checker which can quickly and accurately test the calibration, temperature compensating circuits, input impedence and millivolt output of a *p*H meter. This unit stimulates the input from a *p*H electrode in *p*H units, 0 to 14 *p*H or mV units, +355 to −414 mV units. For each unit change in *p*H, the millivolt reading shifts ±59.1 mV units. Additionally, the automatic and manual temperature compensating circuits of a meter may be verified with the pHault Finder in 25°C steps between 0° and 100°C.
Circle No. 106 on Reader Service Card.

● The VG Instruments PlasmaQuad is a powerful new system for elemental analysis combining an inductively coupled plasma with a high-resolution quadrupole mass spectrometer (ICP-MS). The ICP-MS technique gives cleaner spectra than other analytical methods for lower limits of detection and low noise levels.
Circle No. 107 on Reader Service Card.

ADVERTISEMENTS



DIANORM -GD-1 new!
5-Cell Equilibrium Dialyzer
for (ligand) binding and distribution studies under standardized conditions.
5 different DIANORM® – rotating-cell-types (PTFE) are available: minimal volumes 0.125, 0.6, 0.7, 1.5, 3.0 ml. Equilibrium reached in 15-180 minutes. Voltage of the drive is transformed down to 14 V thereby avoiding any risk when using a temperature controlled water bath.

ONE-STEP PROCEDURE PURIFIES

MONOCLONALS

Bio-Rad's DEAE Affi-Gel® Blue has been used successfully to purify rabbit and human IgG from whole serum. Now it's been reported[1] that this same one-step chromatographic procedure can be used to purify mouse monoclonal antibodies directly from ascites fluid under mild conditions–pH 7.2. The resulting IgG fraction is free of protease and nuclease activity and is stable to long term storage. The authors include a chromatogram (Fig. 1) showing the separation of IgG_1. The procedure is also effective for IgG_2.

1. Bruck, C., Portetelle, D., Gilneur, C. and Bollan, A., *J. Immunol. Methods*, **53**, 313 (1982).

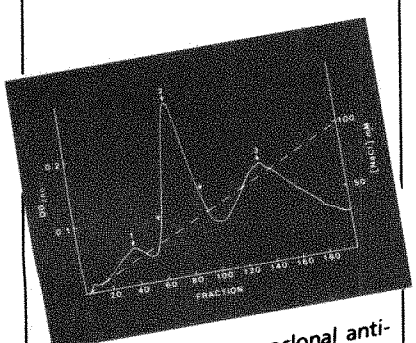

Fig. 1 Elution of monoclonal anti-urokinase antibodies (IgG_1) from a DEAE Affi-Gel Blue column.

Circle No.02 on Reader Service Card.

● The new brain slice chamber from Medical Systems Corporation of Great Neck, New York features a single base unit and two interchangeable top units. The Haas top configuration utilizes semi-submersion techniques, providing good stability for intracellular recording and rapid exchange for perfusion fluids. The Zbicz top is designed to maintain viable slices of tissue submerged under a constant flow of perfusing liquid. A range of techniques can be used for evaluation of drug actions. Cell longevity of 10 or more hours is possible. A companion temperature controller is offered which functions with either top chamber and regulates temperature 30°–40° ± 0.2°C.
Circle No. 108 on Reader Service Card.

● Dynatech Laboratories' AM572A multi-purpose Autowash washer/aspirator can deliver wash fluid and aspirate a complete 96-well MicroElisa plate in 60–90 seconds, depending on the specific test requirements. The machine is therefore suitable for the smaller laboratory with a limited through-put of Miro-Elisa tests as well as being capable of handling the demands of the large-scale user. It can also be used in certain RIA and blood-transfusion applications. A simple but accurate depth adjustment on the wash/aspirate manifold makes the AM52A Autowash particularly suited to working with tissue culture monolayers.
Circle No. 109 on Reader Service Card.

● A new test kit for the determination of angiotensin converting enzyme (ACE) in serum is available from Boehringer Mannheim. The colorimetric assay is based on the ability of ACE to convert hippuryl-glycyl-glycine into glycyl-glycine which is converted to trinitrophenyl-glycyl-glycine by trinitrobenzylsulphonate. The absorbance of trinitrophenyl-glycyl-glycine is measured at 420 nm. The test requires a sample of only 10 μl.
Circle No. 110 on Reader Service Card.

● Very low levels of NADH and NADPH can be detected using the new LKB bioluminescent assay. The reagents use bacterial luciferase coupled to a specific oxidoreductase enzyme. There are therefore two reagents, one for NADH, the other for NADPH. These reagents give a vastly improved (1,000-fold) sensitivity compared with spectrophotometric assay for NADH, NADPH and associated enzyme assays. An application paper is available from LKB.
Circle No. 111 on Reader Service Card.

● New from Cruachem, ColorTAG monomers can be used during the synthesis of a mixed DNA probe to determine the success or failure of a mixed addition. The deprotection effluent from each of the monomers is a distinctive colour and so the actual nucleotide ratio at a degenerate site can be determined by visible spectroscopy. This provides confirmation that all possible sequences are indeed present in a mixed probe.
Circle No. 112 on Reader Service Card.

● For decontamination of laboratory glassware used with radioactive solutions, ICN Radiochemicals is marketing Dekasol. After a 24-hour soak at room temperature in 5% Dekasol and distilled water, residual activity for carbon-14, tritium and phosphorus-32 is usually 0.2% of the original activity. For more stubborn radioactive substrates, such as those containing iron-49 and iodine-131, soaking in a 20% solution of Dekasol at 50°C for 2 hours provides effective decontamination.
Circle No. 113 on Reader Service Card.

● Zetabind is a charge-modified membrane matrix for DNA, RNA and protein transfer applications. Manufactured by AMF Cunuo, Zetabind is composed of charge modified nylon 66 which results in an electrostatic adsorption of anionic macromolecules. Binding capacities of 480 $\mu g\ g^{-1}$ have been reported and this highly efficient binding permits re-use of transfers for re-probing. Zetabind, unlike DBM and DPT papers, does not require chemical activation and can be stored indefinitely at room temperature. Efficient binding of anionic macromolecules in low salt buffers permits electrophoretic transfers from gels. It also provides enhanced binding for capillary blots.
Circle No. 114 on Reader Service Card.

Frozen serum panels from NCI

A VARIETY of serum components (including peptide hormones, viral antigens, isoenzymes, glycoproteins, antibodies, immune complexes, tumour-associated antigens, carbohydrates, phospholipids and nucleotides) have been reported to be useful in cancer diagnosis and/or in monitoring cancer treatment or recurrence. The US National Cancer Institute is interested in evaluating serum assays that are potentially useful in the diagnosis of cancer. Coded panels composed of 1 ml aliquots of pretreatment frozen sera from patients with various neoplasms, from benign disease patients and from healthy controls are available to investigators to evaluate assays in which preliminary results indicate the ability to discriminate between cancer patients and controls. Promising results may form the basis for a subsequent grant application. Preliminary data documenting a useful test must be submitted and should include: a brief description of the assay, results of patients with cancer, results of patients with non-malignant disease, results in healthy control subjects and reprints of published work, if available. Request for a coded serum panel should be sent to: Diagnosis Serum Panels, Project Officer, NCI-Serum Bank, Diagnosis Branch, Westwood Bldg., Room 10A10, 5333 Westbard Avenue, National Cancer Institute, National Institutes of Health, Bethesda, MD 20205. □

BIOTECHNOLOGISTS!

YOU NEED FAST AND THOROUGH COVERAGE OF RESEARCH, FINANCE, REGULATION, MARKETING AND GOVERNMENT POLICY ... WHEREVER IT TAKES PLACE.

Where can you turn to get the crucial information you need – and get it all in one stimulating publication?

Join thousands of your associates in leading corporations and institutions who benefit each month from the largest and most influential publication of its kind.

... SUBSCRIBE TO **BIO/TECHNOLOGY**
The International Journal of Biology and Industry

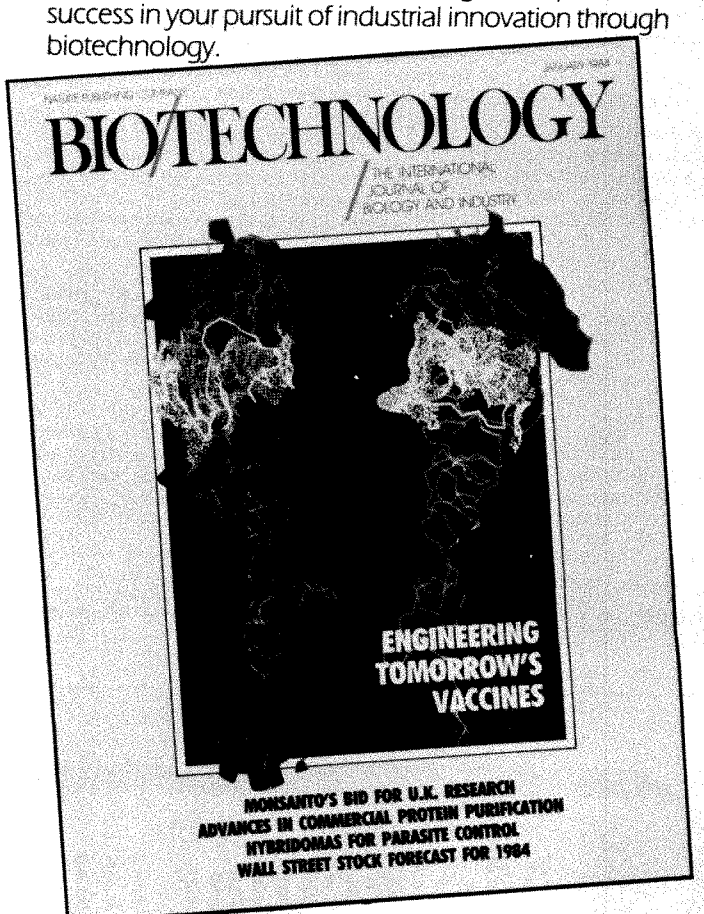
In every monthly issue, you'll find:

News reports
From correspondents around the world. New ventures, marketing agreements, research breakthroughs, new patents, government activities and types of information about your competitors that you won't find in any other publication.

Feature articles
Examining in detail new discoveries and techniques as they apply to health care, foods and beverages, chemicals, agriculture, animal health, energy and environmental management.

Profiles of leading corporations
In-depth studies of the leaders in the field.

Original research papers and reviews
Contributed each month by noted researchers in academia and industry.



Technology reports
From renowned experts in microbiology, chemical engineering, marketing, finance and government policy.

International patents
Recently issued from around the world are rapidly searched, edited and published each month.

New resources and tools of biotechnology
Presented and discussed as soon as they become available.

In just one year, **BIO/TECHNOLOGY** has become the authoritative forum for the crucial ideas, analysis and information needed for innovative research and profitable product development in biotechnology.

SUBSCRIBE TODAY to achieve the greatest possible success in your pursuit of industrial innovation through biotechnology.

UNIVERSITY OF OTAGO
Dunedin, New Zealand

CHAIR OF MATHEMATICS

The University Council invites applications for appointment to the Chair of Mathematics at present occupied by Professor D B Sawyer who will retire at the end of 1984.

Applicants should possess a substantial research record and good administrative and teaching ability. Candidates in any area of specialisation will be considered but preference will be given to candidates whose interests are centred in the main body of Mathematics.

Professional salaries at present provide for a salary within the range of NZ$41937 to NZ$52182 per annum. In addition, a cost of living allowance of NZ$417 per annum will be paid.

Further particulars are available from the Secretary General, Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF, or from the Registrar, University of Otago, PO Box 56, Dunedin, New Zealand.

Applications close on 31 August 1984. (2206A)

BILLERICAY BURNS RESEARCH TRUST

SENIOR RESEARCH FELLOW

Applications are invited for a Senior Research Fellow for a project in burns research. Considerable experience in independent research will be required. The Fellow will be expected to pursue not only his own project but also to give advice and guidance on their research projects to surgical staff at this Regional Centre for Plastic Surgery and Burns.

The Fellow's research project might be in the structural, biochemical, pharmacological, physiological or experimental pathological fields.

It is envisaged that the Fellow would be of a status such as would enable the Trust to seek for him or her an honorary university appointment in one of the University of London Medical Schools.

Further details may be obtained from: A F Wallace, FRCS, NE Thames Regional Plastic Surgery Centre, St Andrew's Hospital, Billericay, Essex. (2175)A

BRISTOL POLYTECHNIC
SCIENCE DEPARTMENT

RESEARCH ASSISTANT — Ref No R/34

Applications are invited from honours graduates in Biological Science or from candidates completing their degrees this Summer for the post of Research Assistant to Dr A Vivian, Reader in Biotechnology, to investigate the Genetics of Host specificity in Pseudomonas pisi.

This is a 3 year project funded by the Agricultural and Food Research Council and the successful candidate would be expected to register for a higher degree.

Salary Scale: £5,415 — £6,123 per annum.

For further details and an application form, to be returned by 11 June 1984, please contact the Personnel Office, Bristol Polytechnic, Coldharbour Lane, Frenchay, Bristol or ring Bristol 656261, ext 216 or 217.

Please quote Reference Number R/34 in all communications. (2180)A

THE FLINDERS UNIVERSITY OF SOUTH AUSTRALIA
SCHOOL OF PHYSICAL SCIENCES
RESEARCH ASSOCIATE

Applications are invited for a position as Research Associate in the School of Physical Sciences. This position is supported by the Department of Resources and Energy for work on the development of new heterogeneous catalysts for the production of hydrocarbon fuel. Applicants should have a PhD and relevant research experience in catalysis or solid state chemistry.

The appointment will be made in the salary range $A22,212-$A26,536 (under review) according to qualifications and experience and will be until June 1986 in the first instance. Further information may be obtained from Professor B G Baker, Tel (08) 275-2288.

Applications, including full personal details, details of academic record, experience and publications, and the names and addresses of at least two referees, should be sent to the Registrar, The Flinders University of South Australia, Bedford Park, South Australia 5042, by 30 June 1984. Applicants are requested to ask their referees to forward their reports direct to the Registrar before the closing date. (2202)A

Molecular Biologist
Beckenham, Kent

The Wellcome Foundation Limited is a major group of pharmaceutical and chemical companies with headquarters in the UK and a turnover close to £700m.

We now have an opportunity for a post doctoral scientist to join our Department of Molecular Biology, which comprises some 16 scientists plus technical support, and is involved in fundamental research into the cause and prevention of disease.

You will be joining a group studying surface antigens of malaria parasites and should be experienced in recombinant DNA techniques and capable of independent work but, be prepared to collaborate with other scientists.

We offer a salary not less than £10,000, dependent on experience and ability. Excellent benefits include five weeks' holiday, subsidised restaurant, first class sports and social facilities and generous assistance with relocation expenses where appropriate.

Please write with full CV, and quoting reference WRL/ 280, to Mrs A. Bowker, Personnel Officer, The Wellcome Research Laboratories, Beckenham, Kent BR3 3BS.

(2173)A

Wellcome

UNIVERSITY OF ARIZONA
RESEARCH ASSOCIATE POSITION

To work in a human tumor biology laboratory. 50% time to oversee cell culture activities and 50% time to develop own program. Chance to become an independent investigator.

Formal training (PhD and post-doctoral experience) in cell culture and/or cell biology required. Experience in biochemical, experimental therapeutics, immunological, or molecular techniques useful but not required.

Salary commensurate with training and experience. Send curriculum vitae and three references to: F Meyskens, Jr, University of Arizona Cancer Center, 1501 N Campbell Avenue, Tucson, AZ 85724.

University of Arizona is an Equal Opportunity/Affirmative Action Employer. Closing date Aug 1, 1984. (NW555)A

UNIVERSITY OF READING

DEPARTMENT OF PHYSIOLOGY & BIOCHEMISTRY

GRADUATE RESEARCH OFFICER

required to work on a project concerned with the endocrine regulation of nutrient supply and utilisation in sheep. The position is funded by the Agriculture and Food Research Council for a fixed period of two years.

Salary in range £6,310 — £7,190 pa. Candidates should have a good honours degree in Animal Physiology, Nutrition or a related subject.

Apply, quoting Ref R23A, for application form and further details to Personnel Office, University of Reading, Whiteknights, Reading RG6 2AH. (2186)A

UNIVERSITY OF EDINBURGH

FACULTY OF MEDICINE

CHAIR OF PHARMACOLOGY

Applicatons are invited for the Chair of Pharmacology in the Faculty of Medicine in the University of Edinburgh.

The Professor of Pharmacology will be expected to provide academic leadership as Head of Department, to promote and conduct research and to participate in undergraduate and post graduate teaching.

The salary will be at the pre-clinical professorial level (minimum £17,910 per annum).

Further particulars may be obtained from the Secretary to the University, University of Edinburgh, Old College, South Bridge, Edinburgh, EH8 9YL, with whom applications (15 copies), including curriculum vitae and the names and addresses of three referees should be lodged not later than 31st July, 1984.

Please quote reference no 22/84. (2165)A

Commonwealth of Australia
Department of Defence
Canberra

SENIOR DEFENCE OFFICER

(Nuclear Development Analysis)

$A27952-29048

The Australian Department of Defence invites applications from suitably qualified men and women for the position of Senior Defence Officer in the Joint Intelligence Organisation located in Canberra.

Canberra, the national capital, with a population of 220,000, is a modern city situated in pastoral surroundings approximately 200 kilometers inland from the major port of Sydney. It enjoys a temperate climate and is within driving distance of seasonal summer and winter recreational areas. The city offers excellent community facilities particularly for those with a young family.

The Joint Intelligence Organisation is responsible for the preparation of reports and strategic estimates, both of a long term and current nature, on a wide range of subjects of a defence interest, mainly in the Asia-Pacific region.

The successful applicant for this position will carry out documentary research and prepare reports on foreign nuclear research, development and production.

Qualifications in science or engineering at a tertiary level and several years experience in the nuclear industry or research fields are desirable.

Conditions of service include four weeks annual leave with a bonus payment, cumulative paid sick leave, maternity leave after a qualifying period, three months long service leave after ten years continuing service and a comprehensive superannuation scheme. Fares and removal expenses to take up duty and settling-in allowances are payable in some circumstances.

Applications giving full details of qualifications, relevant experience and employment history, together with recent references and telephone numbers of referees, should be forwarded to: Mr. R. Rankin, Personnel Services, Third Floor, Australia House, Strand, London WC2B 4LA (Tel: 01-438 8829) by 29th June, 1984.

(2229)A

AUSTRALIA

BIO-COM

BIO-COM (U.K.) LIMITED

Bio-Com seeks for international research associates young independent and ambitious scientist with strong friendly personality, interested in both fundamental and development research. Training: immunology, genetic engineering, peptide-nucleic acid characterization. Initially based at Paris Institution, hence, conversational French essential. Willing to travel/relocate UK/USA. Starting salary £9,000 — £12,000.

Send cv, photograph and manuscript letter to the Director of Research, Bio-Com (UK) Ltd, 34 Floral Street, London WC2E 9DJ.

(W945)A

WELLCOME BIOTECHNOLOGY LIMITED, FMD DIVISION, PIRBRIGHT

SENIOR LABORATORY TECHNICIAN

A vacancy has arisen for a Senior Laboratory Technician to join our Research Team in the Foot and Mouth Disease Virus Section at Pirbright. This Section is part of our Department of Virology R&D at Beckenham and there is considerable interaction with other Biological Research Departments as well as collaboration with external organisations.

Applicants should be highly motivated, educated to degree or HTEC level and have the practical experience to provide full technical expertise required to general full length DNA clones of Foot and Mouth Disease Virus RNA. To obtain infectious virus from such clones and to perform site directed mutagenesis.

The post will attract a competitive salary and excellent benefits including 5 weeks holiday, life assurance, sick pay and pension scheme.

Please write with full details to: Mr. K. Tollett, Wellcome Biotechnology Limited, FMD Division, Ash Road, Pirbright, Woking, Surrey GU24 0NQ. (1905)A

CSIRO

AUSTRALIA

STATISTICIAN (SIGNAL ANALYSIS)

$A25,342-$A37,274

DIVISION OF MATHEMATICS AND STATISTICS CANBERRA ACT

CSIRO conducts scientific and technological research in laboratories located throughout Australia and employs about 7,500 staff, of whom some 2,900 are professional scientists. The Organization's research activities are grouped into five Institutes: Animal and Food Sciences, Biological Resources, Energy and Earth Resources, Industrial Technology and Physical Sciences. The CSIRO Division of Mathematics and Statistics is a member of the Institute of Physical Sciences.

The Division of Mathematics and Statistics has a staff of 97, including 75 professional scientists. The Division's Headquarters are at Canberra, and there are Regional Offices located at Melbourne, Sydney, Adelaide, Brisbane and Perth. Scientists of the Division provide advice on the statistical, mathematical and numerical aspects of research projects undertaken by scientists in other CSIRO Divisions, as well as conducting basic research in statistic and mathematics.

The Division has a program in Signal Analysis and wishes to consolidate and expand this program's work in Image Analysis. The appointee will be required to direct the Division's research and consulting in this area. The appointee will be located in Sydney but may be required to visit other cities in Australia to initiate and direct collaborative work with scientists in other Divisions in CSIRO.

Applicants should have a PhD degree or equivalent qualifications in a relevant branch of statistics together with research and consulting experience in at least one of the fields of geometrical probability, mathematical morphology or stereology.

The position is available for a term of five years and Australian Government superannuation benefits are available.

APPLICATIONS: Stating full personal and professional details, the names of at least two referees and quoting reference No A3591, should be directed to:

The Chief
CSIRO Division of Mathematics and Statistics
GPO Box 1965
CANBERRA ACT 2601
AUSTRALIA

By June 29, 1984.

CSIRO IS AN EQUAL OPPORTUNITY EMPLOYER

(W1021)A

SENIOR ANIMAL SCIENTIST

The Sub Humid Zone Programme of the International Livestock Centre for Africa, Kaduna, Nigeria, seeks a SENIOR ANIMAL SCIENTIST with qualifications and experience in cattle production but who should also have a strong interest in small ruminants and methods of pasture management. The programmes work is focussed on mixed farming systems and the interface between pastoral and agricultural communities in the sub-humid zone of West Africa. There is a strong emphasis on the use of legumes for forage improvement in these systems.

We are seeking an individual who can work as part of a small interdisciplinary team with a farming systems research approach and who is able to develop innovative approaches to research on small holder and pastoral animal production systems. An interest between nutrition health and production is essential. West African experience and French language are highly desirable.

Salary and related benefits are negotiable in line with comparable International Organisations.

Applications should airmail personal history and names of three referees to:

The Director General,
ILCA, P.O. Box 5689 — Addis Ababa, Ethiopia

to reach him before July 31, 1984. (W1023)A

UNIVERSITY OF EDINBURGH

DEPARTMENT OF PHYSICS

Applications are invited for the post of

UNIVERSITY DEMONSTRATOR

in the Department of Physics from 1st October 1984 for a period of 3 years. The appointee will be expected to contribute to the Department's teaching and to join in the work of one of the research groups; preferably that of the experimental condensed matter group.

The appointee will probably already have a PhD degree and the salary will be in the range £6,310 — £9,425 dependent upon age and experience, together with normal pension arrangements.

Applications, including the names of two referees, should be submitted to Professor R A Cowley, University of Edinburgh, Department of Physics, Mayfield Road, Edinburgh EH9 3JZ, from whom further particulars can be obtained.

Please quote reference No 1135. (2194)A

UNIVERSITY OF READING

WELCOME TRUST LECTURESHIP

DEPARTMENT OF PHYSIOLOGY & BIOCHEMISTRY

Applicants should have research experience in the physiology of the fetus or newborn, and an interest in the neurophysiology of development would be an advantage. The appointment is from 1 October 1984 for three years and may be renewed for a further two years subject to satisfactory review.

Applicants should not be more than 35 years old or holders of a tenured post. Current Lecturer's salary £7,190 to £14,125 pa.

Further particulars and application forms (2 copies) are available from the Personnel Officer, University of Reading, Whiteknights, Reading, RG6 2AH, Tel (0734) 875123 ext 220. Please quote Ref AC 8413. Closing date 18 June 1984. (2157)A

UNIVERSITY OF NOTTINGHAM

LECTURER IN ZOOLOGY

Applications are invited for the post of Lecturer in Zoology which will become vacant on 1st September 1984. Candidates will be expected to have research experience in behavioural and/or applied fields of Insect Biology.

Salary will be within the range £7,190 — £14,125 per annum.

Application forms and further particulars, returnable not later than 18 June 1984, may be obtained from the Staff Appointments Officer, University of Nottingham, University Park, Nottingham NG7 2RD. Ref no 948. (2178)A

UNIVERSITY OF LIVERPOOL

DEPARTMENTS OF IMMUNOLOGY AND BIOCHEMISTRY

Applications are invited for the post of

SENIOR RESEARCH ASSISTANT

in the Department of Biochemistry to work on an investigation into gene cloning of human oncotrophoblast antigens defined by monoclonal antibodies. This work has important implications for our understanding of materno-foetal interactions as well as the process of oncogenesis. This is a post-doctoral postion for which experience in recombinant DNA techniques would be a strong advantage.

Initial salary within the range £7,190 — £8,080 per annum.

Applications, together with the names of three referees, should be received not later than 25th June, 1984, by the Registrar, The University, PO Box 147, Liverpool L69 3BX, from whom further particulars may be obtained. Quote Ref: RV/529/N. (2176)A

UNIVERSITY OF GLASGOW

DEPARTMENTS OF BIOCHEMISTRY AND MEDICAL CARDIOLOGY

GRADUATE RESEARCH ASSISTANT

A vacancy exists for a graduate with a good degree in Biochemistry or Molecular Biology to work on a project to investigate control of energy metabolism in the heart. Salary will be on Range 1B of the scales for Research and Analogous Staff (£6,310—7,630).

Applicants should send their CV and the names of two academic referees to Dr Jocelyn Dow, Department of Biochemistry, University of Glasgow, Glasgow, G12 8QQ, to arrive not later than 8th June, 1984.

In reply please quote Ref No 5264M. (2167)A

CHRISTIE HOSPITAL AND HOLT RADIUM INSTITUTE

PATERSON LABORATORIES

RESEARCH TECHNICIAN/ SENIOR RESEARCH TECHNICIAN

For work in a Histopathology Laboratory providing a service to biological research units.

Qualifications: HNC in Medical Laboratory Sciences (Histopathology) or equivalent experience.

Salary: £5,491 — £7,747 or £7,997 — £9,507 pa according to age, qualifications and experience.

Applications to Laboratory Administrator, Paterson Laboratories, Christie Hospital and Holt Radium Institute, Wilmslow Road, Withington, Manchester M20 9BX quoting reference PL/84/10 and enclosing SAE. (2174)A

UNIVERSITY OF TEXAS HEALTH SCIENCE CENTER AT DALLAS

DEPARTMENT OF RADIOLOGY

POSTDOCTORAL RESEARCH
NMR APPLIED TO TISSUE METABOLISM

Two positions are available to pursue research in physiology and metabolism using the non-invasive method of high resolution nuclear magnetic resonance. The laboratory is currently investigating several aspects of cardiac and brain metabolism using NMR techniques. Research projects in both basic studies and in clinical applications are available. The facilities of the NMR Laboratory are extensive and state-of-the-art and include a one meter bore system under development for clinical use. The laboratory also has an excellent staff to support various aspects of the research. Candidates should have training in biochemistry or physiology. Additional experience in physical and analytical chemical methods is desirable but not essential.

Please send a résumé and three letters of reference to: Ray L. Nunnally, PhD, Director of Biomedical Magnetic Resonance, Department of Radiology, University of Texas Health Science Center at Dallas, 5323 Harry Hines Boulevard, Dallas, Texas 75235.

Equal Opportunity University.
(NW530)A

TRUDEAU INSTITUTE

A Postdoctoral research position in infectious disease

is currently available to study interactions between several intracellular microbial pathogens and the cellular defenses in both normal and immunosuppressed animals. Current research is directed towards understanding cellular interactions responsible for the modulation of delayed-type hypersensitivity and acquired antimicrobial resistance during the development of chronic systemic disease in inbred mice. Candidates should have a strong background in infection-immunity or in immunology.

The Trudeau Institute is a private, not-for-profit basic medical research institution situated on the shores of Lower Saranac Lake, about a mile from the village of Saranac Lake and 10 miles from Lake Placid, NY. On-campus housing is available. Salary is at appropriate NIH levels.

Send curriculum vitae and names of three references to: Dr Frank M. Collins, Trudeau Institute, P.O. Box 59 Saranac Lake, N.Y. 12983. An Equal Opportunity Employer.
(NW525)A

ADVANCED DRUG DELIVERY RESEARCH

Horsham, West Sussex

In line with the policy of Ciba-Geigy Pharmaceuticals to lead the field in technological innovation, a major new research unit dedicated to the discovery and exploitation of new concepts for drug delivery has been established in Horsham. This unit will provide exceptional opportunities for imaginative and highly motivated scientists to carry out original research in a stimulating and challenging environment in collaboration with scientists from a wide range of scientific disciplines.

Applications are now invited for the following positions:

Senior Section Leader in Colloid/Polymer Science

To lead and participate in the creation of a section of the unit responsible for the design and characterisation of novel colloidal drug delivery systems. The applicant should have demonstrated outstanding ability in colloid/polymer science or in a related field. Ref ACP 1

Research Scientists in Colloid/Polymer Science

Positions are available for a scientist having a PhD with, preferably, at least two years post-doctoral experience, and for graduates with a strong background in colloid and surface chemistry/polymer science or a related field. Ref. ACP 2

Research Biologist/Physiologist

To participate in a Section of the Unit responsible for examining the biological aspects of colloidal drug delivery systems. This post offers an unique opportunity to a graduate having a particularly strong background in mammalian biology/physiology to contribute to a multidisciplinary research unit. Ref ACP 3

The salary and benefits package for these positions is very attractive and will include relocation expenses where appropriate.

Applicants for these positions should send a full c.v. and an outline of their research and career expectations, quoting reference, to Miss S.J. Byrne, Personnel Officer, Ciba-Geigy Pharmaceuticals, Wimblehurst Road, Horsham, West Sussex, RH12 4AB.
(2158)A

CIBA–GEIGY

BIOCHEMISTRY: Two tenure-track assistant professors effective from 1 September 1984. Postdoctoral experience and a commitment to teaching and research required. Research areas open, but preferences to neurochemistry and molecular/cell biology. Application deadline: 1 July 1984. Send résumé, research plans, summary of teaching experience, and at least three letters of recommendation to: Chairman, Departmental Affairs Committee, Department of Biochemistry, Emory University, Atlanta, Ga 30322. An Equal Opportunity/Affirmative Action Employer. (NW569)A

MARIE CURIE MEMORIAL FOUNDATION RESEARCH INSTITUTE

Two Post-doctoral positions in Molecular Biology. The first will involve the application of recombinant DNA technology to the study of cellular gene activation by transforming proteins.

The second will investigate the role of the transformation – associated protein p53 in cell proliferation and transformation. Eukaryotic vectors expressing p53 and a variety of mutants are available for this work.

These three-year appointments are available now and salary will be on the Lecturer Scale.

Apply with C.V. and the names of two referees to Dr. G. Currie, Marie Curi Research Institute, The Chart, Oxted, Surrey (088388-3055).
(2163)A

Instrumentation Laboratory's Expansion In Diagnostic Research

Allied, a 10-billion dollar diversified company, has made a major commitment to growth in Human Medical Diagnostics.

This is a new venture focusing on research and development of diagnostic products for human diseases.

The following positions are currently available at Instrumentation Laboratory, Allied's diagnostic company, located in Lexington, Massachusetts.

Scientists

Biochemist

Evaluate biotechnologies having application in in-vitro diagnostic tests including immunodiagnostics, monoclonal antibodies and DNA probes. Design or develop diagnostic tests using technology available within IL or at other Allied divisions. Guide designs through production phase. MS biochemistry with 5-10 years' experience in diagnostics or biotechnology. Knowledge of immunology, monoclonal antibody technology. Job code BCH.

Senior Scientist

We seek an individual with 2 years' minimum hands-on experience operating a florescence activated cell sorter. Background in cell surface immunoflorescence, cell cycle analysis and DNA staining techniques is necessary. Experience screening and sorting hybridomas would be desirable. Responsible for maintenance and calibration of the equipment for own project and that of other investigators as well. MS/Ph.D required. Job code SSF.

Senior Scientist

We seek a Ph.D level scientist to research biological aspects of lymphokines. Requires broadbased experience including T-cell hybridoma methodology. Minimum 2 years' postdoctoral experience. Should include the isolation, purification and bioassays for lymphokines. Particular interest in TCGF (IL-2) and INF, but not restricted to them. Job code SCL.

Principal Scientist

Position involves reagent formulation, stabilization, and optimization. Ph.D. in Chemistry with 6-8 years' experience required. Simplex optimization methodology background a plus. Job code PLS.

IL offers an excellent salary and benefits package. Please forward resume including salary requirements and specifying job code for the position you are interested in to:
Mr. Paul A. Smith, Jr.

Instrumentation Laboratory
113 Hartwell Avenue
Lexington, MA 02173

We are an equal opportunity employer

ALLIED Instrumentation Laboratory

(NW557)A

UMIST/ DARESBURY LABORATORY
SYNCHROTRON RADIATION — POST DOCTORAL POST IN X-RAY SPECTROSCOPY

Applications are invited for a Research Assistant on a project involving the application of X-ray Spectroscopy to the determination of the structure of copper containing enzymes involved in the biosynthesis and metabolism of biogenic amines. The position is tenable from 1st October 1984 and is for a period of three years. He/she is expected to participate in the further development of the EXAFS technique and particularly in the analysis of the near edge fine structure from which detailed three dimensional information around the active sites of the enzymes can be obtained.

Applicants are expected to hold a PhD in Physics, Chemistry or a biological science. Experience with the application of physical methods to biological structure determination would be an advantage.

Commencing salary; £7,630 p.a. on range IA. (under review).

Applications, quoting reference CH/ 78/ AI, including a curriculum vitae and names of two referees should be sent to either Dr N J Blackburn, Chemistry Department, UMIST, PO Box 88, Manchester M60 1QD or Dr S S Hasnain, Daresbury Laboratory, Warrington WA4 4AD. The closing date is 22 June, 1984.

(2190)A

UNIVERSITY OF ABERDEEN
DEPARTMENT OF MICROBIOLOGY
TEMPORARY LECTURESHIP

The Department of Microbiology invites applications for a temporary Lectureship for one year from October 1984. The post arises from the award of a Nuffield Research Fellowship to Dr I R Booth, and the successful applicant will be expected to assist with teaching in microbial physiology, genetics and molecular biology. There will be the opportunity also to carry through a research programme.

Salary within the range £7,190 to £8,530 per annum on Lecturers salary scale (under review).

Further particulars and application forms from The Secretary, The University, Aberdeen, with whom applications (2 copies) should be lodged by 15 June 1984.

(2170)A

UNIVERSITY OF NEWCASTLE UPON TYNE
CHAIR OF SOIL SCIENCE

Applications are invited for the Chair of Soil Science which will become vacant through retirement on 30 September 1984. The post is open to suitably qualified candidates in the field of Soil Science; some preference will be given to those with interests in Soil Chemistry. The appointment will carry the headship of the Department of Soil Science for an initial period of five years.

The appointment will be effective from October 1984 or as soon as possible thereafter. Salary will be at an appropriate point on the range for professional staff which commences at £17,275.

Further particulars may be obtained from the Registrar, University of Newcastle upon Tyne, 6 Kensington Terrace, Newcastle upon Tyne, NE1 7RU, with whom applications (15 copies) giving the names of not more than three referees must be lodged not later than 6 July 1984. Candidates from outside the British Isles may submit one copy only.

(2198)A

MONASH UNIVERSITY
Melbourne, Australia
DEPARTMENT OF BIOCHEMISTRY
FIXED-TERM LECTURER (3-5 YEARS)

Postdoctoral graduate for teaching medical or science students and participation in research in areas of (1) cloning and gene expression in yeast; (2) human interferon biology, as well as genes and expression; (3) yeast mitochondril ATP synthetase complex; (4) monoclonal antibodies and protein chemistry. Enquiries to Professor A W Linnane.

Salary: $A24,353 — $A31,994 pa. Applications including Ref no 30212A, curriculum vitae and 3 referees to the Registrar, Monash University, Clayton, Vic 3168, Australia, with a copy to the Secretary General, Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF, by 9/7/84, from whom Conditions of Appointment are available.

An equal opportunity employer.

(2068)A

UNIVERSITY OF EDINBURGH
FACULTY OF MEDICINE
LECTURESHIP IN PHYSIOLOGY

Applicants must have a good Honours Degree in Physiology and at least three years' research experience.

Salary will be at an appropriate point on the scale £7,190—£14,125. USS Superannuation.

Applications (8 copies) including a full curriculum vitae and the names and addresses of three referees should be sent to the Secretary to the University, University of Edinburgh, Old College, South Bridge, Edinburgh, EH8 9YL by 25th June, 1984, from whom further particulars can be obtained.

The East of Scotland College of Agriculture
The Edinburgh School of Agriculture

Head of Animal Production Advisory and Development and Deputy Head of Animals Division (Ref: 226/ N)

Applications are invited for the above senior post which has substantial responsibilities for the management of Research, Development and Specialist Advisory Work in Animal Production, Animal Production Systems and in the application of new techniques in Animal Science to farming practice.
Candidates should possess a good degree in Agriculture, Animal Production or Animal Science and considerable post-graduate experience in on or more aspects of the work.
The appointment will be on the Scottish Agricultural College's Grade I Level for which the current salary scale is £13,345-£17,748 per annum. The conditions of service are those appropriate to appointments at a similar level in the Civil Service.
Further particulars may be obtained from The Secretary, The East of Scotland College of Agriculture, The Edinburgh School of Agriculture, West Mains Road, Edinburgh EH9 3JG to whom applications in writing, including the names and addresses of three referees, should be submitted not later than 30th June, 1984. Reference 226/ N, should be quoted in all communications.

VISITING RESEARCH Assistant Professor/Post doctoral non-tenure track position available Sept 1, 1984 for Molecular Biologist interested in working on cell-specific gene expression in Caenorhabditis elegans. Individual must have a PhD and expertise in DNA cloning and sequencing. Salary $18,000-$20,000 commensurate with experience and qualifications. Minimal teaching is required, full benefits, renewable yearly up to five years. Send résumé and 3 letters of recommendation to Dr Michael Klass, Biology Department, University of Houston, Houston, Texas 77004. (NW551)A

Cetus Corporation and Cetus Madison Corporation, leaders in the field of biotechnology, are currently seeking candidates for the following positions:

FERMENTATION MICROBIOLOGIST/ ENGINEER #84078

Successful candidates will have an M.S./Ph.D. and have experience in small and large scale fermentation. The position requires self-motivated individuals who are willing to be involved in bridging the gap between laboratory advances and commercial production.

Respond to this position to:

Personnel Dept., Cetus Madison Corp.
8520 University Green
Middleton, WI 53562

SR. SCIENTIST/SCIENTIST #83159

Cetus Corporation is currently seeking qualified Ph.D.'s for our Molecular Cloning Department. Candidates should have a minimum of three years' postdoctoral experience in the area of gene expression in mammalian cells and the construction of expression vectors.

ASSOCIATE SCIENTIST #84079

Candidates should have a Ph.D./M.D. with background in experimental regulation of human or murine IgE production.

RESEARCH ASSOCIATE/RESEARCH ASSISTANT (2) #83158/83106

These positions assist in research directed towards the isolation and characterization of mammalian genes and their products. Requires M.S. or B.S. and 3+ years of experience in molecular biology. Experience in mRNA isolation, characterization and cDNA cloning desirable.

RESEARCH ASSOCIATES (2) #83010

Candidates will assist in maintenance and operation of amino acid analyzer & sequencer, purification and biochemical characterization of native & cloned human proteins.

Successful candidates should have B.S./M.S. in Biology or Biochemistry with a minimum of 2 years' experience in protein chemistry especially in the areas of high and low pressure liquid chromatography, protein assays, gel electrophoresis and isoelectric focusing.

This is an opportunity to join a dynamic company that encourages professional growth.

Send resume or apply in person to:

cetus®

An equal opportunity employer m/f/handicapped.

The European Molecular Biology Laboratory, a research institute situated in Heidelberg, West Germany, invites applicants for the following vacancies at the Laboratory's Outstation at the Deutsches Elektronen-synchrotron (DESY) site in Hamburg

APPLICATIONS PROGRAMMER

The successful candidate will help the scientists at the Outstation to design, develop and maintain data acquisition and application programmes for the synchrotron radiation experiments at the Outstation which include protein crystallography, time resolved scattering and X-ray spectroscopy (EXAFS) on biological systems.

He/she will also be expected to take part in the daily operations of the computers at the Outstation: VAX 11/750, PDP 11/45, PDP 11/24. Computer network access is used to maintain collaboration with other groups. Since a large number of projects are carried out by visiting workers, an ability to interact with people is indispensable.

An interest in applying computer technology to scientific problems is indispensable and previous programming experience in a scientific environment will be an asset. The ideal candidate would have at least 3 - 5 years experience using one or more high level languages (FORTRAN, PASCAL). Knowledge of assembler for PDP 11 or VAX is an advantage.

The net salary offered will be around DM 3900, - monthly. Certain allowances are payable in addition, depending on personal circumstances.
An initial contract of 3 years' duration, which can be renewed, will be offered.

Please write briefly for an application form quoting reference N°84/23 to:

CSIRO
AUSTRALIA
STATISTICIAN (STATISTICAL ECOLOGY)
$A25,342-$A37,274
DIVISION OF MATHEMATICS AND STATISTICS
CANBERRA ACT

CSIRO conducts scientific and technological research in laboratories located throughout Australia and employs about 7,500 staff, of whom some 2,900 are professional scientists. The Organization's research activities are grouped into five Institutes: Animal and Food Sciences, Biological Resources, Energy and Earth Resources, Industrial Technology and Physical Sciences. The CSIRO Division of Mathematics and Statistics is a member of the Institute of Physical Sciences.

The Division of Mathematics and Statistics has a staff of 97, including 75 professional scientists. The Division's Headquarters is at Canberra, and there are Regional Offices located at Melbourne, Sydney, Adelaide, Brisbane and Perth. Scientists of the Division provide advice on the statistical, mathematical and numerical aspects of research projects undertaken by scientists in other CSIRO Divisions, as well as conducting basic research in statistic and mathematics. The current statistical programs of the Division are:

- Regression analysis
- Design and analysis of experiments
- Multivariate analysis
- Analysis of remotely sensed data
- Geostatistics
- Signal analysis

The Canberra regional group of the Division has extensive and continuing collaboration with scientists from the CSIRO Institute of Biological Resources. The appointee will be involved in strengthening and widening these contracts, through the application of statistical methodology to biological and ecological research, and the development where appropriate of new techniques.

Applicants should have a proven record of research and collaboration in relevant areas of statistics. Expertise in the sampling of biological and ecological material, and the analysis of data thus collected, are particularly relevant. Familiarity with the role and practical application of modelling in these disciplines is also desirable.

Applicants should have a PhD degree or equivalent qualifications in a relevant branch of statistics, together with appropriate research and consulting experience.

The position is available for an indefinite period and Australian Government superannuation benefits are available.

APPLICATIONS: Stating full personal and professional details, the names of at least two referees and quoting reference No A3541, should be directed to:

The Chief
CSIRO Division of Mathematics and Statistics
GPO Box 1965
CANBERRA ACT 2601

United Medical & Dental Schools of Guy's & St. Thomas's Hospitals
NEW BLOOD LECTURESHIP
Department of Chemical Pathology

A molecular biologist with research experience is required in the Department of Chemical Pathology based at Guy's. The post offers the opportunity to work in association with a team involved in the development of malarial vaccines using recombinant DNA Technology. Applicants should submit an outline of research proposals relating to the investigation of human pathology.

Applicants wishing to visit the Department should contact Professor S Cohen (01-407 7600, ext 3365).

Appointment to this post will be for an initial period of three years. Applicants should not exceed 35 years of age and must not currently hold a permanent UK university appointment.

Salary in range £8,080 – £14,125 plus £1,186 London Allowance and Superannuation.

Application forms are obtainable from and should be returned to the Dean, Guy's Hospital Medical School, London Bridge, SE1 9RT not later than 21st June 1984.

(2172)A

INSTITUTE OF DERMATOLOGY (University of London)
Post-Doctoral Assistant

required for one year, to carry out research into analytical methods for peptide and phospholipid mediators of inflammation in human skin. An interest in modern instrumental techniques (HPLC, GCMS, FAB-MS) would be an advantage.

Salary on the Research Assistant Scale 1A.

Applications with the names of two referees to Dr A.I. Mallet, Institute of Dermatology, Homerton Grove, London E9 6BX, from whom further information can be obtained (Tel: 01-985 7061 ext 33).

THE UNIVERSITY OF LEEDS

DEPARTMENT OF BIOCHEMISTRY

LECTURER

Applications are invited for the above post available from 1 October 1984.

Salary on the academic scale for Lecturers (£7,190—£14,125) (under review) according to age, qualifications and experience.

Application forms and further particulars may be obtained from the Registrar, The University of Leeds LS2 9JT, quoting reference no 83/56D. Closing date for applications 21 June 1984.

The person appointed will participate in teaching biochemistry to science and medical students and will be expected to undertake research and should be appropriately qualified. (2162)A

Gene Manipulation

Team Leader

A vacancy has arisen in a large research-based pharmaceutical company situated in the South of England for a person to lead a team of scientists involved in the application of the latest gene manipulation technology to bring about the overproduction of medically important secondary metabolites from micro-organisms. The work of this group is supported by modern, well-equipped fermentation and scale-up facilities.

To qualify for this important post the successful candidate will be an accomplished scientist with a PhD and subsequent experience in the field of genetic engineering, who should also be conversant with the methodology and potential for yield enhancement of multi-genic pathways. This challenging position is ideal for a person who feels equipped to direct this work towards a successful commercial application.

In addition to a competitive salary, benefits include a non-contributory pension scheme, free life assurance and excellent sports and social facilities. Relocation expenses will be provided where appropriate.

Please write with full personal, career and salary details to the address below, quoting **ref: S3116/N** on the envelope. Your application will be forwarded directly to the client, unless marked for the attention of our Security Manager with a note of companies to which it should not be sent.

THE UNIVERSITY OF LEEDS

DEPARTMENT OF PLANT SCIENCES

POSTDOCTORAL RESEARCH FELLOW

Applications are invited for the above post for work on a project supported by ICI to study the growth and development of winter barley. The appointment will be made for a fixed period of up to four years, beginning as soon as possible.

Applicants should have, or shortly be expected to receive, a PhD in agricultural science or crop physiology. Experience in field studies of growth and development in cereals is desirable.

Initial salary up to £9,425 a year (under review) on the IA Scale for Research and Analogous Staff (£7,190-£11,615) (under review) according to age, qualifications and experience.

Informal enquiries may be made to Professor Elston (Tel (0532) 431751 ext 377).

Application forms and further particulars may be obtained from the Registrar, The University of Leeds LS2 9JT, quoting reference no 53/23D. Closing date for applications 25 June 1984. (2161)A

MOLECULAR BIOLOGIST - CANCER RESEARCH

The Upjohn Company, recognized as a world leader in pharmaceutical research, is seeking a Scientist with molecular biology training and experience to join its Cancer/Virus Research Department. Responsibilities will include the isolation, characterization, and utilization of cancer-related genes as part of the discovery process for new anticancer agents. Significant collaboration with departmental cell biologists in related departments is expected.

Candidates must have a Ph.D. (or equivalent degree) in biochemistry, microbiology, or related field with emphasis on the study of the molecular biology of cancer-related genes. Post-doctoral experience is desirable. Strong oral and written communication skills are required.

Upjohn offers a stimulating research environment, career potential, and peer recognition for scientific accomplishments. Publication of results and full interaction with the scientific community is expected. **For confidential consideration, send a current c.v., list of publications, names and addresses of references, and graduate transcripts (if appropriate) to: Gerald L. Potratz, Department 16278-G, The Upjohn Company, 7000 Portage Road, Kalamazoo, MI 49001.**

An Equal Employment Opportunity Employer M/F/H/V

British Museum (Natural History)

Plant Taxonomist

The British Museum (Natural History) is primarily an institution for taxonomic research and has world-wide collections of animals, insects, plants and minerals. There are 5 scientific departments which are supported by a comprehensive library and full technical services including electron microscope and computer facilities.

This opportunity is in the Department of Botany which has one of the largest collections of botanical specimens in the world, providing excellent opportunities for research on the relationships, biogeography and evolution of plants. The successful candidate will continue the project for a complete typification catalogue of Linnaean plant species, and bring it to a successful conclusion. Work will also include providing an on-going Departmental service for enquiries relating to types from older collections and contributing to Flora Mesoamericana, the main Departmental flowering plant research project.

Candidates must have a 1st of 2nd class honours degree in botany or a related subject and at least 3 years relevant postgraduate experience in plant taxonomy. A knowledge of the older literature and collections would be especially advantageous.

Appointment as Higher Scientific Officer £8,395-£10,810 (including £1250 Inner London Weighting) with starting salary according to qualifications and experience.

For further details and an application form (to be returned by 22 June 1984) write to Civil Service Commission, Alencon Link, Basingstoke, Hants, RG21 1JB, or telephone Basingstoke (0256) 68551 (answering service operates outside office hours).

Please quote ref SB/78/DK.

The Civil Service is an equal opportunity employer

UNIVERSITY OF ABERDEEN
DEPARTMENT OF MICROBIOLOGY

TEMPORARY LECTURESHIP

The Department of Microbiology invites applications for a Temporary Lectureship for one year from October 1984. The post arises from the award of the Nuffield Research Fellowship to Dr I R Booth, and the successful applicant will be expected to assist with teaching in microbial physiology, genetics and molecular biology. There will be the opportunity also to carry through a research programme.

Salary within the range £7,190 to £8,530 per annum, on lecturers salary scale (under review).

Further particulars and application forms from the Secretary, The University, Aberdeen, with whom applications (2 copies) should be lodged by 15 June, 1984. (2139)A

UNIVERSITY OF LEICESTER
Leicester Biocentre

POSTDOCTORAL RESEARCH ASSOCIATE
Yeast Molecular Biology

Applications are invited for a postdoctoral research position, funded by a major UK Food and Drink company, to undertake research aimed at the improvement of existing yeast strains for commercial applications.

The project will involve the use of genetical, biochemical and recombinant DNA methods and Applicants should hold a PhD in a relevant subject. The contract is for a period of 3 years and appointment will be made within the Grade 1A salary scale (ie £7,190 — £11,615).

Applications, with full curriculum vitae should be sent to the Secretary, Leicester Biocentre, University of Leicester, Medical Sciences Building, Leicester LE1 7RH. (2105)A

DEPARTMENT OF BIOLOGY

Postgraduate Research Training

Three opportunities for research training, leading to MPhil/PhD (CNAA), will exist in the department from 1 September 1984. The following project areas are available:

Photoperiodism and Reproduction; Feedback control mechanisms on ion absorption and transport in higher plants; Allosteric models and haemoglobin; Production and characterisation of monoclonal antibodies for use in a diagnostic kit to detect demyelination; Biochemical mechanisms of resistance to aminoglycosides in clinically isolated bacteria; Laboratory selection for pesticide resistance in predatory mites; Glycoprotein metabolism in nerve terminals; *In vitro* construction of Tn5-derived transposons carrying novel selective markers and transactivated oriT regions; Physiological and biochemical indicators of alcohol consumption in support of clinical therapies; Numerical aspects of species diversity in insects.

Further details of the projects and of research in the Department available from the Postgraduate Tutor. Two of the posts are Researcher A appointments (£4,947 pa under review) associated with some teaching duties in physiology and biochemistry respectively.

Applicants should possess a good honours degree in an appropriate subject. They should provide a curriculum vitae including full details of any experience relevant to the project they nominate, and the names of two academic referees. Applications should be sent as soon as possible to:

The Postgraduate Tutor, Department of Biology, Oxford Polytechnic.

DEPARTMENT OF GEOLOGY AND PHYSICAL SCIENCES

Temporary Lecturer II/ Senior Lecturer in Geology Ref: GPS/ 31

Applications are invited for a one-year, full time temporary post in the Department from suitably qualified candidates. The post will be available from 1 September 1984 to 31 August 1985.

The successful candidate will in part, be resonsible for the teaching of Petrology and Mineralogy as part of the Polytechnic's modular degree course. Petrology and Mineralogy are taught within the named degree in Earth Sciences and the Geology single field honours degree.

Teaching responsibilities will be in at least two of the following areas: Metamorphic Petrology; Igneous Petrology with special reference to Plutonic Rocks; Introductory Mineralogy and Petrology. In addition the successful candidate will be required to supervise undergraduate field trips, may be required to teach geological map work and will be encouraged to participate in research.

Salary Scale
LII £7,215 — £11,568

Salary Scale
SL £10,683 — £13,443
under review)

Further details and application forms are available from the Staffing Department, ext 363.

The closing date for these posts is 15 June 1984. (2193)A

THE UNIVERSITY OF IOWA
DEPARTMENT OF CHEMISTRY

POSTDOCTOROAL POSITIONS (2) — ENZYME MECHANISMS

Two postdoctoral positions are available beginning July 1, 1984, for persons with research experience and interests in physical biochemistry and/or enzyme biochemistry. One position is to study the mechanisms of the lipolytic enzymes cholesteryl esterase and lipoprotein lipase. The second position is to study the mechanism of acetylcholinesterase (see J Amer Chem Soc (1984) 106, 1883-1884). Both positions involve the design and synthesis of substrates for the studied enzymes and the states by a range of reaction kinetics probes, including: solvent and substrate isotope effects, temperature and pH effects, effects of organic cosolvents, nucleophilic trapping of intermediates. The lipolytic enzume and study of enzyme activation by artificial membranes. Experience in enzyme kinetics and/or purification is necessary. Some experience in synthetic organic chemistry is desirable but is not required. Please send résumé and arrange for two letters of recommendation to be sent to:

Dr Dan Quinn, Department of Chemistry, The University of Iowa, Iowa City, Iowa 52242. Phone: 319-353-6398

The University of Iowa is an Affirmative Action/Equal Opportunity Employer. (NW561)A

ASSISTANT PROFESSOR of Immunology and Infectious Diseases. (Parasitology). The Johns Hopkins University invites applications for this position from candidates who have strong interest in the parasitic diseases. Curriculum vitae, description of research goals and interests, and the names, addresses, and telephone numbers of three referees should be submitted to: The Chairman, Department of Immunology and Infectious Diseases, The Johns Hopkins University School of Hygiene and Public Health, 615 North Wolfe Street, Baltimore, Md 21205. The Johns Hopkins University is an Equal Opportunity Employer. (NW566)A

(NW572)A

AGRICULTURAL AND FOOD RESEARCH COUNCIL

FOOD RESEARCH INSTITUTE (Chemistry and Biochemistry Division)

PHYSICIST/BIOPHYSICIST BIOCHEMIST/CHEMIST

As a result of additional funding by the Ministry of Agriculture, Fisheries and Food, the following posts are available in the Chemistry and Biochemistry Division. The posts are aimed at expanding the commitment in research into Biopolymers already in the Division. There is substantial existing expertise in the isolation and characterisation of proteins and polysaccharides. There is also a major emphasis on the use of modern physical methods to study molecular behaviour. The methods available on site include: light-scattering, X-ray diffraction, low-angle X-ray scattering, electric birefringence, flow birefringence, multinuclear NMR spectroscopy, high-power NMR spectroscopy (including MAS facility), differential scanning calorimetry, dilatometry and electron microscopy. Links with specialist University departments are established to extend further the range of available techniques.

The posts are concentrated in two areas of research.

A. THE FUNCTIONAL PROPERTIES OF CEREAL PROTEINS (Posts 84/NP/15, 84/NP/16 and 84/NP/17):

The aim of the research is to determine the structural factors that control the performance of cereal proteins, especially gluten, in food, e.g., in baked products. The programme will involve isolation and characterisation of cereal proteins, determination — by physical and spectroscopic methods — of their structures, including structural changes as a result of denaturation, and the study of physicochemical and rheological behaviour of protein solutions and gels related to changes of molecular structure.

B. THE PROPERTIES OF STARCHES (Posts 84/NP/4, 84/NP/5 and 84/NP/6):

The aim is to identify the molecular processes that determine the stability of starch and startch-protein gels. The programme will involve the study of (i) the solution behaviour of well-characterised starch polysaccharides, using light-scattering and viscometry; ((ii) the molecular association in concentrated systems, using X-ray diffraction, dilatometry and differential scanning calorimetry; and (iii) related studies in changes in mechanical behaviour.

Qualifications: Details of the posts are as follows:

PROTEIN BIOCHEMIST, Higher Scientific Officer (84/NP/15)
A first or upper second-class honours degree in Biochemistry and at least two years' postgraduate experience, preferably a Ph.D., in Protein Biochemistry or Enzymology. Expertise in the characterisation of proteins is essential and ability to interact with biophysicists in a multidisciplinary team, desirable.

BIOCHEMIST, Scientific Officer (84/NP/16)
A degree in Chemistry or Biochemistry. Aptitude for careful manipulation of sensitive biopolymers is essential.

PHYSICAL CHEMIST/SPECTROSCOPIST, Scientific Officer (84/NP/17)
A degree in Physical Chemistry. Experience with the use of physical or spectroscopic methods in biological systems is desirable.

BIOPHYSICIST/PHYSICAL BIOCHEMIST, Higher Scientific Officer (84/NP/4)
A first of upper second-class honours degree in Physics, Physical Chemistry or a related subject and at least two years' postgraduate experience, preferably a Ph.D., in the molecular behaviour of proteins or polysaccharides. Experience with using physical techniques to study complex biopolymeric systems is essential.

PHYSICAL CHEMIST/PHYSICIST, Scientific Officer (84/NP/5)
A degree in Physical Chemistry or Physics. Interest in the application of physical methods to the study of biological systems is essential.

PHYSICIST/PHYSICAL CHEMIST, Scientific Officer (84/NP/6)
A degree in Physics of Physical Chemistry. Experience with the study of the bulk rheology of systems is desirable.

Salary scales: Higher Scientific Officer £7,149-£9,561, Scientific Officer £5,682-£7,765 (under review).

Non-contributory superannuation scheme.

The Agricultural and Food Research Council is an Equal Opportunities Employer.

Further information and application forms from the Secretary, Food Research Institute, Colney Lane, Norwich NR4 7UA, quoting the appropriate reference number. Closing date: 15th June, 1984. (2209)A

ROYAL DUTCH/SHELL GROUP OF COMPANIES

Production/ Development Geologists

International career opportunities

Production Geologists are responsible for all geological matters relating to the appraisal and development of oil and gas discoveries and work in close cooperation with other branches of petroleum engineering. They take a leading part in field appraisal and the resultant pre-development plans, siting of development wells and construction of detailed geological models for use by the Reservoir Engineers.

Minimum requirements are an upper second class degree in geology, and at least four years relevant experience. An additional higher degree will be regarded as evidence that candidates are fully equipped to take advantage of longer term career prospects. Applicants must be familiar with the principles of petroleum geology, and should have an extensive knowledge of well log correlation, subsurface mapping techniques, seismic interpretation and geological analysis of clastic and/or carbonate reservoirs. A basic knowledge of general petroleum engineering and data processing would be an advantage.

We offer a career with excellent prospects for development and promotion. Starting salaries will be commensurate with background and experience. Applicants must be prepared to work overseas for a large part of their career. Benefits will include attractive family accommodation, primary schooling or assistance with boarding school fees, free annual leave passages, good recreation and medical facilities, and an excellent pension scheme.

Please write for an application form to:

(2219)A

Shell International Petroleum Company Limited, Recruitment Division (N1), PNEL/22, Shell Centre, London SE1 7NA.

THE UNIVERSITY OF GLASGOW

DEPARTMENT OF BIOCHEMISTRY

POSTGRADUATE RESEARCH ASSISTANT

A position is available, under a grant from the Muscular Dystrophy Group of Great Britain, for a research assistant to pursue recombinant DNA studies in relation to Duchenne Muscular Dystrophy commencing 1st October, 1984.

Applicants should have, or expect to gain, a first or upper second class honours degree in Molecular Biology, Genetics, Biochemistry or other relevant biological science; and the appointee will register for a PhD. The work involves construction of genomic DNA libraries and identification of X-chromosome specific cDNA clones.

Letters of application, including curriculum vitae and the names of two referees, should be addressed to: Dr D P Leader, Department of Biochemistry, University of Glasgow, Glasgow G12 8QQ. (2168)A

FACULTY POSITION

MOLECULAR GENETICIST

The Division of Clinical Immunology and Rheumatology is inviting applications for a tenure-track position at the assistant/associate professor level. A strong commitment to research excellence will be the main criterion of selection. Training in molecular biology is required and research interests in the areas of immunology or mechanisms of inflammation preferred. Candidates must have demonstrated research ability and will be expected to establish a strong independent research program. preference will be given to candidates holding an MD degree. opportunities for participating in graduate programs of Basic Science Departments are available. Curriculum vitae, statement of research goals and interests and names of three referees should be sent by August 1, 1984, to: John E Volanakis, MD, Molecular Geneticist Search Committee, Division of Clinical Immunology and Rheumatology, University of Alabama in Birmingham, Birmingham, Alabama 35292. An Equal Opportunity/Affirmative Action Employer. (NW568)A

UNIVERSITY OF STRATHCLYDE

"New Blood" Lectureship
In Food Science Division
Department of Bio-science and Bio-technology

Applications are invited from candidates under 35 years of age for a lectureship in food science. Preference will be given to candidates with post-doctoral research experience in food related topics. Experience in one or more of the following areas will be an advantage:-

Biopolymers, rheology, food preservation, food microbiology, food processing and control systems.

Salary will be on a lecturer scale (£7,190 – £14,125 p.a.) USS Benefit.

Further particulars and application forms (quote ref 30/84) are available from Staff Office, McCance Building, 16 Richmond Street, Glasgow G1 1XQ.

Closing date for applications: 29 June 1984. (2227)A

RESEARCH ASSOCIATE POSITION AVAILABLE

Research program is in the area of molecular basis of calcium action, especially the mechanism of action of the calmodulin family of proteins. Background in Molecular Biology or Biochemistry preferred, but motivation and ability to interact with a multidisciplinary group more important. Send curriculum vitae and names of two references to D Martin Watterson, Department of Pharmacology and Howard Hughes Medical Institute, 723 Light Hall, Vanderbilt University, Nashville, TN 37232. (NW573)A

Neurobiologist

Postdoctoral position available to study chemosensory transduction in vertebrate taste cells. Research involves intracellular recording and dye-filling, patch-clamping, structure/function correlations with electron microscopist. Experience in electrophysiology, particularly intracellular microelectrodes desirable.

Contact Dr S. Roper, Rocky Mt. Taste and Smell Center, B-111, University of Colorado Medical School, 4200 E. 9th Ave., Denver, CO 80262. Affirmative action/Equal opportunity employer. (NW567)A

CENTRE FOR REPRODUCTIVE BIOLOGY,
UNIVERSITY OF EDINBURGH

GYNAECOLOGIST

Applications are invited from gynaecologists for a clinical post established by the Medical Research Council to promote the research and development of new approaches to contraception and menstrual induction, and the treatment of reproductive disorders. A Honorary Clinical Contract will be arranged with the local Health Authority for the successful candidate. The terms of this contract are negotiable, but will be designed to provide access to patients, both for research and for the development of the candidate's clinical career. Outstanding opportunities exist for clinical research in the Simpson Memorial Maternity Pavilion, adjacent to the Centre for Reproductive Biology, and for collaboration with the Scientific Staff of the Centre. Applicants should have their MRCOG and have undertaken some research.

The appointment will be made on the MRC Clinical Scales, at the equivalent of Senior Registrar or Consultant Grade.

Applications, including a full curriculum vitae, list of publications and the names of three referees should be sent by 25th June to Dr D W Lincoln, Director, MRC Reproductive Biology Unit, Centre for Reproductive Biology, 37 Chalmers Street, Edinburgh EH3 9EW (telephone number 031 229 2575).

Clinical Research

Antibiotics
Excellent salary + car

Roussel Laboratories is part of the world's largest and most innovative ethical pharmaceutical company.

The medical department, based at our Wembley Park head office (moving later this year to Denham, Bucks), is seeking a Senior Clinical Research Scientist to join its team of medical advisers, scientists and statisticians. This is a unique opportunity for someone to develop their skills working on post marketed antibiotics and projects, and to build up contacts with opinion leaders in the medical field by organising clinical trials and symposia.

Probably in your 30s with a BSc, MSc or PhD, preferably in microbiology, you will ideally have at least five years' experience in a similar role with a pharmaceutical company, working on antibiotics. You must have a strong interest in post marketed products and possess the necessary resourcefulness, drive, and contacts in the industry and the medical field to enable you to handle projects alone.

We provide a first-class range of benefits including free family BUPA after a year's service, free restaurant, free life and personal accident insurance, contributory pension, and generous relocation assistance where appropriate.

Please send a detailed cv, including current salary, or ring or write for an application form to Mrs Elizabeth Bedford, Roussel Laboratories Limited, Roussel House, Wembley Park, Middlesex HA9 0NF. Telephone: 01-903 1454.

ROUSSEL

(2199)A

THE MIDDLESEX HOSPITAL MEDICAL SCHOOL

(University of London)
London W1P 6DB

Applications are invited for the post of

LECTURER IN ANATOMY

Applicants should have experience in gross anatomy teaching and the successful candidate will be encouraged to help in the development of the gross anatomy teaching programme. Candidates should also be committed to research and will be encouraged to develop their own research programme. Current research interests in the Department range over Developmental Biology, Hominid Palaeontology, Comparative Anatomy, Cell Membranes and the Ultrastructure of Peripheral Nerves. Applications are particularly invited from candidates whose research interests are allied to Hominid Palaeontology and Evolutionary Biology.

Salary according to age, qualifications and experience within the range £8,376 — £15,312 inclusive of London Allowance. Further details may be obtained from Professor Bernard Wood (Tel 01-636 8333 ext 7179).

Applications including cv and names and addresses of three referees to Professor B A Wood, Department of Anatomy and Biology at the above address as soon as possible.

(2184)A

UNIVERSITY OF DUNDEE

CHAIR OF BIOCHEMISTRY

Applications are invited for the Chair of Biochemistry which will fall vacant on 1 October 1984 as a result of the resignation of Professor P B Garland to take up a senior research post in industry.

Further particulars are available from The Secretary, The University, Dundee DD1 4HN with whom applications (10 copies, or if posted overseas one copy) containing full career details, a summary of research interests, and the names of three referees should be lodged as soon as possible. Please quote reference EST/18/84. It is intended that short-listed candidates should be interviewed in Dundee before the end of September, 1984 (J). (2189)A

CHAIRPERSON

DEPARTMENT OF ANATOMY

Applications and nominations are invited for the position of Professor and Chairperson, Department of Anatomy, University of South Carolina School of medicine, Columbia, South Carolina. Candidates should have a record of scholarly activity, including excellence in teaching, preferably in gross anatomy, active research interest and administrative and leadership skills. Applications and nominations will be accepted until June 30, 1984. Please submit to: O'Neill Barrett, Jr., MD, Chairman, Anatomy Search Committee, USC School of Medicine, c/o Richard Memorial Hospital, ACC No 2, Columbia, SC 29203. An Equal Opportunity/Affirmative Action Employer. (NW571)A

Post Doctoral, Research Scientist

Department of Haematology and Oncology

Royal Children's Hospital Melbourne, Australia

An opportunity exists to undertake a leading research role in the fields of childhood leukaemia and childhood solid tumours for a scientist with experience in this field. The research laboratory, part of the department of Clinical Haematology and Oncology undertakes the care of more than 400 children with a variety of leukaemias and solid tumours and is the paediatric centre for bone marrow transplantation and autologous bone marrow rescue. Development and research are well established in the department and a list of research activities and publications will be forwarded on request. The Royal Children's Hospital is a major Paediatric centre in Australia and very good scientific support facilities are available in virtually all disciplines including immunology and recombinant DNA technology. Joint research projects with the Walter and Eliza Hall Institute and the Ludwig Cancer Research Institute are well established. Technical help will be available and there is scope for training of doctoral fellows.

The successful candidate will be funded at the appropriate N.H. and M.R.C. scale for seniority and experience (range $A20,164.00-$A30,737.00). Funds are available for a three year appointment, however transport and removal expenses cannot be provided.

Written applications describing the candidates area of interest, expertise, the proposed research programme for the three years, a curriculum vitae and the names and addresses of at least two referees, should be addressed to Dr. H. Ekert, Department of Haematology and Oncology.

Applications close Friday, 20th July, 1984.

Dr. Barry R. Catchlove,
Chief Executive.

Royal Children's Hospital

Flemington Road, Parkville 3052, Victoria, Australia.

CSIRO
AUSTRALIA
RESEARCH FELLOW
$A25,342-$A31,270
DIVISION OF SOILS
CANBERRA ACT

CSIRO conducts scientific and technological research in laboratories located throughout Australia and employs about 7,500 staff, of whom some 2,900 are professional scientists. The Organization's research activities are grouped into five institutes: Animal and Food Sciences, Biological Resources, Energy and Earth Resources, Industrial Technology and Physical Sciences. The CSIRO Division of Soils is a member of the Institute of Biological Resources.

GENERAL: The CSIRO Division of Soils studies the physics, chemistry and biology of soils and other porous media, together with the integrative disciplines of pedology and geomorphology. It also seeks to establish principles for the application of soil science to agriculture, forestry, hydrology, engineering and conservation. The Division has laboratories in Adelaide, Brisbane, Canberra and Townsville.

Micromorphological studies are used in the interpretation of soil genesis and in the explanation of many soil properties and forms of behaviour. Facilities for micromorphological studies at the Canberra Laboratories include comprehensive thin-sectioning equipment, a range of binocular and polarizing microscopes, computerised quantitative image-analysis systems, a rainfall tower for the simulation of field conditions and a wide range of anciliary facilities in the sub-disciplines of soil physics and chemistry. Access to a scanning electron microscope and electron microprobe is also available within the Division.

DUTIES: The appointee will undertake research on relationships between micromorphology and the physical and mechanical properties of soils. In particular, the studies will focus on the relationship between soil structure and hydraulic conductivity, compaction and shear in clay soils, using dyes, direct shear-box tests and quantitative image-analysis. There will also be opportunities to assist with general micromorphological studies of soil A horizon properties and soil genesis.

QUALIFICATIONS: A PhD degree or equivalent qualifications in soil science, physical geography, or geology with basic skills in microscopy and preferably some experience in soil physics and pedology.

LOCATION: The appointee will be based in Canberra, ACT.

TENURE: A term of 5 years. Australian Government superannuation benefits available.

APPLICATIONS: Stating full personal and professional details, the names of at least two referees and quoting reference No A3269, should be directed to:

The Chief
CSIRO Division of Soils
GPO Box 639
CANBERRA ACT 2601
AUSTRALIA

By June 29, 1984.

CSIRO IS AN EQUAL OPPORTUNITY EMPLOYER

(W1019)A

The International Livestock Centre for Africa (ILCA) has a vacancy for an

Agricultural Economist

in ILCA's Humid Zone Programme based in Ibadan, Nigeria, where the research focuses on small ruminants. The appointee will be a member of a multi-disciplinary team and will carry out field surveys and analyse and evaluate existing production systems and proposed changes in these.

The successful candidate will have a PhD in agricultural economics or an MSc plus several years experience working on smallholder farming systems in developing countries.

For a person recruited internationally the appointment will be initially for two years, with an attractive tax-free salary payable in US$ outside Nigeria. In addition to salary various allowances are payable.

Applicants should send a curriculum vitae and the names of three referees by June 30, 1984 to:

The Director General
ILCA, P.O. Box 5689
Addis Ababa, Ethiopia

Addis Ababa, 26 April 1984. (W1018)A

Population Biologist

The Sea Mammal Research Unit is seeking a Biologist or Mathematician to join a small team developing and refining techniques for estimating the size and status of seal and whale populations. The research will involve both mathematical and statistical modelling and fieldwork, the latter often under unpleasant conditions. Experience of the application of a variety of mathematical techniques to biological problems, work with large mammals in the field, and handling of small boats would be an advantage.

Appointment will be at the Scientific Officer grade (£5,682 — £7,765 pa) or Higher Scientific Officer grade (£7,149 — £9,561 pa), depending on qualifications and experience.

For further details and an application form write to the Sea Mammal Research Unit, c/o British Antarctic Survey, High Cross, Madingley Road, Cambridge CB3 0ET quoting post no SM/10.

Closing date for applications: 21st June 1984. (2220)A

NATURAL ENVIRONMENT RESEARCH COUNCIL

UNIVERSITÄT ULM

An der Fakultät für Theoretische Medizin ist die

C4 Professur für Virologie

(Nachfolge Prof Dr A.K. Kleinschmidt) zu besetzen. Mit der Professur ist die Leitung der Abteilung Virologie (Mikrobiologie I) verbunden. Der Stelleninhaber hat das Fach Virologie in Forschung und Lehre sowie in der mittelbaren Krankenversorgung zu vertreten.

Wissenschaftlich sollte er in molekularbiologischer Forschung ausgewiesen sein; Beteiligung an einem zellbiologisch orientierten SFB sowie an der Lehre in Biologie für Fortgeschrittene wird erwartet.

Bewerber werden gebeten, die üblichen Unterlagen bis zum 2. Juli 1984 an den Dekan der Fakultät für Theoretische Medizin der Universität Ulm, Postfach 4066, D-7900 Ulm (Donau), zu senden. (W1017)A

M.R.C. CLINICAL RESEARCH CENTRE
(NORTHWICK PARK HOSPITAL)
WATFORD ROAD, HARROW
MIDDX HA1 3UJ

POSTDOCTORAL FELLOW IN MOLECULAR IMMUNOLOGY

Applications are invited from science graduates for a 3-year postdoctoral position in the transplantation biology section to work with Dr A. Mellor on a project to clone and characterise human and mouse genes which encode minor histocompatibility antigens.

Candidates should have previous experience with recombinant DNA techniques. A knowledge of immunological techniques would be helpful but is not essential.

Salary scales are related to those for University Non-Clinical Academic Staff and salary on appointment will depend on age and experience. For an application form write to Miss J. Cottam, Personnel Section quoting reference 129/ 1/ 4517. Closing date for applications, 22nd June 1984. (2181)A

THE UNIVERSITY
OF SHEFFIELD
DEPARTMENT OF
PHYSICS

1 RESEARCH ASSOCIATE
and
2 PHYSICIST
PROGRAMMER IN HIGHER
ENERGY PHYSICS

Applications are invited from men and women for the above SERC funded posts, tenable for two years from 1 October 1984, with the possibility of a third year.

Post 1 concerns a photoproduction experiment using a tagged photon beam and Omega detector at CERN.

Post 2 involves work in two areas: the on-line system for the ALEPH experiment associated with the LEP project at CERN and off-line analysis using the University's Workstation.

A good honours degree in physics is required together with postgraduate experience in the experimental techniques of particle physics. Initial salary £7,190 — £9,425 a year on range IA according to age, qualifications and experience.

Applications, including curriculum vitae and the names of two referees, should be sent to Professor W Galbraith/Dr F Combley, Department of Physics, The University, Sheffield S10 2TN, by 15 June 1984. Quote ref: R95/. (2224)A

RECENT PhD BIOCHEMISTRY — Protein Chemistry/Enzymology. Experienced with many laboratory techniques such as immunochemistry, isoelectric focusing, etc., and instruments such as CD, NMR, fluorometry, etc. Seeks position as postdoctoral/research associate/teaching. Available immediately. Reply to Box 42, Nature, 15 East 26th Street, New York, New York 100100, USA. (NW570)A

UNIVERSITY
OF ST ANDREWS

ANATOMY & EXPERIMENTAL
PATHOLOGY

RESEARCH ASSISTANT

Applications are invited from recent graduates for a post of Research Assistant required to assist in the production of monoclonal antibodies against malignant melanoma cells. Experience in membrane biochemistry, cell culture or monoclonal antibody production would be advantageous. The appointment is funded by a grant from the NFCR and will be for one year in the first instance with the prospect of renewal.

Starting salary £6,310 per annum (under review) plus USS.

Applications with full curriculum vitae and the names of two academic referees should be sent as soon as possible to Dr Clive W Evans, Department of Anatomy and Experimental Pathology, University of St Andrews, St Andrews, Fife KY16 9TS, from whom further particulars may be obtained. (2214)A

Yeast Microbiologist

Top salary + car

Burton upon Trent, Staffordshire

Bass, Europe's largest brewing group, wish to appoint an experienced specialist who will be responsible to the Quality Control Director. He/she will provide a microbiological service to all Bass breweries and supervise activities of the Group QC laboratory.

Duties will include supervision of the Bass Yeast Quality Assurance Policy, advice to breweries in respect of yeast propagation systems and yeast husbandry. Also assessment of new/improved microbiological techniques to meet specific QC needs.

Applicants with specialised knowledge of brewing yeasts and propagation systems are required to have a minimum qualification of B.Sc. Hons. 2(1) in Microbiology or a related discipline and have at least 5 years post graduate experience in the brewing/fermentation industries. Experience and enthusiasm for microbiological trouble shooting would be advantageous.

Salary will be commensurate with age and experience. The Company operates a generous life assurance and pension scheme and provides comprehensive recreational facilities.

Detailed application including c.v. and names of two referees, should be sent as soon as possible to:-

HQ Staff Personnel Manager, Bass Public Limited Company, 137 High Street, Burton upon Trent DE14 1JZ

Bass

LECTURERS IN ZOOLOGY

Applications are invited for two Lectureships in the Department of Zoology. Persons appointed will be required to contribute to general undergraduate courses in biology and zoology and to teach and conduct research in specialist aspects of the subject. One post is in terrestrial vertebrate ecology and population biology, the other in experimental zoology and comparative physiology of invertebrates or lower chordates.

Salary: Lecturer: NZ$21,660-$25,684 per annum, plus NZ$8.00 per week cost-of-living allowance.

Further information, including method of application, is available from the Secretary General, Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF, or from the Registrar, University of Otago, PO Box 56, Dunedin, New Zealand.

Applications close on 31 July 1984. (2204)A

UNIVERSITY OF ESSEX
DEPARTMENT OF CHEMISTRY

LECTURESHIP IN AEROSOL SCIENCE

A special grant by the UGC enables the University to develop significantly its work in the field of aerosol science and an appointment has been made to a Readership in this field.

Applications are now invited for a second post, that of Lecturer (salary scale £7,190 — £14,125), for a period of five years, with a possibility of renewal, tenable from 1st October 1984 or as soon as possible thereafter. The main duties of the post will be to undertake research and postgraduate teaching in aerosol science and to contribute to undergraduate teaching in this and related areas. Applications are invited from candidates with experience in aerosol science or with an appropriate background and wishing to develop their interests in aerosol science research.

Applications (ten copies), including a curriculum vitae and the names and addresses of two referees, should reach the Registrar (AG/176/N), University of Essex, Wivenhoe Park, Colchester CO4 3SQ, from whom further particulars may be obtained, by 21 June 1984. (2156)A

MOLECULAR BIOLOGIST position for research scientist/assistant professor of medicine to participate in ongoing projects and develop independent research using recombinant DNA technology. PhD in biochemistry, molecular biology, or related area required. Postdoctoral experience preferred. Send resumé, description of research interests, and three letters of reference by 15 June 1984 to: Dr Ron MacQuarrie, Department of Chemistry, University of Missouri-Kansas City, Kansas City, Missouri 64110. The University of Missouri is an Equal Opportunity/Affirmative Action Employer. (NW574)A

UNIVERSITY OF ZIMBABWE

Applications are invited for the following posts:

LECTURESHIP/ SENIOR LECTURESHIP/ ASSOCIATE PROFESSORSHIP:

DEPARTMENT OF GEOLOGY

This post requires someone with an expert knowledge of metamorphic petrology, preferably with a PhD. An interest in economic geology would be an advantage, while experience in Electron-microprobe and/or analytical techniques are also desirable. The successful candidate will be required to teach metamorphic petrology in the undergraduate BSc General courses; to teach, and supervise field projects, at BSc Sepcial Honours level; and to supervise higher degree students as necessary. He/She may be required to teach introductory courses in the BSc General degree, and service in other Faculties.

LECTURESHIP/ SENIOR LECTURESHIP/ ASSOCIATE PROFESSORSHIP:

DEPARTMENT OF BIOCHEMISTRY (FOOD CHEMISTRY/ BIOCHEMISTRY POST)

Applicants should have a postgraduate degree, preferably a PhD in Food Science from a recognised university with teaching and research experience in a University Food Science programme The successful candidate will be expected to undertake teaching and research in Food Biochemistry and Food Analysis and to supervise MSc Projects in liaison with industry.

Salary scales: Lecturer: Z$10,440 x 456-$16,368 x 504-$17,376. Senior Lecturer: Z$17,880 x 504-$20,400. Associate Professorship: Z$18,384 x 504-$20,904.

Appointment on above scales according to qualifications and experience.

Conditions of service: Both permanent and short-term contracts are offered. Persons who are not Zimbabwean citizens may be appointed only on a short-term contract basis with an intial contract period of two years. Short-term contracts may, in exceptional cases, be extended.

Application forms and further particulars on the above posts can be obtained from the Director, Appointments and Personel, University of Zimbabwe, PO Box MP 167, Mount Pleasant, Harare, Zimbabwe, or from the Secretary General, Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF.

Closing date for receipt of completed application forms is 13 July 1984. (2208)A

POSTDOCTORAL ASSOCIATE position immediately available for recent PhD biochemist to participate in research program on control mechanisms for cell growth. Focus on the molecular signals controlling transcription and translation of cardiac proteins. Expertise in nucleic acid and protein chemistry essential. Experience in purification and identification of peptides and cell free translation of mRNA important. This is a collaborative program between the Department of Surgery of Yale Medical School and the Department of Biology, Yale University. Salary will be above NIH guidelines. Send curriculum vitae to: Graeme L Hammond, MD, Department of Surgery, Yale Medical School, PO Box 3333, New Haven, Conn 06510. Equal Opportunity Employer. (NW562)A

WORKSHOP

WORKSHOP ON ABNORMAL CELLS, NEW PRODUCTS, AND RISK
Co-sponsored by:
FDA, NCI, NIAID, NHLBI, and CDC
will be held on July 30-31, 1984
at the NIH in Bethesda, MD, USA

The meeting has been organized to review issues and data relating to the use of abnormal cells in the production of drugs and biologics. Particular attention will be focused on three areas: (1) residual cellular DNA in products; (2) viruses endogenous to the cell substrate; and (3) residual cellular proteins in products. Discussions will follow the presentation of data, and there will be an attempt to develop consensus in each of the three areas during the afternoon of the second day. The Public Health Service Agencies co-sponsering this workshop believe it will assist them in making decisions on the support of research, the regulation of products, and the use of products derived from abnormal mammalian cells. The meeting is open to the public; however, individuals planning to attend should send their name and address to: Mary Ann Tourault, Food and Drug Administration, 8800 Rockville Pike, Bethesda, MD 20205 so that additional information can be sent in advance of the meeting. (NW575)V

STUDENTSHIPS

UNIVERSITY OF STRATHCLYDE
DEPARTMENT OF PHYSICS

DEVELOPMENT OF NOVEL LASERS AND INFRA-RED REMOTE SENSING

Applications are invited for three CASE Research studentships in Experimental Laser Physics. The projects will be concerned with the development of tunable solid state lasers for the visible and near infra-red regions and with the generation of ultra-short pulses, (co-operating body Barr and Stroud Ltd), development of tunable waveguide CO_2 lasers (co-operating body Edinburgh Instruments Ltd.), and with infra-red spectroscopy for remote sensing (co-operating body National Physical Laboratory).

Potential candidates, who should have or expect to obtain a good Honours Degree in Physics, Chemistry or Electronics can obtain further information from
Professor B. Henderson, Department of Physics, University of Strathclyde, John Anderson Building, 107 Rottenrow, Glasgow G4 0NG (2218)F

Prevention and Detection of Cancer

6TH INTERNATIONAL SYMPOSIUM

Vienna, Austria

26 to 29 November, 1984

SCIENTIFIC PROGRAM*

26 November, 1984

HOST FACTORS
- Familial host factors
- Genetic predisposition
- Aging and cancer
- Hormones and cancer
- Immune surveillance
- Psychosocial profiles and lifestyle

TOBACCO
- Behavioral changes
- Lung cancer
- Oral cancer
- Other cancer
- Ambient tobacco smoke
- Combination carcinogenic effect

MOLECULAR BIOLOGY I
- Oncogenes
- Biochemical mechanisms of carcinogenesis
- Virus and cancer

TOBACCO IMPLEMENTATION WORKSHOP
- Education
- Low tar cigarette
- Advertising (mass media)
- Taxation policy
- Agricultural alternatives
- Legislation

27 November, 1984

CLINICAL DETECTION
- Identification and surveillance of individuals at high risk exposure
- Identification of genetically susceptible individuals
- Biochemical markers of tumor diathesis and early cancer
- Cellular markers of tumor diathesis and early cancer
- Mass screening
- Automation in screening projects: use of high tech

IMMUNOPATHOLOGY
- Cell membrane structure and function
- Antibodies in diagnosis and surveillance of cancer patients
- Assessment of host immune response to tumors
- T cell subsets
- Tumor cell macrophage interactions
- Human hybridomas

MOLECULAR BIOLOGY II
- Chromosomes and cancer
- Differentiation and cancer
- Cytoskeletal alterations
- Cell kinetics and cancer

STRATEGIES FOR PREVENTION IMPLEMENTATION WORKSHOP
- Government organization
- Voluntary and community organization
- Medical and professional organization
- Individual habits and education

28 November, 1984

PRECURSORS
- Prenatal and childhood exposure to carcinogenic factors
- Genetic predisposition
- Clues from experimental carcinogenesis for prevention
- Biology of precursor lesions
- Identification of benign and potentially malignant lesions
- Specificity of environmental factors on precursor lesions

NUTRITION
- Vitamins
- Trace metals
- Protein and calories
- Fat
- Fiber
- Food additives and contaminants
- Childhood nutrition
- Epidemiology: micronutrients

VIROLOGY
- HTLV, leukemia and immunology
- HSV II and cervical cancer
- Papilloma virus and cervix
- EBV and human malignancies
- Hepatitis B and liver cancer

STRATEGIES FOR DETECTION IMPLEMENTATION WORKSHOP
- Government organization
- Voluntary and Community organization
- Medical: modalities to accomplish detection; cost benefit
- Individual: self-examination, self-questionnaire, motivation
- Priorities for training

29 November, 1984

TUMOR MARKERS
- Biologic basis
- Risk assessment
- Early cancer detection
- Detection of metastasis and recurrence
- Clinical guidelines
- Nuclear magnetic resonance

ENDOCRINE AND IDIOPATHIC CARCINOGENESIS
- Female genital tract
- Breast cancer
- Hepatic metabolism of steroids
- Thyroid cancer
- Prostatic and testicular cancer

CULTURAL PRACTICES
- Origins and reasons
- Difficulties of change
- Education in disease prevention: social impact
- Role of mass media
- Education in school
- Legislation

ENVIRONMENTAL INTERRELATIONS IMPLEMENTATION WORKSHOP
- Lessons from β-naphthalene
- Asbestos
- Agrochemicals (including agent orange example)
- Food stuffs (natural, artificial, Bracken fern, aflatoxins
- Air pollution
- Radiation pollution

ISPO Suite 303 207 East 85th Street New York, N.Y. 10028 USA

SCIENTIFIC PROGRAM

The program includes overview lectures, panels, poster sessions, scientific exhibits and special workshops. Reports will be presented on recent progress in multifactorial etiology of oncogenesis, molecular biology, identification of high-risk groups, tumor susceptibility, and clinical and laboratory manifestations of cancer, including tumor markers. Participants include the clinician, epidemiologist, pathologist, experimental oncologist, immunologist, socioeconomist, educator and members of the health care team.

IMPLEMENTATION WORKSHOPS

Special workshops are designed for critical appraisal of current data. Discussions will concentrate on actions to be taken and on the implementation of existing knowledge for effective cancer control by primary and secondary prevention.

PANELS ON CLINICAL ONCOLOGY OF SPECIFIC SITES

Daily panel topics include:

- epidemiology
- carcinogenic factors
- predisposing factors
- precancerous conditions
- markers for risk assessment
- detection and diagnosis by cytology, endoscopy, radiology, imaging, enzymology, immunology, ultrasound, histology, and other modalities
- management following detection
- prognostic determinants
- prevention

ISPO CANCER CONTROL AWARDS

ISPO is pleased to offer awards for original research that may lead to improved cancer control in:

- Tumor markers for risk assessment;
- Risk factors and their control in developing countries; and
- Tumor markers for detection of early neoplasms.

Applications are available upon request

GENERAL INFORMATION AVAILABLE

- Award applications
- Symposium brochure
- Accompanying persons program
- Special airfares
- Tours to Prague, Budapest, Salzburg
- Opera, concert and seasonal celebrations
- ISPO membership information

CALL FOR ABSTRACTS

Abstracts are invited for poster sessions and podium presentations on program-related topics. Deadline for receipt of abstracts: JULY 23, 1984.

FELLOWSHIPS

E M B O
European Molecular Biology Organization
LONG TERM FELLOWSHIPS IN MOLECULAR BIOLOGY AUTUMN 1984 AWARDS
Next deadline: August 15, 1984

EMBO long term post-doctoral fellowships are awarded to promote the development of molecular biology and allied research in Europe and Israel. To be eligibile a candidate must hold a doctorate degree and the exchange must involve a laboratory in Western Europe or Israel. EMBO fellowships are not, however, awarded for exchanges between laboratories within any one country. Long term fellowships are awarded initially for one year, but depending on a review of progress, they be renewed for a second year. In cases of exceptional scientific merit renewal for a third year is possible. The fellowship comprises a return travel allowance for the fellow and any dependents and a stipend and dependents' allowance.

Since the selection procedure may include an interview, candidates are requested to respect the deadline for complete applications which is August 15, 1984. Successful candidates will be notified of their awards immediately after the meeting of the selection committee, which is on October 29, 1984.

Application forms and further details may be obtained from Dr J. Tooze, Executive Secretary, European Molecular Biology Organization, Postfach 1022.40, 69 Heidelberg 1, F.R. Germany. (W1016)E

Clare Hall, Cambridge

Research Fellowships in Physical and Biological Sciences

The Governing Body of Clare Hill proposes to elect two or more non-stipendiary Research Fellows for a period of three years, starting not earlier than October 1984, to work in mathematics, the physical or biological sciences, or technology. There are no restrictions on age or sex.

The closing date for applications is 14th July 1984.

Application forms may be obtained from Clare Hall, Herschel Road, Cambridge (Tel. Cambridge 63330). (2164E)E

UNIVERSITY OF ABERDEEN

INSTITUTE OF ENVIRONMENTAL AND OFFSHORE MEDICINE

POSTDOCTORAL FELLOWSHIP

Applications are invited from suitably qualified graduates for a one-year appointment to the Institute. The work will involve investigation into the incidence of decompression sickness in commercial divers following air-diving in the UK sector of the North Sea with a view to identifying factors which might contribute to the condition. Applicants should have a working knowledge of diving techniques. Statistical/epidemiological experience would be an advantage. Further details available from Dr T Shields, Tel 0224 684432.

Salary on the Range IA scale for Research and Analogous Staff, £7,190 — £11,615 per annum (under review) with appropriate placing.

Application forms and further particulars from The Secretary, The University, Aberdeen, with whom applications (2 copies) should be lodged by 30 June 1984. (2187)E

THE DIABETIC ASSOCIATION
R.D. LAWRENCE RESEARCH FELLOWSHIPS

The Association seeks applications from graduate scientists or medically qualified persons working in the field of diabetes mellitus for the above Fellowships established in memory of Dr. R.D. Lawrence, the founder of the British Diabetic Association.

The Fellowships are for two years and the salary will be paid at registrar or equivalent university scales.

The closing date for applications is 25th June 1984 and applicants must be available for interview on 4th July 1984.

Forms available from: The Assistant Secretary, The British Diabetic Association, 10, Queen Anne Street, London, W1M 0BD. Tel: 01-323 1531. (2200)E

VICTORIA UNIVERSITY OF WELLINGTON
New Zealand

UGC POSTDOCTORAL FELLOWSHIPS

Applications are invited from suitably qualified persons who are no more than 35 years of age. Priority will be given to awards in current growth research areas in science in this country, and applications are invited in the following areas: Biochemistry, Botany, Chemistry, Computer Science, Geography, Geology, Geophysics, Mathematics, Operations Research/Statistics, Physics, Psychology, Zoology.

Conditions of Appointment and method of applications are available from the Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF, or from the Administrative Assistant (Appointments), Victoria University of Wellington, Private Bag, Wellington, New Zealand, with whom applications definitely close on 16 July 1984. (2207)E

UNIVERSITY OF ROCHESTER

NEUROBIOLOGY OF AGING TRAINING

for M.D's and Ph.D's. Several fellowships, supported by the National Institute on Aging, are now available for Ph.D's and post-residency M.D.'s who are interested in research training in the neurobiology of ageing. We particularly encourage applicants with diverse backgrounds who wish to apply their past training to problems of the aging CNS. Such backgrounds include molecular biology, biochemistry, pharmacology, neurology, psychiatry, medicine, gerontology, neural sciences, and others. The training program offers an intense research apprenticeship, brief circulation through a variety of laboratories, seminars, and clinical correlations. Twenty potential preceptors are in the Departments of Anatomy, Brain Research, Medicine, Neurology, and Psychology.

Apply to: **Dr Paul D. Coleman, Department of Anatomy, University of Rochester, Medical Center, Rochester, N.Y. 14642.** (NW550)E

POSTDOCTORAL FELLOWSHIP — Research Associate to study molecular cloning and genetic engineering with animal tissues or plant cells. Send cv to Dr J P Thirion, Microbiology Department, Faculty of Medicine, Sherbrooke, P Que, Canada J1H 5N4. (NW563)E

ASSISTANTSHIPS

IMPERIAL COLLEGE OF SCIENCE AND TECHNOLOGY
Biophysics Section

DEPARTMENT OF PHYSICS

RESEARCH ASSISTANTSHIPS IN PROTEIN CRYSTALLOGRAPHY

Post-Doctoral Research Assistantships are available on a programme of research into protein structure by X-ray crystallography. An initial appointment can be made for up to three years, but further extension is likely. Two posts are available. One requires an experienced protein crystallographer: the other would suit a young PhD with a knowledge of crystallography.

Apply as soon as possible to Prof D M Blow, RS, Blackett Laboratory, Imperial College, London SW7 2BZ, including a brief CV and the names of two referees. (2183)P

UNIVERSITY OF NOTTINGHAM

DEPARTMENT OF BIOCHEMISTRY

POSTDOCTORAL RESEARCH ASSISTANT

Applications are invited for a Postdoctoral Research Assistantship to work on the isolation and reconstitution of brain D_2 dopamine receptors. The project is funded by MRC and is initially for one year (starting from October 1st, 1984), renewable for a further two years. The salary is on the 1A scale starting at £7,190 per annum.

Applicants should send a curriculum vitae including the names of three referees to Dr P G Strange, Department of Biochemistry, University of Nottingham Medical School, Queen's Medical Centre, Nottingham NG7 2UH, as soon as possible. (2154)P

CONFERENCES and COURSES

NATO ADVANCED STUDY INSTITUTE

Radiation Carcinogenesis and DNA Alterations Corfu, Greece October 7-20, 1984

A series of lectures, tutorials and panel discussions will focus on how radiation-induced DNA alterations might be involved in radiation carcinogenesis. Topics will include activation of oncogenes, mutational alterations, chromosomal rearrangements and the possible role of DNA repair. Carcinogenesis in animals and *in vitro* transformation will be discussed as well as model implications for quantitative human risk assessment.

Faculty includes: Dr R.E. Albert, N.Y., U.S.A.; Dr A. Balmain, Glasgow, U.K.; Dr G.W. Barendsen, Rijswijk, N.L.; Dr J. Broerse, Rijswijk, N.L.; Dr F.J. Burns, N.Y., U.S.A.; Dr P. Cerutti, Lausanne, Switzerland; Dr K.H. Chadwick, Wageningen, U.K.; Dr S.B. Field, London, U.K.; Dr E.M. Fielden, Harwell, U.K.; Dr A.H. Kellerer, Wurzburg, D.R.F.; Dr J.B. Little, Boston, U.S.A.; Dr M. Paterson, Chalk River, Canada; Dr A. Rauth, Toronto, Canada; Dr G. Silini, Vienna, Austria; Dr I.P. Sinclair, New Jersey, U.S.A.; Dr K.C. Smith, California, U.S.A.; and Dr A.C. Upton, N.Y., U.S.A.

The course is open to scientists and postdoctoral workers in cell and molecular biology, radiation biology or biochemistry. Assistance to defray living costs, etc. will be available.

For further information contact: Dr F.J. Burns, NYU Department of Environmental Medicine, 550 First Ave., New York, N.Y. 10016. (NW564)C

UNIVERSITY OF ST ANDREWS
MSc Course in Radiation Biophysics

This taught course occupies a calendar year with a 6 month formal component and a 6 month research project.

The course is interdisciplinary and run jointly by the Departments of Anatomy and Experimental Pathology and Physics. It is structured to accommodate those qualified either in the physical sciences or the life sciences and caters for differing interests and career intentions of students. It is suitable, for example, for those considering careers in research with, and application and control of, radiation in science, industry, medicine and power production. Research Council scholarships (MRC) are available.

The course is that previously provided by the Department of Medical Biophysics at Dundee University.

Enquiries and applications to Dr A.C. Riches, Department of Anatomy and Experimental Pathology, University of St Andrews, St Andrews, Fife KY16 9TS. (2029)C

APPOINTMENTS WANTED

Advertise your qualities and qualifications through the most influential science weekly in the world at a special reduced cost of *25p a word*. Personal Box Numbers £2).

Advertisements must be pre-paid and sent to: Nature Classified (Appts Wtd), 4 Little Essex Street, London WC2R 3LF. (890)B

UNIVERSITY OF GLASGOW
Institute of Physiology

RNIB RESEARCH STUDENTSHIP

Quantitative study of synapse formation in normal and amblyopic retinae re maturity of ganglion cell receptive field. Involves electron microscopy with scope for diversification. Excellent facilities: full training given. Good Honours degree in Physiology, Anatomy or related subject required. Start 1st October for 3 years: registration for PhD degree.

Applications, including 2 referees, to Dr J D Morrison, from whom further particulars are available (tel 041 339 8855 ext 552). (2169)C

UNIVERSITY OF EDINBURGH
DEPARTMENT OF METEOROLOGY

NERC STUDENTSHIP

Applications are invited for a Research Studentship on 'The Meteorological Influences on the Distribution of Rainfall Acidity in the U.K.' This is a case studentship with the Institute of Terrestrial Ecology, Edinburgh. Candidates should have or expect to obtain in 1984, a first or upper second class honours degree in a physical science or in environmental science. Further details can be obtained from Dr K J Weston, Department of Meteorology, University of Edinburgh, Edinburgh EH9 3JZ. (2216)F

STUDENTSHIPS

Portsmouth Polytechnic
DEPARTMENT OF BIOLOGICAL SCIENCES

1. Research Assistantship
Applications invited for a ROSCM funded post to investigate marine microbial fouling of ship.
Salary scale: £4,515 – £5,649 per annum (under review)

2. One SERC Studentship:
a) Ultrastructural and immunological studies of developing stages of nematode parasites
b) Microbial deterioration of timber
c) An investigation of post germination attachment in some common marine fouling algae.

Closing date for the above posts 18th June 1984.

3. MSc Course in Biodeterioration of Materials
SERC Advanced Course studentships available for suitably qualified students.

Application forms and further details for (1) from the Personnel Office, Nuffield Centre, St Michaels Road, Portsmouth. Tel: (0705) 825451. Ref: B

Further details for (2) and (3) from Administrative Assistant, Department of Biological Sciences, Portsmouth Polytechnic, King Henry 1 Street, Portsmouth. (2213)F

UNIVERSITY OF NOTTINGHAM
and
TROPICAL DEVELOPMENT RESEARCH INSTITUTE

RESEARCH STUDENTSHIP
Stability of tropical fish muscle proteins

Applications are invited from those holding a first or second class honours degree in food science, chemistry, biochemistry or related discipline for a TDRI research studentship tenable in the Department of Applied Biochemistry and Food Science. The successful candidate will be required to register for a higher degree of the University of Nottingham and will be engaged full-time on a programme designed to evaluate the factors affecting the stability of tropical fish muscle proteins during processing.

The scholarship is for 3 years.

Applicants should forward a curriculum vitae including the names of two referees to:- Dr R G Bardsley, Dept of Applied Biochemistry & Food Science, University of Nottingham, School of Agriculture, Sutton Bonington, Loughborough, Leics LE12 5RD. (Telephone Kegworth 2386) (2179)F

TRENT POLYTECHNIC
DEPARTMENT OF LIFE SCIENCES

SERC CASE STUDENTSHIP

Applications are invited for the above studentship. The project, in collaboration with Bush Boake Allen Ltd, London, will investigate the use of microorganisms or enzymes extracted from them in the production of fragrances and flavours.

Applicants should hold or expect to hold a first or upper second class honours degree in biochemistry, microbiology, biotechnology or related subjects.

Further details and form of application are available from the Staff Officer, Trent Polytechnic, Burton Street, Nottingham NG1 4BU. Closing date: 18 June 1984. (2155)F

THE UNIVERSITY OF LEEDS
DEPARTMENT OF PLANT SCIENCES

RESEARCH STUDENTSHIP

Applications are invited for the above postgraduate studentship from final undergraduates or from recent graduates with a good honours degree in the agricultural sciences or in plant biology. The student will work in a group funded by ICI to study the growth and physiology of winter barley and will be registered for a higher degree on a full-time basis.

Further details can be obtained from Professor Elston, Department of Plant Sciences, The University, Leeds LS2 9JT, (tel (0532) 431751 Ext 377) to whom applications, with the names and addresses of two referees, should be submitted as soon as possible. (2160)F

NUTRITIONAL CONSULTATIVE PANEL
of the
UK Dairy Industry
is offering a

POST GRADUATE STUDENTSHIP

for work, possibly leading to a higher degree in a British University or Research Institution on a Nutritional subject related to: Milk and Milk Products in the Human Diet. Examples of subjects which the Panel has identified are:
1) the role of calcium in cow's milk
2) the role of cow's in the weaning of human infants.

Other subjects will be considered. Salary will follow MRC guidelines. Apply in writing, maximum 500 words, before 22nd June 1984 to: The Secretary, Nutritional Consultative Panel, Giggs Hill Green, Thames Ditton, Surrey KT7 0EL, including proposed department where work will be carried out, curriculum vitae and names and addresses of 2 referees. (2182)F

STUDENTSHIPS

UNIVERSITY OF BATH

DEPARTMENT OF BIOCHEMISTRY

Students who have or are expecting to obtain, an upper second class degree are invited to apply for this

SERC STUDENTSHIP

The topic of research is the Molecular biology of dormancy in plants. The involvement of gene expression in the maintenance and breaking of dormancy will be studied. Purification of some of the enzymes of carbohydrate metabolism and their messenger RNA's will be undertaken with the ultimate aim of inserting cDNA copies into various plasmid vectors. It is expected that this work will give insight into the regulation and control of dormancy.

Applications with a curriculum vitae and the names of two referees should be sent to Dr P P Rutherford, Biochemistry Department, 4 West University of Bath Bath BA2 7AY. (2197)F

UNIVERSITY OF YORK

DEPARTMENT OF BIOLOGY

Applications are invited for a postgraduate studentship leading to a DPhil to study either immunological mechanisms in chronic relapsing experimental allergic encephalomyelitis, an animal model for multiple sclerosis or the effects of neurotropic virus infections on defined populations of central nervous system cells in culture. Candidates must have (or expect to gain) a First or Upper Second class degree. The studentship is funded by the Multiple Sclerosis Research Fund Ltd. on terms and conditions similar to Research Council studentships. For further information contact Dr M G Rumsby or Dr A J Suckling in the Department of Biology, University of York, Heslington, York YO1 5DD. (2221)F

QUEEN MARY COLLEGE
(University of London)

School of Biological Sciences

NERC RESEARCH STUDENTSHIPS

Two NERC Research Studentships are available for postgraduate research on the following topics:

(1) Reproductive investment and transmission success in helminth life cycles;

(2) Trace metal detoxification in crustaceans: separate or integrated systems?

Topic (1) will be supervised by Dr R C Tinsley; topic (2) by Dr P S Rainbow.

Applications should be sent to the relevant supervisor by 14th June, at the following address: School of Biological Sciences, Queen Mary College, Mile End Road, London, E1 4NS. (2205)F

UNIVERSITY OF EDINBURGH

DEPARTMENT OF GENETICS

A POSTDOCTORAL/ RESEARCH ASSOCIATE

vacancy exists for a scientist with experience of recombinant DNA/DNA sequencing. The work will be concerned with a study of host/virus nucelotide sequence homologies. The post is available from 1st July 1984, and is grant supported until 30th September 1985 in the first instance. Salary according to age and experience on academic scale £6,310 to £11,615.

Further particulars available. Applications with cv and names and addresses of two referees should be addressed to the Secretary's Office, Old College, South Bridge, Edinburgh.

Please quote reference No. 5175. (2226)F

THE UNIVERSITY OF LEEDS

DEPARTMENT OF CARDIOVASCULAR STUDIES

MRC STUDENTSHIP

Applications are invited for an MRC studentship commencing on 1 October 1984. The project is to investigate the convergence of cardiac and baroreceptor afferent fibres onto single neurones in the modulla oblongata.

Applicants should possess or expect to obtain a first class or upper second class degree in Physiology or a related discipline.

Applications, including the names of two academic referees, should be submitted to Dr P E McWilliam, Department of Cardiovascular Studies, University of Leeds, Leeds LS2 9JT. (2225)F

UNIVERSITY OF NOTTINGHAM

DEPARTMENT OF BIOCHEMISTRY

SERC POSTGRADUATE STUDENTSHIP IN BACTERIAL MOLECULAR BIOLOGY

Applications are invited for research on the molecular biology of either (i) RNA polymerase (ii) the multivalent vitamin B_{12} receptor, or (iii) methionine biosynthesis in Escherichia coli.

The studentship will commence in October 1984; registration is initially for an M Phil.

Applicants possessing a 2(i) or higher in an appropriate degree should send a curriculum vitae and the names of two referees to Dr Robert E Glass, Department of Biochemistry, Queen's Medical Centre, Nottingham NG7 2UH (Telephone: 0602-700111 ext 3395) from whom further information may be obtained. (2153)F

EAST MALLING RESEARCH STATION

FRUITERERS STUDENTSHIP

Applications are invited for a postgraduate studentship award by the Worshipful Company of Fruiterers for research into factors which affect eating quality of apple fruits produced by modern growing methods.

Applicants should have, or expect to obtain, a First or Upper Second class honours degree in botany, horticulture or a related subject, and must be able to commence the three year studentship in August 1984 at the latest.

Application form and further details from the Deputy Secretary, East Malling Research Station, Maidstone, Kent ME19 6BJ.

Closing date for applications is 15 June, 1984. (2185)F

KING'S COLLEGE LONDON
(University of London)

DEPARTMENT OF BIOCHEMISTRY

Applications are invited for a SERC-CASE post-graduate studentship in association with Ciba-Geigy Pharmaceuticals Division, Horsham. The project will involve studies on the properties and regulation of phospholipase C in human blood platelets with especial reference to phosphoinositide metabolism.

Applicants should have, or expect to obtain, a First or Upper Second Class Honours degree in Biochemistry or a relevant related discipline.

Applications, including the names and addresses of two referees, should be sent to Professor M C Scrutton, Department of Biochemistry, King's College London, Strand, London WC2 2LS to arrive as soon as possible, preferably before June 7 1984. (2171)F

GEORGE HENRY LEWES STUDENTSHIP

Applications are invited for this Studentship to pursue original investigation in Physiology. Appointment may be from 1 October 1984 for one year with a possibility of renewal for up to two further years. The award will provide an annual maintenance grant in line with the maintenance element of a Research Council research studentship; and the Trustees will pay University and College fees for the holder at the rates charged to science research students from the UK.

Candidates should by 16 July 1984 send (a) a statement of their qualifications and their need for pecuniary help, (b) the subject of their proposed research, and (c) the names and addresses of two referees, to Professor R D Keynes, Physiological Laboratory, Downing Street, Cambridge CB2 3EG, from whom further particulars may be obtained. (2217)F

REGIONAL NEUROLOGICAL CENTRE
Newcastle General Hospital

DEPARTMENT OF SURGERY (NEUROSURGERY)

EXPERIMENTAL STROKE
PhD Studentship
(Junior Research Associate)

Applications are invited from suitably qualified candidates (1 or 2.1 in physiology or biochemistry) for the above post, which is funded for 3 years by an MRC Project Grant.

Mechanisms of loss of neurological function in acute stroke will be examined: the studies will provide experience of a range of acute experimental techniques, and an opportunity to develop appropriate topographical biochemical methods.

Further information may be obtained from Mr A J Strong, Regional Neurological Centre, Newcastle General Hospital, Westgate Road, Newcastle upon Tyne NE4 6BE, tel Newcastle 738811, ext 647. Closing date for applications (to include cv and names of 2 referees) 18th June. (2222)F

QUEEN ELIZABETH COLLEGE
Kensington
(University of London)

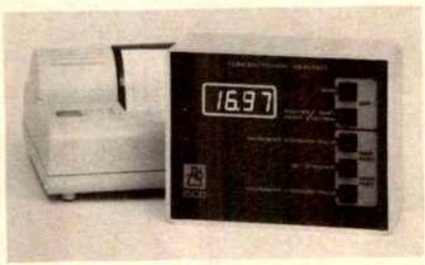
DEPARTMENT OF PHYSIOLOGY

PHD STUDENTSHIP

Applications are invited for a Research Studentship in the Department of Physiology, tenable for three years commencing October 1984. The successful candidate will work with Dr G E Mann on the hormonal regulation of membrane transport in the normal and diabetic pancreas. The study will involve assessing the influence of islet (insulin, glucagon and gastrointestinal hormones or rapid amino acid uptake by the exocrine epithelium.

The successful applicant would be expected to register for a higher Degree. Candidates should possess or expect to obtain, a First or Upper Second Class Degree in Physiology Biochemistry or a related subject.

The Department has excellent research facilities for the above project and other closely related topics. Research and teaching will be strengthened by the merger of Queen Elizabeth College and Chelsea College with King's College London.



Applicants should apply in writing including their curriculum vitae and the names of two referees to Professor D L Yudilevich, MD, Department of Physiology, Queen Elizabeth College, University of London, Campden Hill Road, London W8 7AH. (2203)F

Typesetting: J.W. Arrowsmith Ltd, Bristol and Outline Graphics Ltd., London EC4Y 0HP. NOW DO COMPUTING COLORIMETRY WITH YOUR ISCO UA-5 DETECTOR

No more manual calculation of each concentration — this new accessory for your UA-5 absorbance detector will do it for you.

The microprocessor-controlled Concentration Readout saves time and improves your accuracy. It converts sample absorbance to concentration, then displays and prints it directly in any units you choose: mg/ml, g%, mol/ℓ, lb/gal ... whatever. Use it with the UA-5 to automate such UV-VIS colorimetric assays as enzymes at 340 or 365 nm,

proteins or nucleic acids at 214 or 254 nm, or heme proteins at 405 nm.

You can use the Concentration Readout to read solutions in spectrophotometer-type cuvets; in a semi-automatic sipper system using the WIZ smartpump/dispenser to carry samples through a UA-5 flow cell; and in a fully automated system with the ISIS AutoSampler, WIZ and printer. In the automated system, you can print sample number and concentration of up to 114 samples without operator intervention.

The Concentration Readout is our latest accessory to keep the UA-5 ahead of other detectors you could buy. A UA-5 has 18 available wavelengths from 214 to 660 nm and full-scale sensitivity ranges from 0.002 A to 2.0 A. You can choose from 14 flow cells for applications ranging from μLC (0.12 μl volume!) and HPLC to large-scale prep work. Use it to scan electrophoresed gels or centrifuged density gradients, monitor simultaneously two separate columns or one column at two wavelengths, and, of course, to read solution absorbance in lift-out cuvets. And now, with the Concentration Readout, the UA-5 gives you those readings automatically and directly in the units you want.

For more information about the UA-5 lab system, write ISCO, P.O. Box 5347, Lincoln, Nebraska 68505, U.S.A.

SCIENCE IN THE LOW COUNTRIES

ARCHIVED BY ITHAKA

"So what makes it better than mine?"
"Well I've stopped collecting fractions. I just collect peaks."

"Really?"

"Yes, it's the only peak-sensing HPLC collector that does."

"So?"

"So for preparative HPLC it's perfect. It's got a built-in slope detector that can tell the difference between peaks and non peaks."

"How about unresolved peaks?"

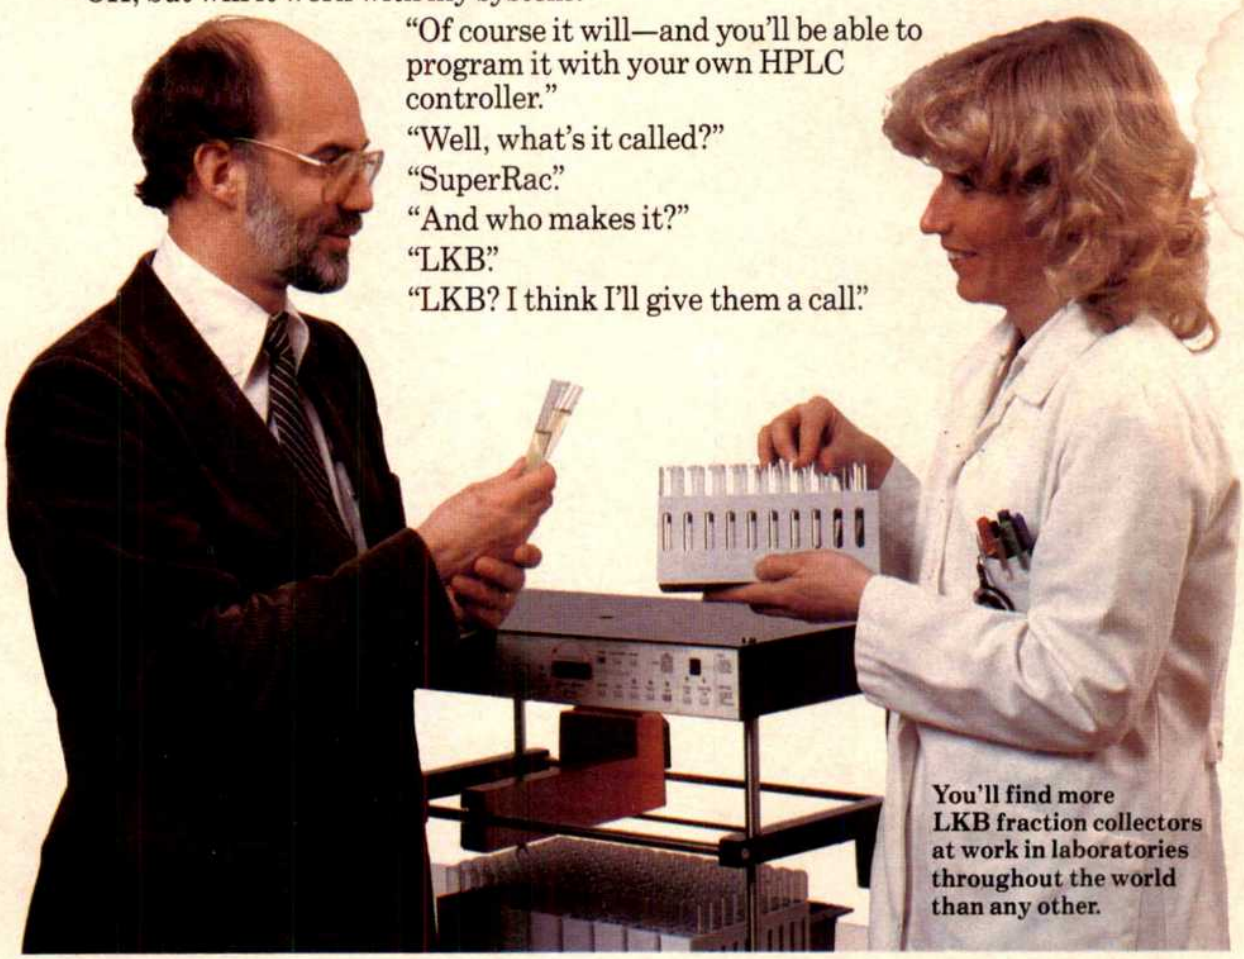
"Them too, and it automatically compensates for drifting baselines, peak asymmetry and band broadening."

"Yeah, but will it really work with fast eluting peaks?"

"Listen, this fraction collector's so intelligent, it'll collect anything you want, any time, any place. So however sharp the peak is you'll always get it — right in the tube. And it's got over 300 tubes to collect in."

"OK, but will it work with my system?"

"Of course it will—and you'll be able to program it with your own HPLC controller."



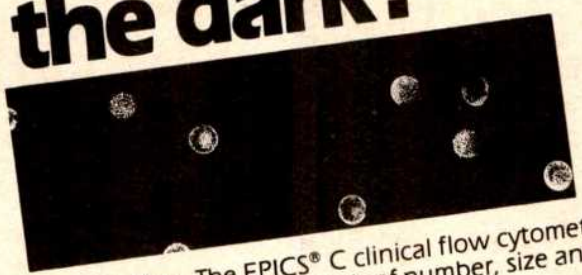
"Well, what's it called?"

"SuperRac."

"And who makes it?"

"LKB."

"LKB? I think I'll give them a call."



You'll find more LKB fraction collectors at work in laboratories throughout the world than any other.

Does your fluorescent analyser keep you in the dark?

New from Coulter. The EPICS® C clinical flow cytometer analyses and sorts cells routinely on the basis of number, size and fluorescence by use of programmable protocols.
No fluorescent microscope analyses, no darkened rooms, no highly trained dedicated operators.

● differentiation of white blood cells (or any biological cells) ● fluorescence determination by specific antigen characteristics ● range of compatible monoclonal antibodies available (e.g. for T & B cell ratio, T helper/T suppressor) ● physical sorting of populations into sub-populations for further study ● high specificity allows previously inseparable cells populations to be determined ● automatic operation allows short 'half life' fluorescent determinations to be made.

Epics® C

Automatic cell analyser and sorter at an 'analyser only' price

Circle No.05 on Reader Service Card.

Recent developments in molecular biology, many of which have been described by their authors in *Nature*, are helping to clarify the causes of cancer. With each passing week, more and more people consider that a full understanding of cancer cannot be long delayed. But the implications for physicians and their patients are still entirely unclear.

Organized and presented by NATURE, the international journal of science

Perhaps the most important international conference you could attend in 1984. Devoted to the recent contributions of molecular biology to the understanding of malignant disease.

For Research Scientists and Clinicians

IN SEARCH OF UNDERSTANDING...

THE MOLECULAR BIOLOGY OF CANCER

This is why NATURE has chosen to devote its third international conference to an occasion when researchers in the life sciences and clinicians can assess the importance of recent developments in molecular biology for the understanding and ultimately for the treatment of cancer.

SEPTEMBER 10, 11, 12, 1984
BOSTON PARK PLAZA HOTEL

Park Plaza at Arlington Street
Boston, MA 02117 U.S.A.

The conference program has been designed for two groups of people—researchers in the life sciences anxious to learn about and discuss the latest developments in the molecular biology of cancer, and physicians who consider that these developments may eventually affect their own work with patients.

Participation in the conference will be restricted so as to provide opportunities for those participating to mix with and to question those responsible for the latest research.

To this end, the leading scientists making formal presentations will also take part in two-hour round table discussions, providing an ample and unusual opportunity for participants to take part in detailed discussions and to make short presentations of their own.

To take part in this important and novel conference, register now and book your rooms (also limited) at the Boston Park Plaza Hotel and Towers.

TO REGISTER FOR THE CONFERENCE: Return the form appearing in this advertisement, with your check, or an authorized purchase order from your organization.

EARLY REGISTRANTS SAVE $50: If your registration and payment is received by July 1, you may deduct $50 from the regular full registration fee of $325. You pay only $275.

THE SETTING: Boston Park Plaza Hotel and Towers, Boston located at Park Plaza and Arlington Street, just off the famous Boston Public Gardens and Common.

ROOM RESERVATIONS: A large block of rooms has been set aside for attendees, but we do suggest that you reserve your accommodations early, to avoid disappointment. Rooms must be reserved directly with the Hotel, at (617) 426-2000, or 800-225-2008, Telex: 710 321 1088. Be certain to mention your participation in the "Nature Conference", to take advantage of these special lower rates: Singles: $70, 80 & 85; Double: $85, 95 & 100.

CONFERENCE DINNER: The Conference dinner will be held on Tuesday evening, September 11th, in the Imperial Ballroom. TO INSURE SEATING AT THE CONFERENCE DINNER, please include your dinner ticket requirements and payment of $25 per person with your Registration.

POSTER SESSIONS: A limited space for posters will be made available. Please write to: Poster Sessions Editor, Nature Publishing Company, 15 E 26 St., N.Y., NY 10010.

RECRUITMENT CENTER: Private meeting rooms and staff will be provided for recruitment executives and scientists to discuss employment opportunities. Contact: Miss Gene Fein, Recruitment Services Manager, Nature Publishing Co., 15 E. 26 St., N.Y., NY 10010, (212) 689-5900.

THE MOLECULAR BIOLOGY OF

CANCER

Conference Program
September 10-12, 1984
Boston Park Plaza Hotel

Daily Themes:

DAY 1 - ONCOGENES,
DAY 2 - THE CANCER CELL,
DAY 3 - PROSPECTS/PROBLEMS.

DAY 1

MONDAY, 10 September
Exhibition Viewing: 8:30am— 6:30pm
Recruitment Center: 9:30am— 6:00pm

ONCOGENES AND GROWTH FACTORS — WHAT THEY ARE AND WHAT THEY DO

9:00— 9:15	Chairman
9:15—10:00	Oncogenes *R. Weinberg (MIT)*
10:00—10:45	Growth factors *M. Sporn (NIH)*
11:15—12:00	HTLV *R. Gallo (NIH)*
12:00—12:30	Clinician's View *S. Broder (NIH)*
2:00— 4:00	Roundtables with morning speakers
4:30— 5:30	The Cancer Cell *J. Cairns (Harvard)*

DAY 2

TUESDAY, 11 September
Exhibition Viewing: 8:30am— 6:30pm
Recruitment Center: 8:30am— 6:00pm

THE CANCER CELL — HEREDITARY CANCER, TUMOR PROMOTERS AND CARCINOGENESIS

9:00— 9:15	Chairman
9:15—10:00	Gene Regulation *P. Leder (Harvard)*
10:00—10:45	Hereditary cancer *R. White (Utah)*
11:15—12:00	Carcinogens and promoters *I.B. Weinstein (Columbia)*
12:00—12:30	Clinician's View *F. Gilbert (Mt. Sinai)*
2:00— 4:00	Roundtables with morning speakers
4:30— 5:30	NCI program

DAY 3

WEDNESDAY, 12 September
Exhibition Viewing: 8:30am— 3:00pm
Recruitment Center: 8:30am— 3:00pm

PROSPECTS AND PROBLEMS— DRUG RESISTANCE, MONOCLONAL ANTIBODIES AND NEW DRUGS

9:00— 9:15	Chairman
9:15—10:00	Diagnostics and therapeutics *G. Todaro (Oncogen)*
10:00—10:45	Immunotoxins *J. Uhr (Texas)*
11:15—12:00	Drug resistance *A. Varshavsky (MIT)*
12:00—12:30	Clinician's View *J. Gutterman (Houston)*
2:00— 4:00	Roundtables with morning speakers
4:00— 4:45	Prospects
4:45	Closing remarks

TO REGISTER FOR THE CONFERENCE, mail this form with your payment.

Please reserve my place at

The Molecular Biology of CANCER

I wish to reserve _____ Conference Registration(s) in the names of: *(Please print or type)*

_____

and _____ Seats at the Tuesday Evening Dinner in the names of:

_____

NEW FROM AMERSHAM

Human Placental Ribonuclease Inhibitor

This powerful non-competitive inhibitor of ribonucleases is isolated from human placenta and purified by affinity chromatography. Our product:

- can be used in a variety of applications e.g. to improve significantly the yield of products obtained in *in vitro* translation, *in vitro* transcription, cDNA synthesis and polysome isolation.
- is biologically tested in a wheat germ lysate system.
- has been tested for compatibility with a eukaryotic *in vitro* transcription system.
- is available at a concentration of ⩾25000 units/ml and in two pack sizes

5000 units – code N.120Y 25000 units – code N.120Z

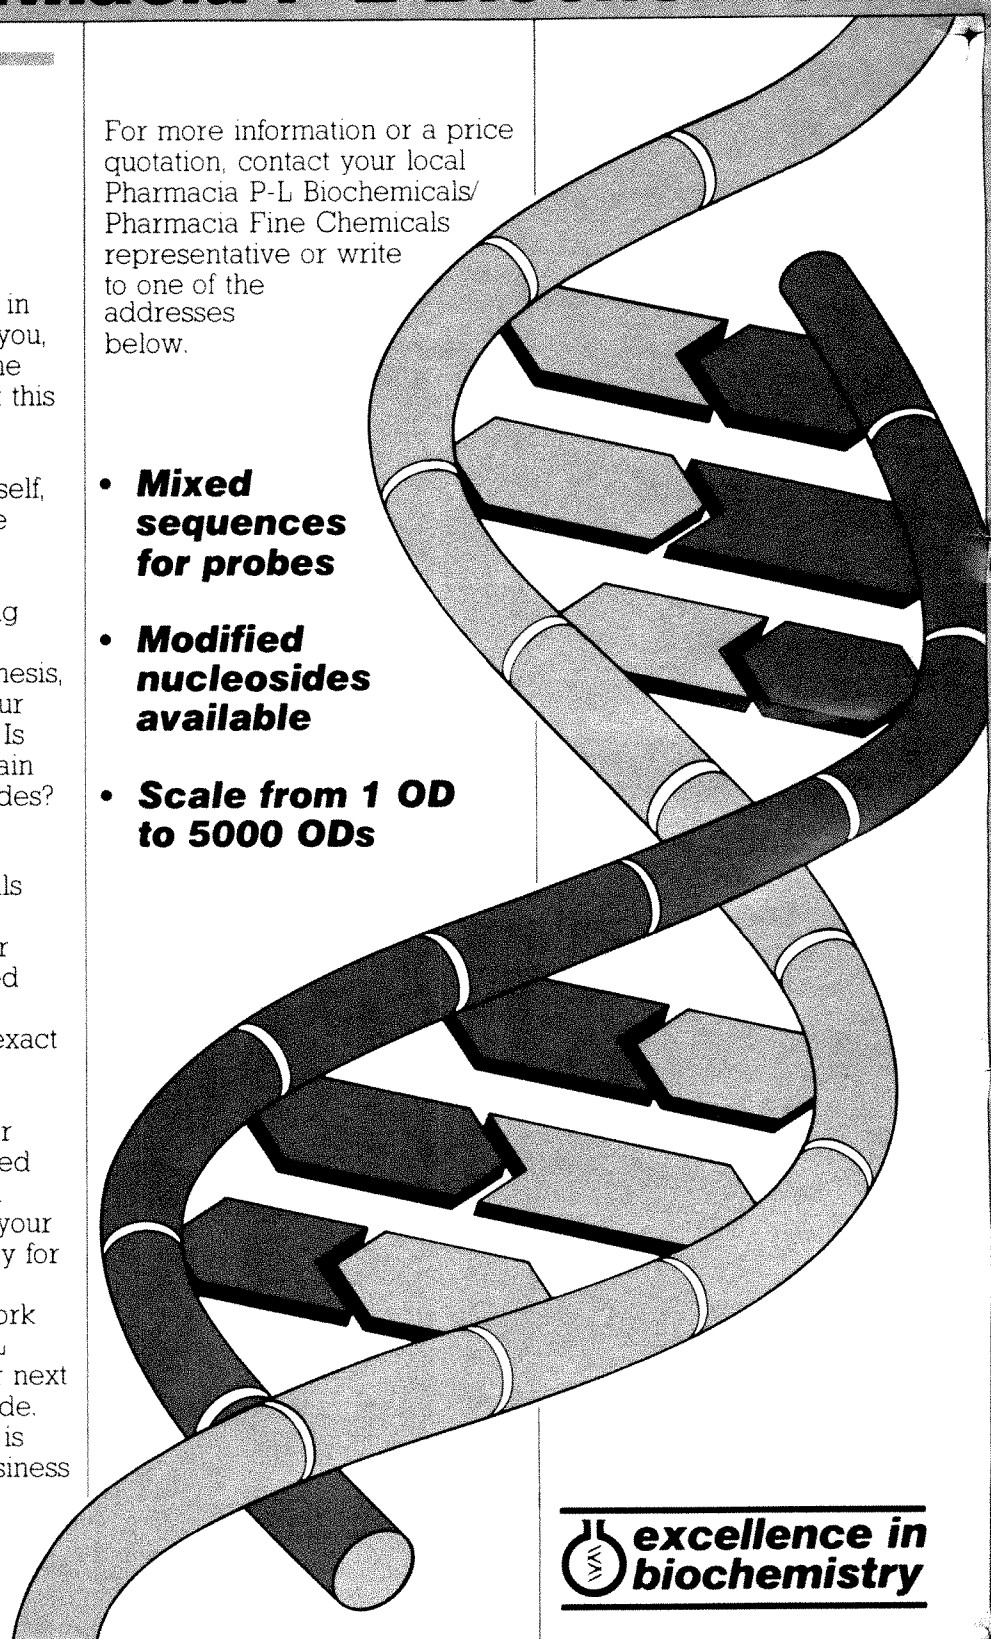
Custom Oligodeoxynucleotides From Pharmacia P-L Biochemicals



Make Discoveries, Not Reagents

Oligodeoxynucleotides of defined sequence are an increasingly important tool in research. This means that you, the researcher, must ask the question: "Where can I get this vital product?". You could synthesize and purify the oligodeoxynucleotide yourself, but this takes valuable time away from your research; instead of making new discoveries, you are making reagents! Expensive "gene machines" can do the synthesis, but you must still invest your time to purify the product. Is there no better way to obtain custom oligodeoxynucleotides?

The better way is to have Pharmacia P-L Biochemicals prepare your custom oligodeoxynucleotides. Our experienced team of skilled professionals can quickly synthesize and purify the exact sequence desired in the quantity that you require. Whether you need 1 OD or 5000 ODs, whether you need modified bases or a mixed sequence, we can supply your oligodeoxynucleotide ready for you to use. Put our custom synthesis experience to work for you—let Pharmacia P-L Biochemicals prepare your next custom oligodeoxynucleotide. Remember, your business is scientific research; our business is making your reagents.

For more information or a price quotation, contact your local Pharmacia P-L Biochemicals/ Pharmacia Fine Chemicals representative or write to one of the addresses below.

- ***Mixed sequences for probes***
- ***Modified nucleosides available***
- ***Scale from 1 OD to 5000 ODs***

SCIENCE IN THE LOW COUNTRIES

- *Will the policy of "concentrating" the universities in Holland and Belgium create more problems than it solves?*
- *Is Belgian science stagnating?*
- *What would be the effect of increased government control over Dutch research policy?*

These and other questions are examined in *Nature*'s special supplement on Science in the Low Countries.
Extra copies of this issue are available now from the address given below.

—GUIDE TO AUTHORS—

Authors should be aware of the diversity of *Nature*'s readership and should strive to be as widely understood as possible.

Review articles should be accessible to the whole readership. Most are commissioned, but unsolicited reviews are welcome (in which case prior consultation with the office is desirable).

Scientific articles are research reports whose conclusions are of general interest or which represent substantial advances of understanding. The text should not exceed 3,000 words and six displayed items (figures plus tables). The article should include an abstract of about 50 words.

Letters to *Nature* are ordinarily 1,000 words long with no more than four displayed items. The first paragraph (not exceeding 150 words) should say what the letter is about, why the study it reports was undertaken and what the conclusions are.

Matters arising are brief comments (up to 500 words) on articles and letters recently published in *Nature*. The originator of a Matters Arising contribution should initially send his manuscript to the author of the original paper and both parties should, wherever possible, agree on what is to be submitted.

Manuscripts may be submitted either to London or Washington (decisions being made only in London). Manuscripts should be typed (double spacing) on one side of the paper only. Three copies are required, each accompanied by copies of lettered artwork. No title should exceed 80 characters in length. Reference lists, figure legends, etc. should be on separate sheets, all of which should be numbered. Abbreviations, symbols, units, etc. should be identified on one copy of the manuscript at their first appearance.

References should appear sequentially indicated by superscripts in the text and should be abbreviated according to the *World List of Scientific Periodicals*, fourth edition (Butterworth 1963–65). The first and last page numbers of each reference should be cited. References to books should clearly indicate the publisher and the date and place of publication. Unpublished articles should not be formally referred to unless accepted or submitted for publication, but may be mentioned in the text.

Each piece of artwork should be clearly marked with the author's name and the figure number. Original artwork should be unlettered. Suggestions for cover illustrations are welcome. Original artwork (and one copy of the manuscript) will be returned when manuscripts cannot be published.

Requests for permission to reproduce material from Nature *should be accompanied by a self-addressed (and, in the case of the United Kingdom and United States, stamped) envelope.*

We should have our heads examined...

We changed the most reliable water bath shaker ever made!

Why add microprocessor technology to the most reliable shaker ever made? Why alter a good thing when so many of these G76 Water Bath Shakers are still operating after 20 and 30 years of continuous use.

We've never made a shaker that controls temperature so closely or speed so precisely. We've never made a shaker that monitors its own performance to give you self-diagnostic readout of operating parameters on the front panel or central computer.

Don't let the digital exterior fool you. The internal mechanism of the G76/D is virtually unchanged. To ensure a long life of uninterrupted shaking, we're still using the same time-tested triple eccentric drive. And we're still using the highest quality fractional horsepower motor made. That's the way we built them in the 1950's, and that's the way we're building them today.

The original G76 is still in production. But if you want to combine proven reliability with microprocessor technology to control temperature within 0.1 °C and speed to within 1 rpm, look into the G76/D.

Send today for our 42-page, full color shaker catalog. New Brunswick Scientific Co., Inc., P.O. Box 986, Edison, NJ 08818, or call your NBS Sales representative at 800-631-5417. In New Jersey, call 201-287-1200.

Revivifying Europe's research

The next European summit at Fontainebleau could be another dog-fight, spend time making speeches about European federation or — more prudently — find a middle course.

EUROPE may not be made in the few weeks ahead, but there is a danger that it could be broken. And certainly the month that lies ahead will be crucial for the whole enterprise. First come the European elections, only the second occasion on which representatives to the European Parliament have been chosen democratically and not simply nominated by their cronies. Then follows the next meeting of European political leaders at Fontainebleau, formally an occasion when the rest of Europe might thank President François Mitterrand of France for having been an energetic president of the Community (which would be true) but in practice more likely to be dominated by two quite different themes — the British Government's demand that it should be given a substantial rebate (say, £1,200 million) on the contributions it paid last year into the common budget, and the more general proposal that Europe, having made a bad job of creating a common market, should now go on to build a federal state. Between the ridiculous and the sublime, the serious opportunities at Fontainebleau are likely to be forgotten.

The survey of the condition of science in Belgium and the Netherlands which appears elsewhere in this issue points more accurately to some of the tasks that need to be attempted on a European scale (see p.491). Two of Europe's smallest states, in recent memory among the most prosperous, find themselves unexpectedly having to struggle to keep up with the times. As elsewhere, public budgets are being cut so as to escape inflation, the problems of catching up with the new technology are daunting and people worry that established institutions and ways of doing civil business may be damaged by too rapid a transition from the past to an uncertain future. In one way or another, the whole of Europe is similarly affected.

The calculation in the early 1950s was that if the common market that is the core of the Treaty of Rome could be made to function, the result would be an industrial population as large as any other in the world, prosperous and industrially creative. In the event, the common market has functioned, but only fitfully. In some respects, the arrangements have been an expensive joke (the butter mountain, the wine lake, and all that). In others (as at a host of national customs posts, which innocents may think should long since have disappeared), chauvinism has triumphed over legality. Public purchasing is still largely determined by public authorities, usually governments, in what seems to be the national interest. The result is that Europe is far from being the productive place the founding fathers foresaw. Those meeting at Fontainebleau should spend at least some time reminding themselves that their dream has not come true.

Chauvinism

Where they go from there depends on their estimate of what has gone wrong. To the extent that chauvinism is still an impediment to the efficient division of labour, it must be supposed that not all of the members of the common market have been serious all of the time. Nor are they now. The British Government is not the only political party whose representatives will be fighting next week's election on a platform which promises that national interests, general or particular, will be fiercely defended at Brussels. Even if these promises are not always kept in full, it is disappointing that they should be though necessary at all. The threatened fight at Fontainebleau over the British rebate could yet become the signal for the disintegration of the whole experiment.

The remedy, now as at the past two European summits (at Athens and Versailles) is that the participants should be patient, reckoning that their goal is a moving target, and that they should find other things to talk about than the issues on which they are most sharply divided. Here is a shopping list:

- Europe is alarmed at its technical inadequacies, for which reason the European Commission has been putting together programmes for collaborative research and development which must be transnational to attract support. But the Commission has put the cart before the horse. If the division of labour were economical (as one day it may be), industrial companies would shoulder responsibility for applied research, but Europe in general would have an important role to play in the support of more fundamental work, just as national governments now have. So why not begin in this neck of the woods, but slowly, recognizing that it will take time to weld Europe's academic and research community into a single entity, preserving its diversity the while?
- Europe is concerned that an efficient division of labour would leave some member states more prosperous than others in ways that would not automatically be offset by the migration of labour (formally made free under the existing rules, but inhibited by language and inertia). This fear is the seat of many of the restraints on the working of the common market now widely practised. But why not then follow the simple course, followed nationally in most of Europe, of arranging that the socially disadvantaged are somehow compensated from the well-being of others? The European social fund now administered from Brussels is too small to be significant and too discretionary to seem fair.
- Europe is by fits and starts scared stiff that it will once again become a battlefield, a danger made all the sharper by its knowledge that it is neither prosperous nor determined enough to defend itself. There can be no quick solution. The lack of resources is a more pressing restraint than the lack of will, while the problems of approaching the notion of a common defence would reawaken the arguments that made the 1950s wretched. But if the European Communities are to survive and to fulfil their promise, a start has to be made somewhere. Encouraging Europeans to join each others' armed services would be an interesting point, not much canvassed hitherto.

None of this quite lives up to President Mitterrand's eloquent espousal, in Strasbourg the other day, of the European Parliament's plan for a federal Europe, but that is inevitable. The mood has changed a great deal since the day in 1940 when the then British Prime Minister, Winston Churchill, flew to France to propose a political union of the two states. (The offer, hastily conceived, was turned down.) Curiously, life is altogether more serious now that it does not seem that it is about to be snuffed out. But as in any polite society, it is important that President Mitterrand's visitors at Fontainebleau should not make fun of him for his enthusiasm or, worse, suppose that he was not serious (which in some sense may nevertheless be true). The British among Europeans are notoriously given to the practice of a maddening pragmatism, and are at risk of forgetting that if

President Mitterrand were only half serious, he may nevertheless have hit on a way that will appeal to others of circumventing present impediments in Europe. The best hope at Fontainebleau is that both the British and their detractors will find some way of bridging the gap between short and long-term interests. The best field in which to look for a bridging formula is that for wringing from Europe's academic and research institutions the promise of which they are richly capable. □

One treaty to sign

One or other of the nuclear powers should urge that the threshold test-ban treaty be ratified.

ON the face of things, there seems no prospect of an early improvement in relations between the Soviet Union and the West. Even the proposal that the president of the US National Academy of Sciences, Dr Frank Press, should go to Moscow to try out some unspecified plans for further collaboration has been put off by accumulating doubts about the welfare of the Sakharovs (see p.485). This week's economic summit in London, which has brought together many of those who might have been able to influence events, was constructed around a different agenda (and a pretty empty one at that). Next will come the Northern Hemisphere's vacations and then the presidential election campaign in the United States, into which President Reagan will plunge without the once-hoped-for deal with the Soviet Union on some form of arms control. On present form, it will be a full year before anybody who matters will be in a frame of mind to take constructive steps.

Here, then, is a simple recipe for action now, not sometime in the future: dust off the Threshold Test-Ban Treaty and see that it is ratified by the United States and the Soviet Union. The treaty has been signed for the past decade, since when both the major nuclear powers have publicly insisted that they have kept to the letter of the treaty, which forbids the testing of weapons yielding more than the equivalent of 150,000 tons of conventional explosive. (Because of the earlier partial test-ban treaty, such tests must of course be underground.) While there have been complaints in the past few years, especially from the United States, that the treaty has been violated, the seismic evidence on this point is inconclusive or, more accurately, is consistent with the view that both the major powers have kept their unratified bargain with each other and the rest of us.

So why bother to ratify the treaty, in the process running the risk of a refusal by the US Congress? There are several practical reasons, not the least of which is that the full text of the treaty includes provisions for the exchange of seismic data about the neighbourhood of known testing sites that make the remote monitoring of other people's nuclear explosions less ambiguous, perhaps much more precise. It seems strange that neither of the major powers has sought to reap these benefits — or to shame the other by provoking a public declaration of unwillingness to ratify an otherwise agreed document. That, however, is only one of a long list of reasons why reasonable powers should legally endorse a reasonable document.

The threshold treaty may be a pale shadow of, say, an agreement on European missiles or a further instalment of the strategic arms agreements, but it has been negotiated and the others have not. And while it may not obviously be the "substantial" step towards strategic arms control required of the nuclear powers by the non-proliferation treaty, it is much more than the nothing that, on present form, the nuclear powers will have to report to next year's review conference of that treaty. Finally, the threshold treaty offers obvious scope for extension — reductions of the threshold, remote but on-site inspection — that could help to provide later and more ambitious agreements. It should not have escaped the US Administration's notice that a ratified agreement would also give the president something to boast about in November. The trouble is that there is very little time to act, with the party conventions in the United States only weeks away. That is another argument for moving quickly. □

Shoestring research

The problems of British research are epitomized by this week's closure of a laboratory.

WHILE nobody is conspicuously to blame that one of the best-known British laboratories in the neurosciences is to be closed (see p.486), the affair should give pause to those responsible for the management of research in countries such as Britiain, but in Britain in particular. And while the Medical Research Council (MRC) is on this occasion lucklessly responsible, there is every reason to expect the laboratories under the wings of other organizations will similarly find themselves in trouble when the time comes to replace a director who has decided (for good personal reasons) to quit. What has happened is a depressing symptom of what is wrong with the condition of British science.

The MRC Neurochemical Pharmacology Unit has its origins in the council's general policy, going back to before the Second World War, that research can be powerfully stimulated in important fields by providing a scientist of distinction with a good laboratory and a team of close colleagues with whom he can expect to work for decades to come. Of necessity, these units are small and also impermanent. If the good scientist should die, retire or simply quit, the case for the perpetuation of the unit may disappear at the same time. Ironically, the Cambridge unit partly owes its existence to the disappointment caused twenty years ago by the departure for the United States of the then newly appointed head of a similar initiative at the University of Birmingham. On this occasion, the council seems sensibly to have decided that the work of its unit at Cambridge was important enough to justify the search for a successor to the departed director. The outcome, by all accounts, has been disappointing. Part of the trouble seems to have been the search committee's confusion about its objectives. Should it seek a more or less classical pharmacologist? An up-to-date neuroanatomist? Or a molecular biologist? The difficulties seem to have been aggravated by some candidates' agony in making up their minds and by other people's choosiness about candidates with whom they would or would not work. In the event, the mere passage of time seems to have put paid to the hope that the unit could be kept alive.

Recriminations will now abound, but are inappropriate. To spend more than two years looking for a suitable person and then to fail to find one may betoken indecisiveness but is more vividly a proof that Britain, even Cambridge, is no longer a kind of mecca for professional people from elsewhere. Those who think otherwise might reflect on the recent fall in the value of the pound sterling (at or below $1.40), but there are more serious difficulties. A unit of a dozen or so people may be able to make an important mark in some chosen field if it has been welded together by some central instigator, but is otherwise probably too small to be able to hold its own against the competition. An attempt to create in Britain a unit on a scale that would be capable of holding its own in the exciting but competitive game of telling which genes do what in neurones would be doomed to failure now that speed in working out the nucleotide sequence of a gene has apparently became crucial. The particular lesson for MRC is a further narrowing of the scope for setting up research units on the now-familiar pattern. And just as the Science and Engineering Research Council is being forced by circumstances to reconsider its role in the support of high-energy physics, so MRC may soon find that some fields of once-cheap research are beyond its means.

The other lesson, for British research managers of all kinds, is the importance of flexibility. Historically, MRC's units have been successful because it has been possible to found them quickly in emerging fields of interest, and without uprooting people in the process. There will no doubt continue to be scope for entrepreneurship of that kind. But if competitiveness is important, there can be no preordained pattern or scale for the operation of such units. Those which succeed must be encouraged to grow, even in directions not foreseen. Others, less successful than the Cambridge laboratory, must be allowed to lapse. Doing nothing is the worst policy. □

US genetic regulations

Bacterial field trial to go ahead

Washington

TWO weeks after a federal judge halted Dr Steven Lindow's planned field trial of recombinant ice-nucleating bacteria (see *Nature* 24 May, p.296), the Recombinant DNA Advisory Committee (RAC) of the US National Institutes of Health (NIH) approved a virtually identical proposal from Advanced Genetic Sciences Inc. (AGS), at its meeting on 1 June.

The Lindow experiment was blocked by Judge John Sirica in response to a motion for a preliminary injunction filed by anti-genetic-engineering activist Jeremy Rifkin. The judge's ruling also barred RAC from approving any other experiments involving release of recombinant organisms to the environment until a full hearing can be held on Rifkin's claim that RAC must prepare an environmental impact statement before proceeding in this area. According to NIH officials, preparation of such a statement would require at least a year. (On 25 May, the Court of Appeals in Washington upheld Sirica's preliminary injunction against the Lindow experiment.)

Sirica's decision specifically exempted commercial proposals, however, which are not in any case legally bound by RAC decisions, although companies have been submitting proposals to RAC for review in keeping with the standard practice of voluntary compliance with the RAC guidelines.

At last Friday's meeting, Rifkin asked the committee not to establish a "double standard" that would give private companies an unfair advantage over federally-supported research, which is legally bound by RAC decisions. Robert Mitchell, chairman of the committee, responded that he had ruled that RAC would continue to consider commercial proposals, noting that they were specifically exempted from the court's decisions, which in any case applied only to NIH administration, not the RAC itself, which is legally an advisory body to NIH.

RAC took noticeably greater care this time to spell out its reasons for believing that the ice-nucleating experiments do not pose a risk to the environment. Dr Anne Vidaver, a plant pathologist from the University of Nebraska and a consultant on both the Lindow and the AGS proposals, noted that the modified bacteria to be used in the trials — so-called INA–, for ice-nucleating activity minus — already exists in nature along with the INA+. The INA– are lacking a gene responsible for the ice-nucleating protein, a protein believed to mediate frost damage to plants at temperatures a few degrees below freezing. Vidaver said that in natural populations of the bacteria (a variety of *Pseudomonas syringae*) as much as 80 per cent may be INA–. She said that apparently the only reason for using recombinant DNA techniques for producing the INA–, rather than simply culturing naturally-occurring ones, is that natural organisms are not patentable.

Vidaver recommended several modifications in the AGS proposal: an increase in the frequency of monitoring of the field plot, the withholding of approval of continuing experiments involving other, unspecified varieties of INA– *P. syringae* and a limit of the tests initially to one growing season, rather than the three requested. If preliminary data show no problems, she said, approval for additional tests should be given at that time.

At its 1 June meeting, the committee also approved a proposal from Cetus Madison for testing an undisclosed plant variety (the decision was made at a closed session of the committee) and adopted a set of "points to consider" for researchers preparing future proposals for plant field trials. The committee noted that past submissions have often been complete, necessitating their return for additional information. The list of points calls for proposals to include details on specific cultivars, vectors (including documentation that the vectors will not acquire pathogenic potential), data from greenhouse studies and monitoring procedures.

The committee also approved lowering containment of a previously approved toxin-cloning experiment from P4 to P3, or to P2 if the clones prove to be of low toxicity. The proposal, submitted by Dr Alison O'Brien of the Uniformed Services University of the Health Sciences, a part of the Department of Defense, involves cloning a shigella-like toxin in *E. coli*. The aim is the development of a vaccine against dysentery.

Stephen Budiansky

Telecommunications

Luxembourg goes for cable

TINY Luxembourg has thrown a spanner into the comfortable world of European telecommunications. In particular, Luxembourg has deeply offended the government of France by announcing that it plans to license a commercial consortium to launch communications satellites capable of delivering television broadcasts to cable networks throughout Europe.

Among European governments, France is the most deeply offended because France has been relying on Radio-Tele-Luxembourg, the commercial radio and television company based in Luxembourg, to pay towards the cost of the direct broadcasting satellites which France plans to launch in the next few years. Although Luxembourg, like other members of the International Telecommunications Union, has been allotted space in geosynchronous orbit for satellites capable of broadcasting signals powerful enough to reach individual receivers, the Grand Duchy appears for the present not to plan to take up this option.

Instead, the government of Luxembourg is planning to license the Société Luxembourgeoise des Satellites (SLS) to launch less powerful telecommunications satellites. The company, whose chairman is Mr Corneille Bruck, the president of the state savings bank of Luxembourg, will eventually operate under the name of Coronet.

For Luxembourg, which relies on Radio-Tele-Luxembourg for a substantial fraction of its revenue, the development is something of a surprise. While some observers consider that the move spells an end to the cosy relationship, some say identity, between the government and Radio-Tele-Luxembourg, others consider that the government may simply be insuring against the chance that direct broadcasting satellites will be unprofitable.

French uneasiness about the new plan seems to centre on the threat it poses to the commercial viability of the French direct broadcasting satellites. There is also some uneasiness within the European Telecommunications Satellite Organization (EUTELSAT), the European equivalent of INTELSAT. A meeting of the organization, on which national telecommunications authorities, mostly nationalized, are represented, held in Paris towards the end of May, shrank from condemning Luxembourg for a divisive move and instead urged on all its members the need not to take part in competitive international telecommunications services. Luxembourg insists that the plan for Coronet, aimed at delivering broadcast signals only to the operators of cable networks, escapes that criticism and so should be free from constraint.

However this may be, the row between Luxembourg and its larger neighbours has vividly drawn attention to three points. First, Luxembourg is determined to remain a principal exporter of broadcast signals even in the new technological age. Second, national susceptibilities as to who should be free to broadcast to whom are as fierce as they have ever been. Third, the commercial future of direct broadcasting satellites, capable of reaching individual homes, seems to be clouded by Coronet's demonstration that low-powered satellites coupled to cable systems can be built quickly and cheaply. □

Soviet jurisprudence

Nature letter heading for trial

New York

A LETTER from ten Moscow scientists published on *Nature*'s correspondence pages in December 1981 (**294**, 688; 1981) may be cited as nominal defendant in a prosecution under Article 190/1 of the Russian Republic's criminal code, according to a recent Western visitor to Moscow. During the past two years, the signatories remaining in the Soviet Union (two have been allowed to emigrate) have on several occasions been called into the procurator's offices as "witnesses" against the letter. Formally the case is still pending — but the visitor met separately two of the signatories and members of their families all of whom said that pressure was mounting and they feared that formal proceedings might start soon. The plight of one signatory, Dr I.S. Irlin, is referred to in Correspondence (p.490).

The letter drew attention to the signatories' "hard and humiliating" plight since they had filed applications to emigrate to Israel. "Almost all of us have lost our jobs", they wrote, "and we are denied any possibility of continuing with our scientific research. The doors of scientific institutions, laboratories, seminars, conferences and symposia, editorial offices and publishing houses are shut in our faces. We are being deprived of our scientific degrees . . . We have in fact been thrown out of society, but at the same time are not allowed to leave the Soviet Union."

One of several lines adopted by the Soviet interrogators was the legal fiction that the letter might be a forgery. They accordingly demanded that the signatories give evidence on this point. So far, it appears that all have refused either to confirm or deny the authenticity of their signatures.

The rationale behind the odd piece of jurisprudence of accusing the letter itself and not the signatories is simple — in Soviet law, accused persons have the right to stay mute, but witnesses have no such privileges. Already on at least one occasion, the ploy of "prosecuting" a document has been used. Dr Viktor Brailovskii, the mathematician who for many years hosted the unofficial Sunday seminars for refusniks and who has just completed a term of Siberian exile under Article 190/1, was originally called as a witness against the *samizdat* journal *Jews in the USSR*, which he edited. During the case new charges were framed against him, and he ended up first in the dock and then in Siberia.

The same ploy may therefore be expected against one or more of the eight remaining signatories (L.A. Dikii, M.I. Freidlin, I.S. Irlin, A.L. Vasilevsky, M.I. Reitman, S.A. Katz, Ya V. Medvedkov and V.N. Soyfer). The prosecution is clearly keen to get its evidence. The wife of one of the signatories has reported that she has been repeatedly approached by a "friendly" KGB man who urged her that it would be "best" for her husband to testify.

Events seem to follow closely on the trial of Brailovskii. The letter in *Nature* and the accompanying leading article are well known in the Soviet Union. In the circumstances, it seems strange that news of a possible case touching on editorial policy should reach the editor only through the unofficial channel of a returning academic visitor. **Vera Rich**

Soviet Jewry

Refusnik flow slows to trickle

Jerusalem

DR Yoram Dinstein, rector of Tel Aviv University, last week announced a new endowment fund to establish university posts for Jewish scientists emigrating from the Soviet Union. The timing was somewhat inauspicious. Israeli universities are so short of funds that six months ago it was feared that the entire higher education system might have to close down altogether. Even now, no vacant posts can be filled, and all non-tenured academics are under threat of redundancy. Positive discrimination in favour of new arrivals from the Soviet Union could be a major cause of friction.

The endowment fund has been set up by Mr Fabian Kolker of Baltimore, Maryland, a governor of the university, as part of his overall strategy to halt the problem of the *nashrim* — Soviet Jews who emigrate on a visa for Israel but who then settle elsewhere, usually in the United States. But the rules of the fund allow the annual interest to be used to help Israeli scientists seeking academic posts should there be no suitable new immigrants from the Soviet Union.

Although Jewish emigration from the Soviet Union is now down to around 50 a month (from a regular 3,500 a month in the early 1970s and a freak 4,500 a month in 1979), the fund has already been used to create a post for one recent arrival, Dr Grigorii Freiman, a mathematician. But under present circumstances it may be some time before another Soviet candidate arrives.

The clampdown on emigration has focused attention once again on the estimated 300 Soviet Jewish scientists who have already filed visa applications but who have been refused permission to leave. Deprived of their scientific posts, "overqualified" and therefore unemployable in other jobs, refusniks are now liable under new Soviet legislation to arrest for "parasitism" if they are without visible means of support for more than two months.

Since 1964, refusniks have sought to keep up their scientific work through unofficial seminars and even international conferences, the first of which was totally frustrated — the Soviet would-be participants were temporarily deported from Moscow and invited foreign participants denied visas. Last week, an anniversary conference was held at Tel Aviv University (also on the initiative of Mr Kolker), with scientific papers presented by, among others, Professor B. Pippard, Professor E. Segre, Professor P. Kessler, Professor H. Markovich and the Israeli Minister of Science, Professor Yuval Ne'eman. Former refusniks taking part included Professor Benjamin Levich (a Corresponding Member of the Soviet Academy of Sciences), Dr Eytan Finkelstein, Professor Alexander Voronel who founded the refusnik seminars and Professor Mark Nobel, who succeeded him as convener.

A number of papers by present refusniks were read *in absentia*. The principal aim of such gatherings (including previous conferences in the United States and Stockholm) is to present the refusniks' work in its scientific content and to demonstrate that the seminars (which still continue in Moscow and elsewhere, albeit somewhat less regularly than previously) can generate meaningful work.

The question arises, however, whether such special meetings are the only or the best way of presenting the refusniks' work. Invitations to international conferences abroad are, of course, only symbolic gestures, while conference programmes are now too crowded to permit the custom of the 1960s of keeping blank the time-slot allotted to a Soviet participant who fails to arrive. Even papers sent to be read *in absentia* will usually be crowded out.

One approach not apparently tried so far is to encourage refusniks to submit contributions for poster sessions. Many of the papers at the Tel Aviv conference were, in fact, of poster length, having been dictated by telephone.

With a scientific colleague abroad as sponsor, such participation could prove a valuable way of keeping the refusniks in the world scientific community. **Vera Rich**

Sakharov

US academy cancels visit

Washington

MOUNTING anxieties about the healthof Dr Andrei Sakharov and his wife Yelena Bonner have forced the US National Academy of Sciences to postpone a planned visit to the Soviet Union next week. Dr Frank Press, president of the National Academy of Sciences, announced last month that he planned to deliver new proposals for resuming formal research links with the Soviet Academy of Sciences. The US academy decided to suspend the links in 1980 as a protest against a Soviet Government decision to condemn Dr Sakharov to internal exile in the town of Gor'kii, some 250 miles east of Moscow.

An academy spokesman said the visit was now in abeyance but the condition of the Sakharovs was being monitored daily. In a telegram sent jointly with the Royal Society of London, the Academie des Sciences de L'Institut de France and the Royal Swedish Academy of Sciences, the US academy at the end of May called on its Soviet counterpart to "act as effectively as possible to help Academician Sakharov and his wife in getting the health care they require and request".

The sudden crisis over the Sakharovs could hardly have come at a worse time for the academy, which had already come under criticism from some quarters for its decision to seek a resumption of ties with the Soviet academy. In an interview on 23 May, for example, Dr George Keyworth, President Reagan's science adviser, said he was "rather surprised" by the decision.

Dr Press has consistently refused to provide details of the proposals he would be taking to Moscow, but apparently hopes to revive the relationships that existed 20 years ago, when distinguished scientists from both countries took part in exchange programmes. Since the US and Soviet academies established a formal exchange programme 25 years ago, 500 scientists have travelled in each direction, but the volume of exchanges dwindled after the US academy declared a moratorium over the Sakharov affair. During 1983, there were a few individual exchanges; 26 Americans visited the Soviet Union for a total of 38 months while 13 Soviet scientists spent a total of 31 months in the United States.

Reaching a new agreement with the Soviet Union may prove difficult even if the political controversy surrounding the Sakharovs abates. Although the US academy is keen to resume links, it wants to change the way Soviet scientists are selected for visits to the United States. US scientists have often complained that under previous exchange agreements, too many junior scientists were being selected by the Soviet Union for visits to the United States.

Star wars

Sceptical report from OTA

Washington

THE Reagan Administration has responded with unusual ferocity to a report by Congress's Office of Technology Assessment (OTA) that casts doubt on the ability of the United States to build a space-based "star wars" defence against nuclear attack. Lieutenant General James Abrahamson, former shuttle director and newly-appointed head of the star wars initiative, has told Congress that the report contains "technical errors, unsubstantiated assumptions and conclusions that are inconsistent with the body of the report".

The OTA study, published at the end of April, is the only detailed technical analysis of the star wars idea yet to be published by a neutral government body with full access to classified research data. Its author, Dr Ashton Carter of the Massachusetts Institute of Technology, concluded that the prospect of being able to develop a "near-perfect" defence against nuclear missiles was so remote that it should not form the basis of public policy.

Although they cleared the report for publication, a number of high-ranking defence officials have complained privately that it contained sensitive details of progress in research that should not have been disclosed. A Republican congressman, Henry Hyde of Illinois, has threatened to launch an enquiry into OTA's "alleged security breaches" and to propose legislation making semi-autonomous bodies like OTA "more accountable" in handling sensitive information.

OTA, however, dismisses the allegations of a possible breach of security. Dr Carter, a former DOD analyst specializing in anti-ballistic missile systems, maintains that the report discloses next to nothing about the current state of US research on any of the sensitive technologies. And in a point-by-point rebuttal of General Abrahamson's technical criticisms, OTA insisted last week that its report was technically correct.

Because they are hamstrung by secrecy requirements, neither side in the debate has been able to substantiate its technical criticisms and rebuttals. Much of General Abrahamson's report, for example, consists of simple assertions that OTA based its conclusions on outdated information and was therefore too pessimistic. In response, OTA has been able to say only that it is familiar with all the latest work and that its conclusions are fair.

One of the main technical quarrels is about the use of new fast-burn missiles which, OTA believes, might thwart a star wars defence because their rockets would burn out while they were still in the Earth's atmosphere. The administration's initiative stresses the importance of intercepting missiles during their boost phase, while they can be easily detected by their exhaust plume and before they deploy their multiple warheads. Fast-burn boosters would be vulnerable for a much shorter time and the atmosphere would help to shield them from several futuristic weapons such as neutral particle beams and X-rays.

General Abrahamson, however, rejects OTA's view that the deployment of such boosters by the Soviet Union could prove a "potent, even decisive" countermeasure against directed energy weapons. It would, he says, take many years and a lot of money for the Soviet Union to deploy a large fraction of its arsenal on such boosters. Even then, their use would reduce the payload and accuracy of their missiles by between 70 and 90 per cent. OTA counters that "nothing like" a reduction of that magnitude would be necessary; it believes fast-burn boosters could be designed to deploy heavy payloads accurately enough to destroy US missile silos, and certainly cities.

OTA and DOD also disagree about how well lasers, X-rays and particle beams could perform as star weapons. General Abrahamson says OTA underestimates the effective range of chemical lasers and disregards promising (but secret) progress in the range of X-ray lasers and neutral particle beams and their ability to penetrate the atmosphere. According to the general, new advances enable a "modest" constellation of beam weapons to "negate most ballistic missile threats". And he dismisses OTA's argument that satellite battle stations and the other space-based paraphernalia of a star wars system would be extremely vulnerable to attack; he says a number of effective means have been developed to ensure that satellites could survive an attack.

General Abrahamson's response to OTA may well have been unusually sharp because it was published before it could be reviewed by the national laboratories most closely involved with star wars research. In subsequent reviews, the general claims, experts at the laboratories found the report full of technical flaws. Even this claim, however, is in dispute; Dr Carter says many scientists at the laboratories support OTA's conclusions.

Whatever its merits or defects, the report has made its mark in Congress. The House of Representatives' subcommittee on international security and scientific affairs cited it in a critical report last month on the administration's space arms control policy. The report said Congress had received no "conclusive" evidence that a perfect or near-perfect defence is technically feasible. It added: "As has been the practice between the superpowers in the nuclear age, the practice of each side developing a countermeasure to the other side's systems could continue unabated under the US and Soviet strategic defence programmes."

UK medical research

Neurochemical unit threatened

ONLY a few months after advertising its intention to spend more on research in the neurosciences, the British Medical Research Council (MRC) is taking steps to close one of its better-known units in the field, the MRC Neurochemical Pharmacology Unit at Cambridge. The decision, made known to the staff last week, comes two and a half years after the then director of the unit, Dr L.L. Iversen, announced his appointment as director of a new research laboratory established by Merck, Sharp and Dohme at Hoddesdon in Hertfordshire.

MRC's decision, described as a "decision in principle", will be controversial. The unit has in the past twenty years acquired a reputation for the development and understanding of neuroleptic drugs, chiefly by the refined application of classical pharmacological techniques. More recently, the unit has taken an interest in the histological examination of post-mortem brains, especially from people with schizophrenia.

The unit, one of several maintained by MRC, usually in close association with a university, consists of a score of people of whom perhaps a dozen are established scientists. In its heyday, the unit also played host to large numbers of postdoctoral fellows from elsewhere. The budget for the current year is £375,000.

There is some confusion about the reasons given for closing the unit, said last week to have been made necessary by the difficulty of recruiting a suitable successor to Iversen, at least within the limits of what the council had been prepared to pay for the job. The council said earlier this week that the post had been widely advertised and that the salary offered had been the equivalent of that of a university professor.

On the other hand, Dr Leslie Iversen, the previous director of the Cambridge unit, said that he was "furious" at MRC's decision in principle that the unit should be closed. He said that he had only recently been consulted about at least one eminently suitable candidate who had been interested in the job. He said he planned to write in protest to the secretary of the council, Sir James Gowans, saying that the appointment of his successor had been mishandled and that he doubted whether the council would be able to economize by closing the unit, given that many of the members of the unit were tenured members of the council's staff and that the space vacated by the dispersal of the unit would quickly be occupied by others.

Another factor in the council's decision seems, however, to have been the British Government's refusal of its request for extra funds to sustain an expansion of research in the neurosciences. The council is understood to consider that with recent developments at Imperial College, London, Oxford, Edinburgh and Newcastle, it has done as much as could be expected to strengthen the pattern of British research in this field.

A further difficulty seems to have been the changing composition and objectives of the search committee, which at various times seems to have been anxious to confirm the previous pattern of research in the Cambridge unit and at others to wish to branch out in new directions. The search seems to have been in abeyance for a full six months early in the proceedings, when one candidate to whom the job was offered found it hard to make up his mind.

On other occasions, the committee seems inexplicably to have tried to tempt distinguished researchers from the United States with inadequate rewards. The salary offered was formally stated this week to be the equivalent of that of a university professor although it is known that at least to one candidate from overseas figures in the neighbourhood of £30,000 a year were mentioned and not scorned.

The immediate future of the rump of the Cambridge unit is far from clear. The next step is that a management committee of council scientists will visit Cambridge to hear what plans the remaining scientists may have and eventually to make recommendations to the council.

Dr P.C. Emson said from Cambridge earlier this week that interest among potential postdoctoral fellows in work at the Cambridge laboratory had sharply declined in the past six months. He also said that MRC had only a few months ago given the unit the right to fill a research studentship from the beginning of the coming academic year but had then "taken it away again last week".

Even at this late stage, it seems that at least part of the rump could be reprieved. One possibility that has been suggested is that the remaining members of the unit might be able successfully to persuade MRC to support them with a five-year project grant. Most observers, however, consider that those concerned will quickly be tempted to take posts elsewhere.

John Maddox

High-energy physics

UK debate goes public

THE Kendrew committee set up to review British participation in Europe's high-energy particle physics has now asked members of the research community for their views. The group particularly wants opinions about the relevance and standing of the current UK effort, technical and educational spin-off and of any problems of the European Organization for Nuclear Research (CERN).

Others besides particle physicists may feel moved to respond: the review group will also be pleased to hear about other new areas of science, or grossly underfunded existing areas, that would benefit from a significant increase in support.

The review, under the chairmanship of Sir John Kendrew, was set in motion earlier this year at the instigation of the Advisory Board for the Research Councils, which is studying the question jointly with the Science and Engineering Research Council (SERC). The council expects to spend £52.6 million on high-energy particle physics in 1984–85; £35.6 million of this is the UK subscription to CERN, while most of the remainder relates indirectly to work at CERN. Strong competing claims on the science budget led to questions about whether the high cost — almost one fifth of SERC's expenditure — was justified.

The committee expects to complete its onerous task within a year, and is planning a hectic programme of activity. Apart from the obligatory visit to CERN in Geneva, it will visit other countries to see how their ideas compare with those in Britain. Germany and the United States are provisionally scheduled for visits, and the committee will also visit British laboratories that work in particle physics.

Legal advice has been sought on the question of Britain's contractual obligations to CERN. It seems to be recognized that Britain could legally withdraw from CERN with one or two years' notice, although the political backlash would be severe. One view is that Britain is morally committed to CERN at least until the completion of LEP 1, the electron-positron collider now under construction and scheduled to start operations in 1987–88.

If, as seems possible, this view is accepted by a majority of the committee, the issues will centre on what should come after LEP. One possibility the committee hopes to look at is that of greater collaboration with the United States — although there are doubts about whether US scientists would be happy to forgo a machine based in the United States for one in Europe.

Speaking at last week's meeting of the American Association for the Advancement of Science, CERN's director general Dr Herwig Schopper suggested that the LEP tunnel could form the basis of a future proton machine with capabilities similar to those of the planned superconducting Super Collider (SSC) but at a much lower cost. The continuing uncertainty over US commitment to the SSC may make it hard for the Kendrew committee to come to any firm conclusions.

Tim Beardsley

Submissions to the review group should be sent to: Dr Keith Root, Room 5/37, Department of Education and Science, Elizabeth House, York Road, London SE1 7PH.

US research grants

New pork-barrel row breaks

Washington

A YEAR of tireless campaigning by university leaders in the United States has failed to keep "pork barrel" politics out of the 1985 science budget. Georgetown University in Washington DC is asking Congress to direct the Department of Defense (DOD) to support a $220 million energy demonstration project at the university without going through the usual peer review procedures.

The timing of Georgetown's initiative has horrified the scientific community in Washington, which has spent much of the year trying to persuade Congress that research funds should be distributed according to scientific merit determined by peer review. The campaign began last year when two universities, Catholic University in Washington DC and Columbia University in New York, employed a Washington-based lobbying firm to talk Congress into earmarking last-minute funds for scientific facilities at their institutions, although there had been no peer review in either case.

Those developments provoked a stream of resolutions and statements by scientific and university bodies stressing the importance of peer review. Since then, virtually every university spokeman testifying before committees on Capitol Hill has included a statement explaining that wise scientific investment requires that proposals should be assessed on their merits.

Last month, nevertheless, Georgetown's lobbyist, the Reverend Byron Collins, appeared before the House appropriations subcommittee on defence to request $9 million in 1985 to start work on the university's unsolicited proposal for a coal-gasification and fuel-cell cogeneration programme. The committee's first response has been favourable; last year, it agreed to a Georgetown request to convert $820,000 of army research funds to planning the project.

Two higher education associations, the Association of American Universities and the National Association of State Universities and Land Grant Colleges, are spearheading a drive to block the Georgetown project. A staff paper circulating within the associations accuses Georgetown of consistent attempts to use its political clout to win research funds. "Over many years", the document says, "the university has taken great advantage of its location to cultivate key members of the Congress and to gain their support for legislation granting the university special treatment . . . Georgetown initiatives are almost uniformly designed to circumvent the established competitive merit-based system for the award of university program funding".

Peter David

Animal legislation

California pounds stay open

Los Angeles

CALIFORNIAN researchers won a major victory last week in their continuing battle with antivivisectionists. A proposed measure to prohibit the use of impounded stray animals in experiments was defeated by 9 votes to 4 in a state assembly committee after intensive lobbying by a coalition of Californian universities and biomedical organizations. The bill, sponsored by state Senator David Roberti of Los Angeles, passed the California senate last year by a healthy margin. It would have prevented animal pounds in California from selling or giving away animals for research and would also have prohibited the transfer of research animals from one state to another.

The bill's defeat is now being interpreted as a major coup for medical researchers throughout the United States. Animal rights groups believe that if such a law had been passed in California, few states would have failed to follow. Nine have already enacted laws that forbid impounded animals from going to research laboratories but researchers in eight of these are allowed to import animals from other states. Only Massachusetts, which passed its animal protection bill several months ago, intends to forbid importation, and as a consequence it is estimated that the costs of experiments using dogs and cats will increase tenfold.

In their successful lobby against the bill, California researchers argued that it would have cost $12 million to establish breeding facilities for dogs and cats and some $8.5 million a year to run them. They noted that about 15.5 million unclaimed animals are killed in California's pounds each year, and that they take only 3 per cent of such animals to laboratories for experiments.

Senator Roberti seems to accept that the bill is dead. He says that he will recommend to humane groups that "the avenue available to them to change the hearts and minds of the legislature is to appeal directly to the people". Senator Roberti said he was not against animal research but, rather, against experiments on pets. But an alternative bill that would prevent pounds from turning "proven" pets over to researchers is languishing in the state senate because few people think it is enforceable.

Meanwhile, animal protection groups in California are livid. "The power of the University of California is overwhelming", said Gretchen Wyler of the Fund for Animals. "They are in control of this state." The next step, she said, will be to go to Washington DC to try to enact federal legislation.

The lobbying success of university and biomedical groups in California was extraordinary. Every major California newspaper supported them, while heart transplant recipients and blind diabetics pleaded before elected officials for continued animal research. Even so, the agony of the decision was clear. Committee chairman Richard Alatorre, as he cast his vote, said that a recent television programme on animal research had been a clear indictment of the academic community and of its conduct of research; but, he said, a good friend who died of leukaemia had begged him to vote for continued research on animals.

Sandra Blakeslee

Raid on US baboon laboratory

A GROUP calling itself the Animal Liberation Front has broken into a laboratory at the University of Pennsylvania, vandalizing equipment worth thousands of dollars and stealing 20 videotapes of experiments on baboons.

The laboratory, directed by Dr Thomas Gennarelli, has conducted experiments with baboons designed to simulate traumatic head injuries to people as part of the university's head injury research programme supported by a $1 million grant from the National Institute of Neurological and Communicative Disorders and Stroke.

A spokesman for the burglars, who have been identified only as "five members of the Animal Liberation Front", said that Gennarelli's laboratory was chosen for the break-in because his experiments are "notorious" and because of rumours that he had been filming them. Copies of selected tapes provided to local television stations by the burglars show the researchers making jokes about brain-damaged monkeys, and have provoked predictably hostile public reaction.

Dr Thomas Langfitt, principal investigator of the research programme, defended the as humane and vital for the improvement of the treatment for head injuries. The injuries are induced by accelerating the baboons' heads, without impact. Langfitt said the research has already revealed the mechanism by which damage occurs in such accidents; results have lead to mathematical and physical models of the axons and blood vessels in the brain during injury and to the design of improved crash helmets. Langfitt said that the baboons are tranquillized and lightly anaesthetized during the procedure. All the animals are eventually destroyed.

The Animal Liberation Front says it will turn over to the US Department of Agriculture evidence of violations of the Animal Welfare Act. The act requires the proper care and housing of animals, but leaves experimental design entirely up to the researcher.

Stephen Budiansky

Forestry

Taxing changes in prospect

POLICY proposals published this week by Britain's Forestry Commission include for the first time special provisions for the protection of Britain's ancient semi-natural woodland. In a consultative paper, *Broadleaves in Britain*, the commission suggests measures to minimize loss of all broadleaved woods and introduces guidelines agreed with the Nature Conservancy Council (NCC) for managing ancient semi-natural woodland. This change of heart by the commission, which previously failed to recognize this category at all, is seen as a major concession to conservation interests.

According to a survey (as yet incomplete) by NCC, losses of ancient semi-natural woodland over the past 40–80 years in different counties range from 10 per cent to over 60 per cent, with most counties so far surveyed showing losses of over 40 per cent. The commission, which advises private foresters and manages its own forests, now recognizes a good case for slowing the rate of future loss, and proposes new management guidelines that will automatically check felling proposals and grant applications against the NCC register of ancient woodland. For woods so categorized there will be "a presumption in favour of maintaining the species already present" and owners will be persuaded to adopt methods of working that are "least disruptive of the woodland habitat". Broadleaved woodland in general should be maintained at about its present extent by requiring replanting with broadleaves after felling and allowing permanent clearing "only exceptionally".

The Forestry Commission has been under intense pressure from conservation groups to change its policies in this area, and has consulted extensively with interested parties for more than two years. There was therefore some surprise this week that the new document is consultative and not a definitive policy statement. Comments can be made on the proposals even at this stage. The commission hopes nevertheless to offer its final advice to government before the end of the year, as proposed tax changes and higher grants for establishing broadleaved woodlands will need ministerial approval.

Most of the broadleaved woodland in Britain is in private hands. Timber Growers UK Ltd, which represents foresters' interests, welcomes the Forestry Commission's proposals as a big step in the right direction. But, in the view of the association's chief executive, Mr Ronnie Williams, the commission could have been much firmer. Private foresters are keenly aware of the need to improve financial provisions for owners of broadleaved woodland, who are at a disadvantage compared with owners of the faster-growing and more profitable conifer stands. The Forestry Commission now proposes to make it much easier for owners of mixed estates to claim tax relief on slow growing broadleaved plantations, a move welcomed by the timber growers. But, they say, the commission does not go far enough. Only by making broadleaved woodland management less of a financial burden in the hundred years or more from plantation to financial returns will the pressure to destroy ancient woodland be removed. It is also pointed out that the commission has hardly been providing a good example by its own planting policies: the vast majority of recent Forestry Commission plantations are of conifers.

The Forestry Commission makes much of the fact that the total area of broadleaves in Britain is now 15 per cent greater than in the 1940s, and its proposals could be briefly summed up by saying they aim to maintain the *status quo*. Private foresters, however, argue that a million acres of woodland were lost in two world wars and want a return to the levels of the turn of the century. But at present there are severe economic obstacles to broadleaved production, mainly the high costs of establishments, the low productivity and long rotations.

The Forestry Commission is currently reconsidering much of its research activity, and that on productivity of broadleaved species is one important area of discussion. The new *Broadleaves in Britain* document gives some indications of where it might be heading. The review group that produced the document considers it is "doubtful" whether improvements in growth rate can be achieved through the use of fertilizers, and in the long run the improvements will come about through genetics, most probably using vegetative propagation techniques and clonal testing. There is also, according to the group, a need for more information on total biomass production and how this is affected by spacing and harvesting regimes, as well as the properties of species mixtures and newly introduced species.

Tim Beardsley

European biotechnology

Optimism abated as summit looms

Brussels

OFFICIALS of the European Commission fear that the Community's proposed biotechnology programme is falling foul of the present crisis in the Community's affairs. One sign of this is that the powerful agricultural lobby is mobilizing to block certain reforms that would have helped the growth of a strong biotechnology industry.

In spite of the generally favourable reception of the proposed programme by both research and industry ministers in November and December last year, that conjunction of omens seems now to be dissipating. "The alliance is coming unstuck", complained one official, citing the objections now raised by the sugar beet industry to a new pricing regime for the industrial use of sugar. "The sugar beet industry thinks that the biotechnology programme is the thin end of a wedge" leading to lower prices which, the official guesses, is the reason why agricultural ministers are now dragging their feet.

The Commission, meanwhile, is trimming its optimism about biotechnology to the changing wind. Last year, the Commission asked for a five-year programme costing 200 million European Currency Units (ECU) (about £118 million) but in its revised proposal put forward on 26 April, the Commission asked for only 88 million ECU covering only two of six of the original proposals — research and training and "concertation" with other biotechnology programmes.

At this level, the programme would represent a little more than a million dollars per country per year, an order of magnitude less than the Esprit information technology programme. The Netherlands and Denmark are unhappy about the size of even this proposal, while the United Kingdom and West Germany want the programme cut back drastically. "The council seems intent on reducing the whole thing to ashes before they have to build the whole edifice again", said one frustrated scientist.

The cuts and delays are especially galling for officials still smarting from the criticism earlier this year from the US Office of Technology Assessment that Europeans are not aggressive in commercializing biotechnology and pose little threat to the US industries.

At the twice postponed meeting of science ministers, now fixed for 29 June, there is even a danger that discussion of biotechnology will be swamped by two other items of high importance — telecommunications and the fusion programme. A spokesman for Research Commissioner Etienne Davignon insists that biotechnology retains its high priority, but British officials complain that they have yet to see where it fits into the Commission's larger scheme of things.

A further imponderable is that, by the end of June, the next Community summit at Fontainebleau may or may not have resolved the Community's budgetary crisis. The Commission may decide to go for a decision in principle on biotechnology, letting the question of funds hang loose until later, but in any case the programme will have to await an opinion of the newly elected European Parliament, and so is not likely to see the light of day before next year. "But if things go badly at Fontainebleau", said one senior European official, "it could be a catastrophe for European research".

David Price

Federal laboratories

Packard calls for flexibility

New York

IMPORTANT changes in pay and conditions may be on the horizon for scientists employed in the United States' 700 federal laboratories, which include the National Insitutes of Health and laboratories run by the Departments of Energy, Defense and Agriculture. An interdepartmental committee headed by the White House science office has drafted legislation to free the laboratories from civil service pay regulations so that they can better compete with the universities and industry for talented scientists and engineers.

Addressing last week's meeting of the American Association for the Advancement of Science (AAAS), Mr David Packard, chairman of California's Hewlett-Packard Corporation, said the model legislation was proposed in a draft report to be submitted to President Reagan in July. But he predicted that the legislation would stir up considerable opposition from vested interests in the civil service.

Mr Packard, a personal friend of President Reagan, strongly criticized the civil service's inflexible procedures for pay and promotion in a review of the federal laboratories he conducted last year for the White House Science Council. The new legislation, he said, would create a separate personnel system for scientists and technicians, replace narrow pay bands with broad ones, waive the existing pay ceiling for senior employees and allow promotions to take account of merit as well as seniority.

The report going to President Reagan in July will claim there has already been impressive progress towards implementing other recommendations in last year's Packard report. In response to a call for clearer definitions of the missions of each of the national laboratories, for example, the Agricultural Research Service has for the first time drawn up long-term research plans for its institutions. And the Department of Energy has begun to make its laboratories produce five-year plans in which each institution must state its direction, role, expected changes and budgets.

But the director of the Oak Ridge National Laboratory, Dr Herman Postma, told AAAS that progress had been uneven. Both Congress and the Office of Management and Budget (OMB) continued to block a proposal to bring financial stability to the laboratories by setting rolling budgets for two or three years at a time. The Department of Energy, responding to Packard and earlier reports, had begun to give each laboratory an "exploratory budget" to be spent at its director's discretion, but the level was between half and one per cent of the laboratories' budgets instead of the 5 to 10 per cent recommended by Packard.

Peter David

Antarctic treaty

Minnows smell a rat

Tokyo

THE Antarctic Treaty Consultative Parties (ATCP) ended their secret deliberations in Tokyo on 31 May with the announcement that "good progress" had been made towards an agreement permitting the exploitation of Antarctic mineral resources. Representatives of nations that have no say in how Antarctica is to be carved up, as well as conservation groups that had come to Tokyo to monitor the meeting, took a less charitable view.

Of the sixteen members of the Antarctic Treaty, seven have territorial claims to huge areas of the continent which have been held in abeyance since the treaty was signed in 1959. Entry now is restricted to those who carry out a full programme of research in the Antarctic. Despite the very great cost of maintenance of bases and ice breakers capable of reaching them, both Brazil and India thought it worthwhile to join last year (see *Nature* **307**, 105; 1984).

Under discussion in Tokyo, at the Fifth Special Mineral Resources Meeting, was a plan put forward by New Zealand representative Chris Beeby. The meeting was surrounded by secrecy — despite repeated protests from the Netherlands, not even representatives of the fifteen nations that have signed the Antarctic Treaty but which do not carry out research there (the "Non-Consultative Group") were allowed to send observers. But copies of the original draft of the Beeby plan were circulated by conservation groups, and individual delegates were willing to discuss privately amendments made since the last meeting.

Essentially, the plan proposes that mineral exploitation be regulated by three types of institution. At the top is a central commission which will be the ultimate political body for the whole mineral regime, with membership restricted to the 16 ATCP members and to nations with definite plans for mineral exploitation. Next will come a scientific and advisory committee whose members will be appointed by the central commission, to provide "technical guidelines" including those for environmental protection. It will not, however, have any power to enforce these guidelines.

Real power will reside with "regulatory committees", one for each area of the Antarctic when a proposal is made for exploitation in that region. Each will contain representatives from the United States, the Soviet Union, four nations with territorial claims, the nation proposing mineral development and another nation nominated by it.

What this plan neatly achieves is an accommodation between those with territorial claims and nations that actually want to carry out mining operations in the Antarctic. Beeby speaks proudly of the great success that the Antarctic Treaty has achieved over the past twenty years in keeping international rivalries out of Antarctica. His plan is primarily concerned with maintaining this internationalist spirit while permitting mineral exploitation to take place.

But to the smaller nations the whole plan seems designed to keep power in the hands of the Antarctic Treaty members. Malaysia received overwhelming support from the last meeting of the non-aligned nations for a resolution calling for a UN debate on the Antarctic issue during 1984, a move that could end with a conference like that of the Law of the Sea which would call Antarctic resources, like ocean bed resources, the heritage of all mankind.

The non-aligned group accuses the treaty members of trying to tie up a minerals agreement to pre-empt such a move. Indeed, if environmental groups are right, preliminary investigations of Antarctic oil resources have already begun — despite a 1977 agreement to restrain exploration while "satisfactory progress" is being made towards a minerals agreement.

What disturbs the environmentalists more, however, is that there would be no publicly accessible central body with the power to ensure that the Antarctic environment is not damaged under the Beeby plan. To divide the Antarctic into regions, each under the control of an eight-nation group with an interest in exploitation, would, they claim, prevent any overall or consistent ecosystem management. And the Beeby plan contains no provision to regulate preliminary prospecting, even though a test drilling that went wrong could have appalling effects. There can be no guarantee that a nation will effectively discharge its obligation to supervise the mining operations of its nationals. Instead, the major conservation group concerned, the Antarctic and Southern Ocean coalition of 150 environmental organizations from 37 countries, is calling for an Antarctic Environmental Protection Agency to oversee all Antarctic operations. There is sympathy for this idea from some ATCP members, but not from the two superpowers.

That the Beeby plan has only been slightly modified since the last meeting of the Mineral Resources Group suggests that its form is close to being acceptable by the ATCP members and that the idea of an Environmental Protection Agency will stand little chance — although it is impossible to be sure, given the secrecy of the discussions. Discussions will continue in February 1985 with Brazil as the host country. There, for the first time, the non-consultative parties to the Antarctic Treaty will be allowed to send observers and it may be possible for more than a handful of nations to find out what is going to happen in Antarctica.

Alun Anderson

Pleas for would-be emigrés

SIR — We wish to draw your attention to the case of the respected Soviet cancer researcher, Dr Iosef Irlin, who has been involved in the fields of tumour virology and tumour immunology. His work has been of theoretical importance and in no way related to matters falling within any national security interests.

Dr Irlin applied four years ago for permission to emigrate with his family to Israel, to be reunited with other members of his family there, and he has reapplied repeatedly during the past four years. All his requests have been refused, without explanation. During this time, he has been without professional employment and his several applications for jobs have been rejected.

In an earlier letter, Dr Irlin states:

> It is now four years that I have been in refusal. As you must know well, being engaged in my profession, I have never been connected with any state secrets or security, dealing only with experimental oncovirology and immunology of experimental tumours — quite an open branch of science. In spite of this, my family and I were not allowed to emigrate to Israel and none of the officials, despite my numerous applications, took the trouble to give me any good ground for the refusal. By now, I repeat, for four years, I have been without a professional job and practically without hope. All my efforts to get any decent job have failed.

We appeal to scientists from all countries, including our Soviet colleagues, to use all their influence so that Dr Irlin, together with his family, is allowed to leave the Soviet Union to live and work in the country where he and his family wish to stay.

SIR — I wish to support in the strongest possible way the appeal of Dr André Lwoff, and other Western biochemists and geneticists on behalf of Dr David Goldfarb whose exit visa for Israel has recently been withdrawn by the KGB (see *Nature* **308**, 679, 766 and **309**, 104; 1984).

I have known and admired Dr Goldfarb since he came to work in my microbial genetics unit at Hammersmith Hospital, London, some twenty years ago, and respected him as among the most honest, able and innovative Soviet geneticists of the post-Lysenko era. To those of us who have known Dr Goldfarb well, he has always reflected credit on the Soviet Union for his work on microbial genetics. I therefore found his harassment by the KGB when he applied for an exit visa in 1979 not only unjust but incomprehensible, especially in view of the assertion by the Soviet Academy of Sciences that he knew no state secrets. He also demonstrated his courage and patriotism at the siege of Stalingrad where he lost a leg. The latest withdrawal of his visa, again approved by the Academy of Sciences, on the eve of his departure for Israel savours of paranoid persecution and causes great distress to his many friends abroad in view of his advancing years and poor health. I therefore hope, in the interests of all those who support goodwill and international collaboration in science, that Goldfarb's case will shortly be resolved in his favour.

WILLIAM HAYES
Department of Botany, Australian National University, Canberra, ACT 2601, Australia

Skew physics

SIR — I was struck by the remarks on Fritz London in your recent article (*Nature* 10 May, p.109). Amongst other qualities, London was gifted with modes of apprehension of physical problems that were skew, or at any rate out of line with those of his contemporaries, with the consequence that some of his publications at first lacked the full impact their importance warranted. As some compensation, his originality enabled him to grasp more confidently skew developments presented to him.

I was fortunate to have personal experience of this trait in relation to my earlier letter (*Nature* **132**, 1002; 1933) on the change from "aromatic" to "metallic" electrons in organic compounds. This text was written with some unease because of its novelty, but on my walking back from posting it to your offices I was introduced to Fritz London by F.A. Lindemann, who was chatting with him at the entrance to the Old Clarendon Laboratory at Oxford. Rather tremulously, I showed them my letter. Lindemann read this politely, and said little, but Fritz London immediately grasped what it was trying to focus on about the unusual physical properties of aromatic molecules, such as their large diamagnetism, and reassured me. He himself later developed this theme more fully.

His kind of responsiveness raises the interesting educational problem of whether teachers may be justified in describing select skew approaches to physics to their pupils, not only to leave loose ends for innovative developments, but generally. It can be argued that the best informed financial patronage for research, and most valuable support for research programmes, is to be sought from managers and directors who understand a mixed conceptual language much more readily than would physicists with much stricter training in scientific communication.

A.R. UBBELOHDE
Department of Chemical Engineering and Chemical Technology, Imperial College, London SW7 2BY, UK

Sea as dark as wine

SIR — When Homer sang of the "wine-dark" sea (see *Nature* **303**, 568, 1983; **307**, 590; **309**, 204, 1984) what he had in mind must surely have been its darkness, rather than the colour, and "dark as wine" might be a better translation. After all, one can say that "her eyes sparkled like diamonds", without implying that they were of the same colour.

Ionian Greeks knew all about wine, but with what other fluids would they have been familiar, to be compared in darkness with the sea? Blood would not have done, and the Homeric heroes had no use for ink, which was a muddy concoction available, if at all, only to scribes. So, gazing into the mysterious depths of a calm dark sea, how better could the poet then have described it, than with his simile of the transparent darkness of a full cup of wine?

Luddites defended

SIR — It has become fashionable to describe negative attitudes to technological change by making an analogy to the Luddites. Terms such as "neo-Luddite" or even "latter-day Luddite" are appearing regularly. The most recent I have noted is in David Sills' review (*Nature* 10 May, p.185). p.185).

The term seems to imply a senseless denigration of new ideas, an attempt to retain the old. I would suggest that this is a gross generalization. It strikes me that the original Luddite leaders were more concerned with the terrifying effects that new technology was to have on the workforce. Whilst their methods of protecting people from unemployment, with its associated evils, were violent and destructive, their intentions were highly honourable and deserving of our attention today.

RICHARD MORRISH

Now Calmodulin-Sepharose®4B and Calmodulin are available from Pharmacia

Biologically tested calmodulin, its purity checked by amino acid analysis, electrophoresis and UV spectroscopy, is available immobilized on Sepharose 4B and as an essentially salt free, freeze-dried preparation.

These reliable, high quality products are used to study:

- *Cyclic nucleotide metabolism*
- *Ca^{2+} transport*
- *Contractile processes*
- *Glycogen metabolism*
- *Control of the NAD/NADP ratio*
- *Cytoskeletal control*
- *Neurotransmission*
- *Phosphatases*

Calmodulin-Sepharose 4B is supplied as a swollen gel in an economical 10 ml pack. It has approximately 1 mg calmodulin/ml swollen gel. Each batch is carefully tested for its Ca^{2+} dependent ability to bind and release phosphodiesterase.

Freeze-dried calmodulin is available in large 2 mg packs. A trace amount of $CaCl_2$ is present to ensure protein stability. Each batch has to pass stringent tests for purity and has a biological activity of approximately 80 000 U/mg protein.

Send for the free data sheet for a comprehensive survey on the applications and uses of these versatile products.

Contrasts in near-similarity

The Low Countries, Belgium, Luxembourg and the Netherlands, are far from being the homogeneous corner of Northern Europe that geography suggests.

THE hallmark of densely populated Europe is diversity; the Low Countries — the Gallic name for the regions bordering the estuary of the Rhine — are Europe in microcosm. Socially and politically, the Netherlands, Belgium and Luxembourg between them embody all the features of a continent repeatedly reworked by twenty-three centuries of recorded history. Since the Roman pacification of northern Europe, the strategic importance of this patch of land has given it the unenviable distinction of being that on which the great European armed conflicts have been staged. The marks of those battles are still plain to see in every other rebuilt market square. The wonder is that so much remains of the distant past — cathedral spires glimpsed from miles away over flat alluvial farmland, the art treasures of many centuries and the indomitably cosmopolitan conviction that the whole of Europe can be run from the back yards of these northern fens.

The following pages will also show the Low Countries to be in microcosm representative of Europe's contemporary problems. Once comfortably prosperous economies are now, surprisingly, less so. Communal divisions rooted in language or religion are now openly contentious, with the result that tiny nation states are being further splintered into autonomous regions. Fierce public arguments rage (especially in the radical Netherlands) on questions such as the safety of nuclear power stations or the prudence of providing hospitality for other people's nuclear missiles. (Last week, the Dutch coalition government postponed for another eighteen months the decision whether to carry through its 1979 obligation to provide sites for nuclear missiles of the North Atlantic Treaty Organization.) And Belgium and the Netherlands must approach Europe's contemporary dilemma of how to join the new high-tech industrial revolution while keeping public expenditure to a minimum.

That Belgium and the Netherlands should be faced with such different problems is not surprising to Europeans, but may catch others unawares. In reality, the two countries have little more in common than their place on the map. (Luxembourg is something else again.) Historically, the Netherlands has the greater claim on public attention, perhaps because so many Dutchmen were quick to recognize the importance of what was happening in southern Europe during the Renaissance. Erasmus, part-philosopher and part pre-Newtonian physicist, was one of them. In the seventeenth century, van Leeuwenhoek did for the microscope what Galileo had done for the telescope, showing the potential of primitive pieces of glass. Huygens, whose physical insight made wave propagation through a medium a branch of mechanics, was a Dutchman. It remains something of a miracle that the University of Leiden should have served as a durable bridge between nineteenth-century physics and what came later through the work of H.A. Lorentz and his successors, notably Kramers. It is understandable that the government of the Netherlands should now be moving with great caution to impose external direction on the patterns of research in universities which have so recently been able to do so well.

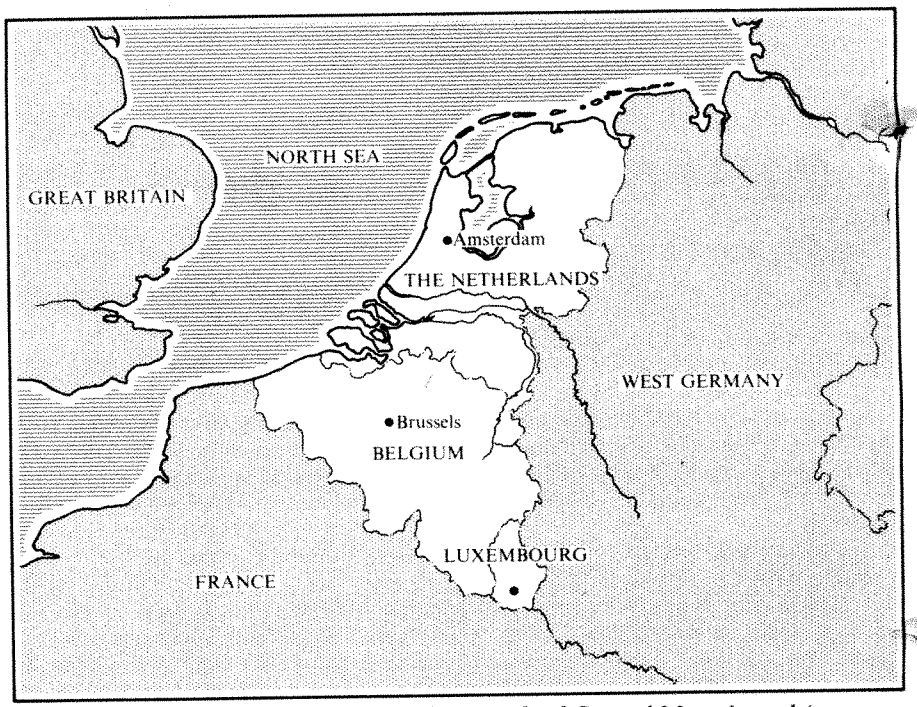
Industrially, the two countries are also sharply different from each other. Mainland Europe's late response to the industrial revolution of the nineteenth century prompted quite different responses in the two small northern states. Both have made their way in the world by being industrious, but in very different ways. The Dutch seem to have concluded that it would be uneconomic just to make electric light bulbs simply for themselves and so Philips has made light bulbs for half of Europe. Now there are Shell and Unilever as well, all of them enterprises based squarely on a mercantile flair and the self-conscious application of research and development to the manufacture of products that people elsewhere will buy. Is this a continuation into the present of the old Dutch willingness to travel abroad or a measure of the strength of the Dutch universities? Belgian industry has taken a different route. Until quite recently, Belgium has been to northern Europe what Birmingham used to be to England, a conglomeration of small-scale metal (and diamond) workshops. (But now there are international pharmaceutical companies, as well as other people's multinationals such as ITT.) Is it that Belgium has had only modest expectations of what its universities can accomplish for its industry, at least until comparatively recently?

Such questions prompt over-simple answers. Since the Second World War, and with the unwinding of overseas empires in both Belgium and the Netherlands, it has been plain that each of them can function competitively only as a part of a larger European enterprise. It is therefore no accident that the Benelux economic union should have been a precursor of the European Communities. Each of them now gives outsiders the impression that it is marking time, waiting for the international climate to change for the better. The Dutch, meanwhile, have been flexible and ingenious in hitching some of their academic science to international enterprises, especially in fields such as astronomy. Belgium, with its language problem, is by contrast being forced along a path — separate pots of public money for separate linguistic regions — that cannot but be cramping for Belgian universities and, ultimately, for Belgian science. Can the mutual suspicion of the Walloons and Flemish be that important to them both?

So, it seems, the years immediately ahead are bound to be crucial for all three of the Low Countries. Will progress towards European integration make it easier for them to concentrate intellectual resources, and research and development in particular, on a smaller range of objectives without at the same time running the risk of neglecting activities that turn out, in the course of time, to be even more important? This, the recent dilemma of most European states in science and technology, is necessarily more acute in Belgium and the Netherlands than elsewhere. The Netherlands, with its established international connections, is better placed than Belgium, now bent on modernizing its metal-working industries and everything else in sight. Both countries would, however, benefit enormously from the more thorough integration of European academic institutions, universities and basic research establishments. Indeed, the problems encountered by Belgium and the Netherlands are a pointer not merely to a potentially fruitful area consistently neglected by European politicians (which will become more important as other states accede to the European Communities) but also to the way in which the rest of Europe does not fully share the benefit of the intellectual resource of these northern states. □

Science in the Low Countries

THIS survey of science in Belgium, Luxembourg and the Netherlands has been compiled and written by Robert Walgate, Chief European Correspondent of *Nature*.



Geography

Small lands, big industry

ARE the Low Countries small? Some 14.3 million people live in the Netherlands; 9.9 million in Belgium; and 365,000 in Luxembourg: a total of a little more than 24 million people, less than half the population of Great Britain, France, Germany or Italy, and a tenth that of the United States. But their joint population density is three times that of France next door. And these people in their cabbage patches are highly productive: the Netherlands has probably the highest ratio of gross national product per square kilometre (£2.4 million) in the world.

Moreover, in the small continent of Europe, the Netherlands can claim to be medium-scale: politically, it chooses either to trail the big countries or lead the small, according to the policy it is pursuing. Smaller Belgium is further divided, roughly in half, by the constant regional sniping between Dutch-speaking Flanders in the north and French-speaking Wallonia in the south. Luxembourg, of course, is tiny, a little anomaly in modern Europe.

Geographically most of the Netherlands and the northern half of Belgium form the delta of the great river system of the Rhine, the Meuse and the Escaut rivers; and nearly half of the Netherlands (and more than half its population) is below sea-level (the windmills were — and are — water pumps, not flour mills). This gives both countries good flat agricultural land, and the Dutch, in particular, are renowned for their farming and agricultural science.

One Dutch university, Wageningen, is devoted to agriculture. Apart from that, the Netherlands has nine full universities, and three technical (engineering) universities. Three of the universities have religious affiliations: the Free University of Amsterdam (Dutch Reformed) and the Catholic Universities of Nijmegen and Tilburg.

Apart from agriculture and a strong dose of Calvinism (now forgotten, to judge by the drugs and flesh-pots of Amsterdam), in the past the Dutch have relied on sea-trade (which gives them an affinity with the English), and good business sense; but they also manufacture. In fact Holland supplies much of General Motor's steel (sea transport to Detroit up the St Lawrence is "almost free", they say). The Dutch also boast the headquarters of the multinationals Philips, Shell and Unilever, and are strong in the fermentation and pharmaceuticals business. Since the 1960s they have enjoyed a bountiful supply of natural gas from Gröningen in the north of the country, which some say has distorted the economy and the spirit of the Dutch.

Belgium has coal in Wallonia, and hence steel and the chemical industry — dominated by Solvay (which supported the historic Solvay conferences in physics). Flanders developed on textiles — for centuries it made cloth from British wool, and Belgian lace is famous — but it also has the almost independent offshoot of Bell Telephones, Bell Antwerp, flourishing foreign investment and is turning rapidly to new industries. It is thus outpacing the heavy industry of Wallonia, a circumstance which has now become a major cause of regional friction.

Belgium has six universities (three Flemish and three French) and eleven regional "university institutes". Two of the universities are Catholic (Leuven and Louvain-la-Neuve) and two free, that is neither fully state-controlled nor religious (the Flemish and French free universities of Brussels).

Luxembourg, finally, in the far south and hillier part of the region, has been predominantly a steel and metals town (half of its industrial employment was in steel 10 years ago, although the fraction is now declining and steel production with it). After steel, Luxembourg has rubber (Goodyear's European laboratory is there) and banking (it is like a little Switzerland to rich Belgians) and is now developing new industries. It has the first year of a university, and something approaching an academic hospital. □

Charlemagne's fondness for bathing

THE Netherlands, Belgium and Luxembourg are the northern tip of a corridor of states that once separated the Germanic from the French empires; and as rebellious buffer states, they have often been warred over — or upon. (It is appropriate, said one sardonic Belgian, that the North Atlantic Treaty Organization NATO has made its headquarters in Brussels.)

It is believable, although not necessarily true, that the blood soaked countries owe their existence to Charlemagne's love of a hot bath. This last great unifier of Europe was crowned in AD 800 and made his court at Aachen, now a German city but just over the border from the southern Netherlands. He chose that city, it is said, because as a lover of the good life he liked to bathe in its hot springs — there may have been some sound military reasons too, as Charlemagne was a soldier as well as a lover of baths, but these reasons are unclear. But for whatever cause, Aachen was the focus of his empire when he was planning its division among his sons, and Charlemagne seems to have planned the division symmetrically.

But even Charlemagne's plans could come adrift, and in the event, only one of his sons survived, leaving the empire intact for a generation. That son then enacted the division among his own three sons: one took the Germanic lands, so providing the early foundation of Germany; one took what is now France; and one was granted a corridor of land which ran from the low countries south through Alsace-Lorraine (now part of France) and on to the Mediterranean. These were the buffer states between France and Germany, of which the low countries were for long the marshy and neglected north.

The present states were first defined when Belgium seceded in 1830 from the United Netherlands (a product of the Napoleonic wars) after a revolution in Brussels; and second when Luxembourg won its independence from the Netherlands in 1890. In royal terms, they now form two kingdoms and a duchy (Luxembourg). □

Economics

The end of equality

ONE of Belgium's grander scientists, Nobel Prize winner Ilya Prigogine, is concerned — among other things — with a topic that proves strangely appropriate for this review of science politics in the Netherlands, Belgium and Luxembourg: the matter of "strange attractors".

These are states in phase space towards which complicated systems may converge, somewhat like a ground state in classical physics.

So Belgian and Dutch science, it seems — to leave Luxembourg aside for the moment — have converged along quite different paths towards the same strange attractor. Moreover it is one that seems to afflict much of European science: a kind of balkanization of science politics that ends up distributing government resources more or less evenly, or at least much more evenly than is good for the health of research — which, with some exceptions and caveats, often depends on the very inequitable principle of the best getting the most.

But "equitable distribution" has developed to an extraordinary degree in the Netherlands, where until very recently only 7 per cent of basic research funds in the universities went through a semblance of national peer review and where, of that 7 per cent, perhaps only a quarter went through a really serious competition for funds. Despite government attempts to introduce selection, and hence a kind of scientific aristocracy, as recently as last November a tongue-in-cheek science policy official said "we don't like to make kings and queens here". This was not treason against the Dutch Royal family: he was drawing attention to another honoured Dutch tradition, even distribution — a belief in a good solid mean value rather than peaks and troughs.

This Dutch situation seems to stem, perhaps as does much of the Dutch character, from centuries of cooperation to drain the land and keep out the sea; and it was emphasized by the democratic revolution in the universities in 1968. But it can also be seen as a Dutch version of a general European principle: that academics receive funds in proportion to their academic-political weight. (Perhaps that in turn stems from the long pre-scientific history of academic bickering in Europe.) It is evident throughout Europe that there are academic kings, and that — more than is the case in, say, the United States — kingship does not necessarily correspond to ability or productivity. In the Netherlands, this principle has merely been reversed. In the Netherlands, university democracy — and the very fear of kingship — has merely spread the king's rights over the whole academic community. This then taxes the government

Table 1 Gross national product (GNP) and population

	Working population (million)	Area (10^3 km^2)	GNP ($ thousand million)	GNP per head ($)	GNP per km^2 ($ million)
Netherlands	5.0	41	106	23,000	2.6
Belgium	4.1	31	79	21,000	2.5
Luxembourg	0.16	2.6	4	25,000	1.5
United Kingdom	26	244	400	15,000	1.6

These figures demonstrate the relative economic weakness within the low countries of Belgium, in terms of per capita GNP, but the strength of the whole region relative to the United Kingdom.

Table 2 National research and development budgets

	Government			Industry	
	Total ($ million)	% GNP	Defence component	Total ($ million)	% GNP
Netherlands	1,007	0.95	3%	986	0.93
Belgium	333	0.42	0.3%	698	0.93
United Kingdom	3,821	0.95	50%	3,423	0.86

This table again shows a relatively poor performance by Belgium — in terms of government support as a fraction of GNP, which as Table 1 shows was itself low relative to the Netherlands. Allowing for the small fraction of the low countries' spending on defence science, the Dutch research and development budget fraction works out somewhat higher than expected in an advanced country, and the Belgian slightly lower. There are no official science budget figures for Luxembourg, but an unofficial estimate puts government research and development at a miniscule 0.1 per cent of the Luxembourg GNP: most of the research there is applied research done by the steel and rubber industries.

Table 3 Division of government research and development budget

	Applied research in industry	Applied research in agriculture	Fundamental research	Human and social sciences
Netherlands	14%	8%	56%	22%
Belgium	35%	6%	41%	18%
United Kingdom	33%	8%	47%	12%

This indicates the low weight given to industrial research support by the Dutch government, and the relatively high weight given to the social and human sciences in both Belgium and the Netherlands. In the Netherlands at least, these sciences have been adopted enthusiastically by government, the administration, and politicians as an aid to policy-making. And the Dutch neglect of industry in fact reflects the great weight of the so-called "big five" companies in the Netherlands — including Philips, Shell and Unilever — which between them cover 70 per cent of Dutch industrial research and development. The big five have been thought, no doubt correctly, well-able to look after themselves. The neglect, therefore, has been of Dutch small and medium size industry; but the government has made and is making moves to correct the imbalance.

Table 4 University research funds

	University students	University research funds ($ million)	Proportion through research councils	University research as % of all national research and development	University research funds per student taught ($)
Netherlands	147,000	522	7%	25%	3,550
Belgium	110,000	223	27%	21%	2,030
United Kingdom	251,990	906	46.2%	11%	3,595

Here we calculate the research funds available (including the research proportion of academic salaries) per student taught — a figure which gives a measure of the research intensity of the universities compared with teaching. On this table the Dutch universities have nearly double the research intensity of the Belgian. This makes the Belgian universities look poor, but academics in Holland admit that their universities have been among the richest in the world. Other figures of interest: the small fraction of Dutch research funds that goes through research council peer-review, and in both countries the high proportion of university research as a fraction of all research and development (about double the fraction in the United Kingdom). These figures are based on the latest OECD science and technology indicators (1984) which refer to the year 1979. The figure of 46.2% for the proportion of UK university research sponsored by resource councils relates to 1980/81.

proportionally, in a kind of royal brotherhood.

The problem is only slightly easier in Belgium, where funds have been distributed more unevenly, and to some extent on scientific grounds — particularly since the institution of a prime-ministerial "top-groups' " fund in 1970. However, a large fraction of funds has been distributed among the nominally six complete universities according to what Belgians describe as "the theory of the four forces" — equal distribution between Catholic and non-Catholic, and between Flemish (the Dutch-speaking northerners) and Walloon (French-speaking southerners).

As a result, then, professors and researchers in both countries, in bulk and on the average, have received their money more through mere queuing, more through the essentially political demand of "fair proportion" than through scientific judgement.

However, Belgium and the Netherlands are not entirely without systems of selective funding, and the occasional watering of the best plants can and does have dramatic effects: as, for just two examples, with Prigogine's own laboratory, and astronomy in the Netherlands.

Moreover — and hence the headline above — things are changing in the Low Countries. The well-worn "economic crisis" is forcing drastic reappraisal of the equal-shares approach and, with very different mechanisms and effects, selectivity is increasing. The Netherlands is making the closest approach to extending peer-judgement in the basic sciences; Belgium is failing in this, and at the same time reducing its support of basic science. Both countries are increasing judgement at the level of national and — in the case of Belgium — regional politics. In this way, applied scientific and political criteria are encroaching very fast on the Belgian universities, faster than is probably advisable. These different approaches and their consequent problems are outlined in the following pages. □

The Netherlands

Shadow boxing with peer review

THE most fundamental change facing researchers in Dutch universities is not a loss of funds — though they face that too — but an increase in national refereeing of what funds there are. This threatens (or promises, according to your point of view) to change the whole basis of support for the bulk of basic research in Holland — and to put a new policy instrument in the hands of the government.

Until recently, over 90 per cent of the research funds received by the universities underwent no national review. The money was — and much of it still is — distributed at university level, by local research councils. These, with some exceptions, such as the Leiden council which has developed a method of selection based on citation analysis, find it difficult to make negative judgements about colleagues' work. And even at Leiden, such judgements are painful: because citation analysis can be challenged; because council members are judging the work of friends met daily; and because — given the small scale of a single university — often the work to be judged is in a discipline far from entirely understood by most council members. As a result, of course, money has been largely distributed through a system of courtesy rather than quality.

This may be gentlemanly; it may allow some rare lines of research to be followed that would otherwise be forgotten; but it leads to a loss of competitive edge, and it certainly does not suit times when money is short.

Hence the introduction of a system called "conditional financing", which offers a gold star — "protection" — to research projects that gain approval by national committees.

But for the moment, although many gold stars have already been awarded, no one really knows what this approval — or the lack of it — will mean. For the time being, the money comes to all much as before: the scheme has been one merely of labelling, the marking of a cross on the door. It is the time, in Dutch research, of the phoney war.

However, protection, says the minister of education and science Wim Deetman, does mean that a project will be exempt from further unforeseen cuts in university spending for five years. (Or at least, he says he will give that protection "all his political weight".) Moreover, the real selective war among projects is to come: it will begin in a year or two. "Research has finally become visible as a separate element in the budget", said a spokesman of the ministry of education, ominously, and in future "it could be re-allocated between the universities".

To some minds, this re-allocation, favouring some universities for research, is the whole purpose of conditional financing. But this runs hard against the Dutch tradition of equal treatment. A common plea is that the Dutch universities are really much the same: that there is no Harvard or Oxford. The fact is that there are variations, but no common pattern. Take medicine, for example: one university has an 85 per cent success rate in the final examinations; another has under 60 per cent. But, says Professor Veltman of the Technical University of Delft "It's very difficult to find extreme differences, because from year to year we've always made sure we've had the same amount of money, the same procedure for attracting professors, and more or less the same experimental facilities."

However, Veltman admits occasional differences in quality "because in some places you have a very good man, or a very strong team", and it is exactly this kind of difference that conditional financing will emphasize.

There is an unofficial target: that in any university, approximately half its research should be covered by conditional financing (that is, have won approval in the national committees), the rest coming unrefereed as before. But so far only about 30 per cent of university research has been subject to the scheme, so not enough research has yet

ZWO gives benefit of the doubt

THE Dutch national research council for basic research, ZWO, judged two out of three projects submitted by universities for the protection of "conditional financing" (see below), and rejected one in five. But they claim they were only "marginally involved" in the exercise.

ZWO is familiar with the distribution of grants awarded by peer review. But the council had to adopt a completely different selection procedure, and new committees, to assess the conditional financing projects, says its director Professor R. van Lieshout. ZWO had no role in defining the nature of a proposal; nor how it should be judged; nor even in what fields the council should judge. "In that sense we were only marginally involved". The minister's instructions were "too loose, too open" so the ZWO judgements were made "on someone else's terms of reference. . . Which were not clear and sometimes contradictory. . . "

The minister imposed three conditions, of which the most extraordinary was that the review should *not* look into a project in depth. Rather, as ZWO saw it, the reviewers were only to investigate a group's record, its potential, and whether its project was serious or window dressing.

But very often all the ZWO committees (specially convened for the purpose) could do was assess records, for the projects themselves were defined so sketchily that assessors could not decide whether they were good or bad. "We could not consider, as usual for a ZWO proposal, who was going to do what when, whether the project was well-planned, whether the researchers had the right contacts abroad, whether they even had the equipment — the review was much lighter. It was more a matter of trust, understanding, and giving the benefit of the doubt".

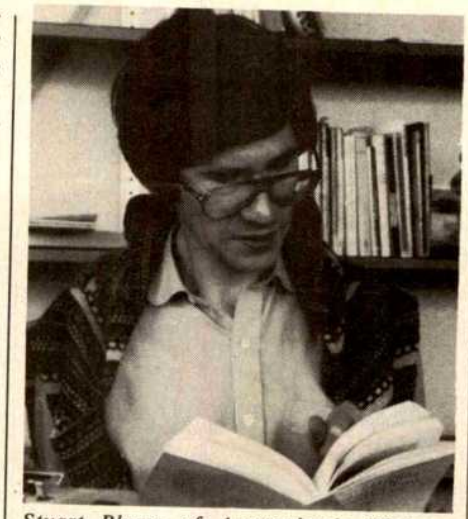
Nevertheless says van Lieshout "Very often the people on the special committees knew the groups, what they had done and could do. So they could detect tricks, and fill in what was not on paper. So that's why here at ZWO" — despite everything — "the conditional financing reviews worked quite well. . . ". □

passed through the scheme to start re-allocation. When this happens, in two or three years' time, universities that have gained few approvals will see their unrefereed research funds diminish in proportion, and to those that have more approvals, more funds will be given.

That is when the conditional financing fireworks may begin, not least because of a flaw in the whole system. The refereeing system for conditional financing was established in haste, and it is a rickety, untested Gothic structure, full of anomalies. The best and most obvious projects are getting through safely, but the middling and the unusual face a lottery. But the ministry will keep the system, based on *ad hoc* committees in a complex of different non-governmental institutions, and a set of ambiguous instructions.

According to the ministry, some things may be changed, but not the main structure. However, a spokesman admitted "We have to create more unity from subject to subject. Some judgements were prospective, some retrospective. . .". The ministry has been thinking of improving its guidelines. "There has been a problem of clarity in the decision-making." But "we do not think in practise there were real problems. . . There will be fine tuning."

However the whole exercise was so novel for the Netherlands, it is no surprise that the fine tuning will, in some subjects, be more like a complete change of channel.



In chemical engineering, for example, projects were at least initially assessed by pure chemists with, as one engineer claimed, irrelevant ideas of what chemical engineering research should be. And in biochemistry, a relatively new group in carbohydrates at the University of Amsterdam

". . . there has been a problem of clarity in the decision making . . .

was judged, says a group member, on its publication record by a panel that knew nothing of the work or the group.

The group failed to win approval. But, says the aggrieved group, the panel should have used prospective criteria as the research was building up, and suffered from a "blinkered attitude" to the importance of carbohydrates in cell biology. Moreover, the group has set about proving its case by collecting hundreds of letters of support, and independent referees' reports on its work, from around the world.

And beyond such hearsay, the ministry of education, aware of criticisms, commissioned an external report on the assessment procedure. It was prepared by Jack Spaapen of the "Science Dynamics" group of the University of Amsterdam, headed by the English professor Stuart Blume, and details an extraordinarily varied and haphazard process of assessment. Spaapen studied the work of two assessment commissions from the basic research council, ZWO, three international *ad hoc* commissions, and commissions from the Royal

Stuart Blume of Amsterdam's "Science Dynamics" group.

Institute of Engineers (KIvI), the Royal Academy of Sciences (KNAW) and the National Agricultural Research Organization (NRLO).

All adopted "very different" procedures, which went beyond differences appropriate to tackling different subjects, Spaapen concluded. Some used committees to arrive at consensus; some "committees" never met, but interacted only on paper, with decisions taken by the chairman alone; some fed back criticisms to applicants and suggested re-application; some even invited applicants to the review. Writes Spaapen ". . . these problems largely derived from a divergence between the [conditional financing] procedure and usual evaluation roles. Uncertainty as to the precise function of their evaluation (and as to the consequences of a "no" in a given case) appears to have been common."

Perhaps as a result, rather few proposals were ultimately rejected (about 25 per cent), although the ministry claims that this was more than expected.

Another problem is the fear of increasing governmental control of the otherwise highly independent Dutch universities. The conservative government has not hidden the fact that come re-allocation, it may indicate some priorities in this great swathe of university research over which it previously had almost no knowledge and certainly no control. And since the financing involved is direct, and the assessment procedure so haphazard, since there is no organized buffer, no coherent policy-making research council, between government and spenders, the possibilities for control are great.

To government, the opportunity must be very tempting: but Professor R. van Lieshout, director of ZWO (which controls the 7 per cent of funds normally peer-reviewed) reacts very strongly to this idea: "It is of course a very dangerous development . . . My colleagues in Germany were quite shocked when they heard this. They said 'that's the way it started in the thirties'. They're very sensitive about such things there." In fact, says van Lieshout, there is no serious intention of such political control in the Netherlands, but "sometimes things slip in a certain direction even if no one intends them to; you have to be very careful." □

Universities

Cuts concentrate the mind

UNTIL the mid-1970s, Dutch university researchers were sitting very pretty. The rector of the technical university of Delft, asked if the Dutch universities had been the richest in the world, replied, laughing: "Oh yes!" Buildings, equipment and staff were all available as needed. In Delft, there were two technicians for every researcher, "a figure you will not easily find elsewhere in the world."

Then the oil crisis led to the first budget cuts. At first the cuts were mild. The government (then socialist-dominated) opted for "restrained budget growth" of 1 per cent per year in real terms. In the universities, this became a little harder: a real-terms freeze. But this was just play-acting compared with what was to come.

The new (conservative) government of 1977–78 faced inflation. It sought real cuts — and the university budget shrank by 1 per cent. But these cuts were only in buildings, materials, research equipment, and computers; there were no sackings, and — according to a government spokesman, the cuts posed "no problem". But gradually the knife came closer to the bone. The ministry decided not to compensate for inflation in 1979. Nor in 1980. Nor in 1981. Then the first real pain: over and above the "inflation penalty", in 1981 the universities faced a real budget cut — in personnel — of DFl 60 million (around 2 per cent, just over £1 million per university).

Then in 1982, the government demanded further, more sizeable cuts: another 10 per cent. Now the universities were in trouble. The ministry felt that savings could not be found on buildings or materials. The only place for further cuts was staff.

The ministry adopted three main principles:

- First, the cuts had to protect research. So cuts had to be found in education: in reducing the teaching hours per student. (Which, says the ministry, was a high figure in the Netherlands.)
- Second, the cuts were not to be even: said an official involved "we had to identify areas with the least and worst output: we had to make qualitative choices".
- And third, the present (right/centre) government decided not to make these choices itself.

So the problem was thrown to the universities, who had always pretended each

was equal to the other but now had to make distinctions among themselves — or face the minister making them himself. The bluff was called.

Yet it took the universities only 6 months, until March last year, to negotiate the 10 per cent cuts, and indicate where concentration (the elimination of departments at some universities, or their merging at another) could take place. This was fast work. So had there been substantial agreement?

"Yes", claimed one rector "but it led to a lot of trouble within the universities, as the democratic councils did not agree with what the boards had done . . .".

"No", said the ministry, the universities had fudged a lot of issues. Minister Deetman set himself the task of making sense of the universities' proposals, and of reaching decisions which were, his staff claim, "very careful, but on the other hand very clear". After long consultation, in November last year the minister offered each university a contract, covering the cuts they would suffer and a politician's guarantee of defence at that line.

This was it, said the minister: there would be no further changes. Two university councils (the university parliaments) told their boards not to sign: Amsterdam and Delft. But Deetman has threatened that he will simply not pay for departments to be closed under his plan. His list includes 34 departments, from the very small to the very large, which should be closed. Some departments, for instance geology at Leiden, are already closed.

Overall, the cuts aim to save the ministry of education some DFl 280 million (£70 million) from 1987. But on Deetman's orders, the cuts went a little deeper, reaching about DFl 310 million to provide a surplus of DFl 30 million for redistribution on new research projects. Some of the savings will go to biotechnology in Amsterdam; some will be used for a new pharmacological research laboratory in Leiden; some will go on psychology; and some on informatics, mostly in support of a ZWO (national research council) foundation in Amsterdam.

On the whole the government has protected the provincial universities; so the universities of Groningen in the north, and Twente in the east, were "saved"; they also had to economize, but less than the big, central universities in the "ring city" of Rotterdam, Delft, the Hague, Amsterdam and Utrecht where most Dutchmen and women live. As one president put it to this Englishman, "the general policy was that London can look after itself!"

The University of Limburg, for example, will actually get some new departments. "This is a political decision — I think that the academic Netherlands could easily do without that university" complains one "ring city" rector. Limburg is in Maastricht (in the southern tail of the Netherlands), rather distant from other universities, in an old coalmining region,

Although not faced with Belgium's regional troubles (see page 507), the "ring city" of Rotterdam, the Hague, Amsterdam and Delft is looked on with envy by "provincial" towns.

20 km from Aachen in West Germany. "You get the ridiculous situation that the most expensive academic hospital in the world is in Aachen, and the most expensive in the Netherlnds is in Maastricht, and you can see the one from the other — it's ridiculous. It's all to do with a decision to redevelop the area" says the complainant.

As for the three "private" religious universities, very little of the religious element is left in them but they have sometimes been able to make use of it during "concentration". It gives them a certain power, through religious connections, in parliament. For example the Roman Catholic university of Nijmegen was to lose Roman studies, but said this was impossible because it was RC. But the Protestant Free University of Amsterdam had the choice of saving sociology or dentistry, and they chose the latter, and were defended on the choice, whereas on religious grounds the former was more arguable. It thus appears that these universities simply use religion quite cynically, when it is useful to them.

In many ways, then, Deetman has achieved his aim — an uneven distribution of pain, although the unevenness has not always been defensible on academic grounds alone.

But the story of university concentration is not over yet. The next problems to face the minister will come in the courts, where the government must defend seven particular decisions. The most serious — or at least spectacular — concerns the justice of the closure of dentistry in Utrecht, the biggest dentistry department in the country and the biggest of all departments to be closed, saving DFl 20 million (£5 million). The closure has created much emotion, but the ministry won a first hearing of Utrecht's case in a lower court (in private chambers).

And there are still some other loose ends: in some subjects only the budget cuts have been defined: in sociology, economics, law, and medicine, including the academic hospitals, one of which — in Amsterdam — has been threatened. Deetman will decide in these areas this year if a department or two has to go. □

Degrees on the dole — early retirements

THERE are some 160,000 Dutch men and women with a degree. Of those, 15,000 are unemployed. University lecturers and professors are now adding to the figures, as budget cuts bite deeper.

The Technical University of Delft, for example, has about 4,000 staff, of which 1,400 are scientists. Some 600 people must go — and although the university can choose who should leave, strong university democracy will put greater pressure on the academic than the non-academic staff, the rector believes.

Professors themselves are not exempt, and as a further, nationwide measure, a whole cohort of professors must retire this year. The retirement age for a Dutch professor falls this summer from 70 to 65, to begin a 20 per cent reduction in full professorships in the Netherlands from 2,800 to 2,260 over five years. A total of 150 over-65-year-olds will be leaving in August, most of them not to be replaced.

But when it comes to redundancies, Dutch university staff benefit from being civil servants. The rector of Delft claims he often wonders whether he should take redundancy, because there are so many advantages. A redundant civil servant may draw 80 per cent of his or her final salary for a long period, and may supplement this up to 100 per cent through a full-time job while part-time earnings (such as consultancies) are ignored.

So the scheme is attractive — at least for well-established academics with good links with industry. But there is a drawback — government has been warned that it might not be able to pay, and that will have to lower the rates, or limit the number of years they pay. So, says the Delft rector, "that makes many people shy of retiring at the moment. . ."

And says van Lieshout, director of ZWO "I don't think it's a very nice prospect at 32 to be told now you can go home with 80 per cent of your salary, and you don't have to do anything anymore. That's not something to look forward to."

But the early redundancies are "a human disaster" according to the president of Leiden. People leaving are often too specialized to find work. "But if I look at the opportunity to cut dead wood . . . I think that in the long term we will have better universities." □

SYSTEM 1:

Chemistry, performance, flexibility and support. The true value in DNA Synthesizers.

A Better, More Reactive Chemistry

SYSTEM 1 gives you fast, high-yield results, and the preferred phosphoramidite chemistry. SYSTEM 1 also includes convenient reagent kits with all the high purity reagents and solvents needed, each specially packaged under inert conditions to maintain quality.

Simple, Flexible Operation

Just insert your program, reset, dial-in the sequence and press AUTO and START for fully automatic operation. It's that easy. You can write and store your own programs, take full advantage of newly developed chemistries, and tailor SYSTEM 1 to your specific needs.

Automatic Synthesis Monitoring

SYSTEM 1 helps you perform DNA synthesis more confidently

with its integral Coupling Efficiency Monitor. It records the release of the dimethoxytrityl (DMT) blocking group, a measure of coupling efficiency. And, if the DMT level should drop below what you preset, SYSTEM 1 will stop automatically, so you don't waste time or chemicals.

And More Real Advantages

SYSTEM 1 gives you greater safety with separate modules for chemistry and electronic functions. It's also available as SYSTEM 1+, the DNA Synthesizer *plus* a matched HPLC purification system. And, most important, it's a total system backed by expert service and applications support, worldwide.

For more information on the true value of SYSTEM 1, contact your local Beckman Representative, or write: Beckman Instruments, Inc., 1050 Page Mill Road, Palo Alto, California 94304; or Beckman Instruments International, S.A., P.O. Box 76, 1211 Geneva 6, Switzerland.

BECKMAN

The leading German publishing corporation, Gruner + Jahr, has recently improved efficiency by installing a Philips MEGADOC information storage system for its journalists.

This system – based on Digital Optical Recording techniques – allows 4,000,000 pages of information collected from over 200 international publications (such as The New York Times) to be stored on our optical discs. Any fact or event can be summoned up on a visual display in a matter of seconds.

Esco Travel, one of Switzerland's largest travel agencies, with more than 300 branches throughout the country, have improved their service to tourists by installing an inter-active

Our optical discs give
for the busy journalist a

nstant access to facts-
l the discerning tourist.

computer system, making use of Viewdata techniques and LaserVision technology.

Not only can all details of travel, flights, departure times and so on be given directly on the monitor, but also full film information about hotels and resorts. So that the tourist can see exactly what he is booking before he decides.

These are but two examples of how Philips serves the business community throughout the world. For more information about Philips expertise world-wide, write to the Philips organization in your country, or to Philips, VOA-0217/N7, Eindhoven, the Netherlands.

Philips. The sure sign of expertise world-wide.

Going shopping for science

If 1968 brought socialism and democracy to the Dutch universities, the 1980s are certainly bringing reaction. But, remarkably, one "socialist" innovation is surviving: the science shop. Science shops offer a modicum of university facilities (time, expertise, research) to anyone who cares to ask for it.

Typical shoppers used to be trade unions or environmental groups, but the range was never limited. The most common clients (in Amsterdam at least) now appear to be women's groups; the trade unions, while retaining interest in *ad hoc* questions, are pushing the shops towards more programmed, project-oriented work. (There is a project, for example, centred on electronic banking and its effects on employment.)

But science shops were once the leading edge of university radicalism: now they are commonplace. Every university has one, although the first (Amsterdam's) remains the biggest, and they are recognized and supported by the university boards and the ministry.

So how did they take root? More to the point, how was it that the shops' founders — the familiar 1960s rag-bag of left-wing science students and lecturers — did not dissolve into factionalism, as such groups did in almost every other country?

Loet Leyersdorff, one of the prime movers of the Amsterdam science shop, now on the staff of the Science Dynamics unit at the University of Amsterdam, believes there were several reasons, but most interesting among them were two: First, the trade unions gave very early support to the movement, and were keen on practical results. And second, majority rule in the shops' management. There is a strong tendency to compromise in the Netherlands, Leyersdorff explains, and this Dutch tradition is very strong in Amsterdam. "Even old-fashioned Marxists are ready to compromise." □

Research council

Tiny budget — broad spectrum

THE Dutch have one research council, or coordinating body, to cover the whole of basic research — from the humanities to physics. Called ZWO, it is the only national body that allocates grants through thorough peer review (conditional financing aside). This gives ZWO a special prestige in Holland.

But ZWO has only a relatively tiny budget — covering, overall, about an eighth of Dutch university-level fundamental research. According to a recent survey the 13 Dutch universities spend around DFl 1,650 million (£410 million) on research. The ZWO is DFl 200 million (£50 million), about half of which is spent in its own independent institutes.

But there is overlap: ZWO institute directors often teach in universities. So there is a passing similarity between ZWO and the French national research council, CNRS. "There's exactly a factor 10 between us", laughs ZWO director Professor R. van Lieshout, a physicist from Amsterdam. "They have 23,000 people, we have 2,300, and there's almost the same factor in budgets. But they have many more institutes than us: for them, CNRS is practically only institutes; here it's 50/50."

But there is a cachet for a Dutchman in being funded by ZWO, as there is for a Frenchman funded by CNRS. ". . . we like to think so", says van Lieshout. "But it's not true in all fields", he says candidly. "For instance in social science some people think we're not helping enough and are funding the wrong things . . .".

For historical reasons, ZWO is most prominent in physics. There are five ZWO physics institutes, which consume half the ZWO physics budget; the other half goes to university groups. Of university physics spending, some 30 per cent comes through the ZWO. In some fields — such as plasma physics — there is work only at ZWO institutes.

In biology, the Royal Academy of Sciences (KNAW) plays an important role, mostly in the ecological sciences, but, says van Lieshout, the KNAW institutes are only loosely linked to university life, unlike ZWO institutes.

There are no biological institutes in ZWO, however. The biologists did not want them, it seems. ZWO supports about 20 per cent of all university basic biology, apart from its support for molecular biology through the chemistry division. (There are other substantial sources for biology through the agricultural university of Wageningen, through the medical research foundations.)

ZWO was founded in 1950, and began by integrating physics and mathematics institutes established four years earlier. The main aim was to tidy up the funding of basic sciences. After 1950, ZWO began to create other institutes on the model of the physics institute (FOM) and the mathematics centre. First to have institutes were chemistry and astronomy; and ultimately ZWO was spawning foundations in subjects such as theology, literature, linguistics and history.

Recently the budget has been "stable" — which in practise, because of falling university budgets, has given it an increasing, although still small, part in university spending. Last year the council won a small real increase (1.5 per cent) "through a technicality".

But next year the budget could go down. The finance minister of the conservative coalition government plans a further large cut in government spending. It is "almost unavoidable" that the cut will hit ZWO, van Lieshout fears "because they've cut the universities already, and protected their research through 'conditional financing'; so it's very difficult for them to go back and squeeze more out. They will be forced to cut organizations that haven't been hit yet. We're one of them." If there are cuts, the first item to be affected will be the support of research students, he says.

. . . in social science some people think we're funding the wrong things . . .

Neverthless, ZWO has optimistically requested an increase from DFl 200 million to DFl 204 million next year, partly to cover an increase in social science and humanities spending requested by the government; "Whether we can still have an increase for physics, medicine, biology and so on I don't know. We're trying to get one." ZWO has also requested a DFl 20 million capital equipment budget (on top of the DFl 200 million).

There should also be some money for ZWO in a recent, major government informatics plan: DFl 1,300 million (£325 million) mainly on education in informatics from the kindergarten to industry — "The whole population is to suffer from it!"

Has 1.5 per cent been enough to keep ZWO at the top? Probably not, says one ZWO staff member. A few years ago ZWO physicists tried to quantify what increase was needed just to keep up with new experimental techniques: they came to 4–5 per cent a year. But, says van Lieshout "Maybe our equipment budget was a little luxurious in the past here and there but it should not have gone down as far as it has."

ZWO needs to find cash to do something for LEP, for JET, to keep up its effort in astronomy, for apparatus for chemistry, and for a small computer or a computer link for the humanities and social sciences. ZWO is also seeking big equipment for research on surfaces: and would like to do joint research with the multinational

Astronomers spread far and wide

"DUTCHMEN live in a small country and we have to collaborate to get anywhere", says the chairman of the department of astronomy at the University of Leiden, Professor Harry van der Laan. Which may be one of the reasons why Dutch astronomy is so well known, particularly in the United States — where Dutchmen (mostly from Leiden) have headed many key facilities like the Mount Palomar telescope (for a long while the largest in the world), the astronomy departments of Yale, Harvard, and the US Naval Observatory (twice), and a Dutchman (Oort, previously director of Leiden Observatory) was ESO's founding father.

But Holland spends less on astronomy than France, West Germany or Great Britain, whether measured in proportion to either the gross national product or the population. And the country has fewer astronomers per head than the United Kingdom (the Dutch figure is comparable to the French and the German). The reason for the Dutch success, van der Laan suggests, is that Holland has had some great astronomers who have also created great Dutch schools (he mentions Kapteyn, Minnaert, and Oort).

Their students found Holland too small, says van der Laan. So Dutch astronomers colonized the world's telescopes and gained a reputation.

Moreover, in international collaborations Dutch astronomers have insisted that they win their share on the basis of research quality rather than any measure of funding, which given the size of the Netherlands would of course be small. In the collaboration with the United Kingdom over La Palma (in the Canary Islands) and Mauna Kea (Hawaii), under which the Netherlands pays a fifth the cost of various telescopes, optical and millimetre-wave, Holland pleaded strongly that it should not get a block allocation of 20 per cent. "I said we should compete on merit in the single allocation commitee — in which of course we will be represented by our scientists" said van der Laan.

Harry van der Laan — backing collaboration with Britain.

According to van der Laan the collaboration with Britain has been developing "beautifully", and has led to a "convergence" of the work of other universities in Holland. The Dutch universities are now all collaborating to build state-of-the-art instruments for La Palma, whereas previously their efforts were much more scattered.

As for ESO, which the Netherlands launched (the United Kingdom does not belong), "it has had a long, slow, start partly because of the remoteness of the place (the telescopes are at La Silla in Chile), partly the trouble of having many European nations working together". But according to van der Laan La Silla is already "a real state-of-the-art observatory, a fantastic observatory". "More and more" it produces the astronomy that it should.

ESO was born in Leiden: Oort called a meeting of the half-dozen most prestigious senior astronomers in Europe, with the idea of collaboration, and the result was the launching of ESO.

Van der Laan would like to extend Dutch cooperation with Britain and ESO. He would like to see Britain and ESO get together, for the later 1990s, to build the next generation telescope. It would be a $50-100 million telescope, very important as a complement to the Space Telescope "and much cheaper. The total cost of the Space Telescope is now estimated to be $1,300 million, so the next generation telescope on the ground in 15 million class will cost only one tenth as much and will be astronomically just as important (in combination with the space telescope). "Since we are partners of the UK and members of ESO, we'd be happy to be a catalyst" to such an agreement, said van der Laan. □

---

laboratories in Holland (such as Philips, see page 501), with which links have been weakening over the past few years.

Ten or twenty years ago it was obvious that there was a healthy job market in Dutch industry, so people in universities were often inclined to do work that was relevant, says van Lieshout. Also the companies toured round the universities looking for talent. "So as I put it there was a lot of *contact* research but not a lot of *contract* research." For the past five years there has been less of a market for academics. There was a period when the universities took a dislike to industry; and now multinationals no longer seek to do all their research in Holland. So the links have weakened "and we must be very careful that they don't get weaker."

Beyond mere finance, ZWO is expecting a re-structuring of its responsibilities and management, in a bill with which ZWO is not entirely happy. But the draft law does give ZWO the right to do applied research, a right it has sought for years. A small, young organization (STW) that now supports applied research in the universities will come under the ZWO wing making one broader-based institution.

Why does ZWO want applied research? "Well first of all no-one organizes that properly." TNO (the big Dutch national applied research organization) works in its own institutes and not in the universities (except by occasional collaborations). But ZWO, on its foundation, was denied the right to do applied research because of the existence of TNO. "That was a mistake", says van Lieshout.

As for the rest of the ZWO restructuring proposals, all is not well. The government's proposal was submitted to ZWO, the Academic Council, the Royal Academy and the Council for Science Policy for comment. "But the government found the comments rather unexpected . . . strong and rather negative. Since then there has been silence."

The proposal is self-contradictory, claims van Lieshout. First, the government announced it wished to step back and not be directly involved with ZWO, while yet retaining some influence. But in the government's detailed proposals, influence increases. Van Lieshout is happy to accept influence "if there's open dialogue between us; it's OK for a scientist to take up a slightly different line of research that's more interesting to government but just as interesting to science."

Present government influence take the form of an official representative of the government on the ZWO board. He has right of veto; but he never exercises it. In the proposed reform, the government superficially appears to want less, no more than an observer on the board. Would this not reduce their influence? Said a ZWO man "They want to have their influence without committing themselves in the board of the organization. They believe they have more power as an autonomous partner."

"If you want to make a caricature," says van Lieshout "ZWO will think about science all by itself, and will come up with a proposal; the government will think about it and come up with its own proposal, listening to parliament and to public opinion; and then the two opinions, generated under their own steam, will be confronted and we will come to a consensus."

"Well our idea is that that is not a good way of doing it, and that it's better to meet several times first on a lower level before you come to these views — and only then confront. But the government thinks it better to have the two lines separated and only confront at the end."

And in the detail of the proposal, it turns out that the minister will have to approve "every detail" of the budget. At present, the minister approves only the total sum.

"Of course there was discussion, but there was no official seal of approval on our allocation of the money. Now there will have to be." If the minister disagrees, ZWO may have to make a new budget.

As a further restriction, ZWO would have to consult the minister over any new international agreements. And on international relations ZWO has a rather independent point of view. ZWO is reluctant to enter into generalized international agreements, and it has only three: for exchanges with CNRS (France), CNR (Italy) and the Royal Society (Britain). ZWO has been offered exchange agreements with, for example, the US National Science Foundation, but has decided against them because, says van Lieshout "that kind of agreement we can have anyway . . . we can send people anywhere . . . there's no obstacle. And the universities also can do it on their own. So sometimes we don't even use up all the possibilities under our agreements because people can find their way without us."

However, when ZWO finds there is already international cooperation going on — say among astronomers — then it is willing to set up an international umbrella agreement that will make the collaboration official and "keep the money flowing". That is how ZWO reached an agreement with the British Science and Engineering Research Council (SERC) in astronomy and synchrotron radiation, to share the cost and use of British facilities, "only after it was quite clear that there was something workable, a concrete and very well defined project that would fulfil its aims." Says van Lieshout, "we're very much averse to starting an agreement just to see how it works out."

ZWO has also managed to avoid paying large international subscriptions. So it does not pay directly for membership of the European Molecular Biology Laboratory, although the question of continued membership "comes up all the time" in the Netherlands. Equally for CERN, the European organization for nuclear research in Geneva. ZWO does not pay the CERN subscription either, although "CERN was very much in the balance a year ago in the Netherlands . . . but the minister went there and was convinced".

The European Space Agency (ESA) is also outside the ZWO budget. So is the cost of scientific satellites (such as the infrared astronomical satellite IRAS), which is covered by the ministry of the economy. But there will be no more national Dutch research satellites, the minister said: there is not enough interest in industry, so Dutch space scientists must concentrate on ESA.

And they will do it through ZWO, as the Dutch space research institute, with a DFl 50 million budget for the building of instruments, has just been put under ZWO control. The move is "purely administrative", van Lieshout claims. "But now we have the opportunity — if we want to and after a few years — to shift the balance between space science and other fields of astronomy. □

Science policy

Half a minister better than none

AFTER a ten-year experiment with a science policy minister, the Netherlands now has none. Or perhaps a portion: in the present cabinet, the function has been combined with education in the post of minister of education and science, now held by the scourge of the Dutch universities, Dr Wim Deetman.

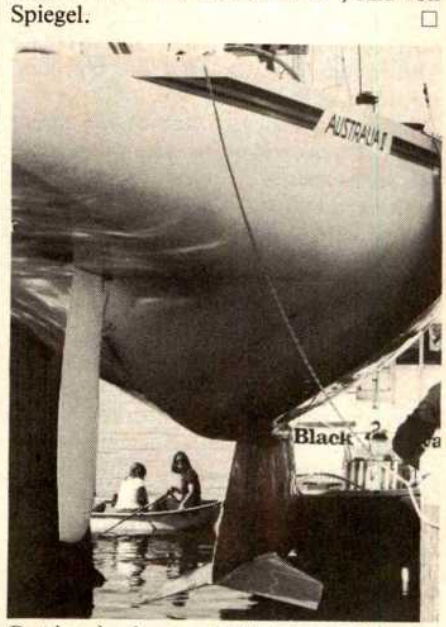
It was not a conscious decision to demote science policy — just a way of balancing the books of a delicate coalition of parties. But, says Mr von Spiegel, secretary-general of the directorate for science policy (which used to be the science policy ministry): "In Holland politicians are not interested in science."

Arguably as a result, and while Deetman was preoccupied with streamlining the universities, his captainless science policy

In Holland politicians are not interested in science. . .

directorate last year lost half its operational budget (originally DFl 70 million, som £17 million), a flexible fund for direct stimulus of research and development, and one of the directorate's most cherished instruments. (Otherwise it merely coordinates budgets under the control of other departments and advises on science policy.)

The loss occurred in a split which gave the directorate's work in "technology policy" to a new office in the ministry of economic affairs (which deals with industry). The new office also took on 10 of the policy staff. Thus von Spiegel and the remainder of his team find themselves rather exposed and isolated. And not only is the directorate preyed upon by the ministry of economic affairs, it is also at odds with the more bureaucratic department of eduction with which it is now combined. (The education department insists, in particular, on university autonomy, and even in the recent cuts largely allowed the universities to decide for themselves what to cut and what to defend. The science policy department style might have been different, but it was not allowed to play a significant part in the excercise.)



The science policy department is therefore being forced back into a more reflective role: "We will be less busy with operational tasks, with execution, than before", says Tindemans. The directorate will concern itself with the long-term rather than the short. But it retains its powers to coordinate budgets, and the minister of education and science is able to use the department to establish science and technology policies that cut across departmental boundaries — such as information technology, where the department has recently established a major new government action. That is a subject "of very broad importance", says Tindemans, bearing on the economy, education, health, public policy, and administration. Hence it made sense to give the definition of an informatics policy to the science policy directorate.

The directorate's DFl 300–500 (£75–125 million) informatics plan makes proposals for the expansion of informatics education (at all levels); offers funds for research, especially in software, and for applications — for example the computerization of Dutch records of physical infrastructure (telephones, cabling, pipes and so on). It also deals with networking and "task differentiation" (somewhat difficult in Holland) between big centres and small ones, involving the introduction of big computers like Cray 1s and Cyber 205s, where Holland has little experience; and deals with the transfer of academic expertise to industry. The acceptance of this report has been a science policy directorate success.

Also, the directorate retains control of the applied research council, TNO.

Intervention on departmental budgets and policy "will take more of our time in the future", Tindemans cliams. But before the departments quake in their shoes von Spiegel's view is that such intervention would prove very difficult.

The directorate is also managing an exercise to raise efficiency, and so cut spending, in some 60 government research institutes. Universities are included, but only as a point of reference. "We are looking at staffing and management of the centres" said Tindemans, in order to have an impact on the government budget for 1985. The savings are to come to DFl 130 million (£32 million) or about 5 per cent of the budget, less than the 10 per cent asked of the universities. "We think we can do it", said von Spiegel. □

Dutch technology was behind the revolutionary design for the hull of Australia II, which took the Americas Cup from the United States last year.

Biotechnology

Ambition and a track record

THE Netherlands is planning to make an "explosive impact" on biotechnology within the next couple of years. And they may well do so, not because Dutch companies can lay claim to the world's first genetically engineered vaccine (for pig and cow diarrhoea), and the first monoclonal diagnostic kit (which they can) but rather because the whole of biotechnical Holland is now, as one biotechnologist puts it, "in the start position".

The keys are context, and scale. First, Dutch biotechnology is forming within a coherent, flexible, apolitical, imaginative and believable national "strategy" (to call it a plan would make it sound too centralized and deterministic), in which basic research has a firm place. Second, although in a larger country such scheming can fail through excessive scale and, in particular, poor communication with industry, Holland is small enough that it really has a good chance of creating "The Netherlands Ltd". (History and geography have made cooperation natural to the Dutch.)

The strategy is the effort of a small group of biologists and industrialists, the national advisory committee on biotechnology, which has been giving direct advice to the Dutch cabinet. Its chairman, the most unacademic of academics Professor R.A. Schilperoort, plant geneticist of the University of Leiden, says the committee will wind up in May 1985, its work complete. The first real marketable products will emerge from the committee's Netherlands Ltd, through the big companies, within one or two years, Schilperoort believes. One of the major product areas will be in waste-water treatment, he expects.

From a practical point of view a university can't keep secrets . . .

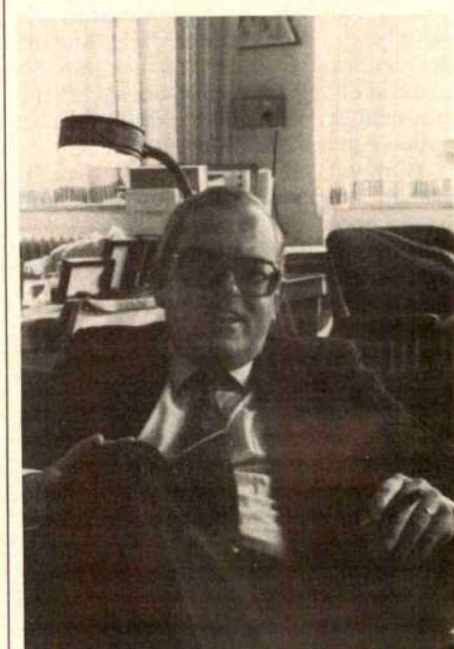
The committee has asked the big Dutch industries in the area (including Shell, Gist Brocades and Unilever) what research they would like to be done in Holland, and who they would like to do it. "All the companies are showing great interest. It's very delicate — companies like to be very confidential." But through individual, one-to-one conversations largely with Schilperoort's aide, who has signed a secrecy agreement, the advisory committee has got to know, at least in outline, all the Dutch companies' plans in biotechnology. This makes sensible strategic planning on a national scale a reality — whereas in France, for example, similar moves by the socialist government were met largely by non-cooperation from industry.

One problem has been the predominance of projects initiated by scientists rather than technologists, but there are moves to change this. The idea, Schilperoort explains, is to orientate university and government laboratory research "a little bit more to the market." University research may be as fundamental as scientists wish but "It shouldn't conflict with research in industry . . . we want to make it a source of results and people."

The committee does not want to create a biotechnology centre, believing that such places grow "sleepy". "Instead we make centres on certain themes, which have to compete all the time for funds." Thus the committee has somewhat by-passed the national applied research organization, TNO, which might on the face of it have been the focus of the biotechnology programme.

"TNO got a substantial part of our money, we have stimulated their programme in biotechnology, but they will have to do better if they want to get more . . . . It's grown too big . . . it's surprising . . . TNO was thought to be more commercially oriented than the universities . . .".

On international collaboration in biotechnology, the committee has an unusual, Europeanist attitude. "We like to collaborate in areas in which we are strong. So we've chosen three areas for collaboration: agriculture, waste treatment and pollution, and process technology. It doesn't make sense to collaborate from weakness. This is nationalistic. Collaborating from strength then we have a chance to be a strong continent. If we only act at weak points we will never be strong!" This, says Schilperoort, "is our signal to Europe". Bilaterally, the Netherlands is making plans with Switzerland and Germany, and is in discussion with France and the United Kingdom.



But back home, how far will this programme protect basic biology in the Netherlands against university cuts? "We are quite successful . . . there are really severe cuts, but from the money we have now we can support a lot of research." The committee itself has DFl 80 million to spend this year, and there is another DFl 30 million to be granted through a special priority-area committee. "We are making corrections to the cuts in the area of biotechnology."

And Schilperoort, who has had a strong personal influence on the development of the Dutch biotechnology programme, believes in basic research: "Our basic philosophy is that we need excellent, well-organized basic research — otherwise you are out . . . . It's very important to stimulate the creativity and originality of fundamental scientists, because you can't predict what they will find; we should only say, why not try working on organisms a little bit different from *E. coli* and see how far you can go . . .".

As for posts — "that's very important" — the committee would like to create university positions, in collaboration with the ministry of education; but only in the areas that will underpin industry's priorities.

There should be no secrecy in the universities, the committee believes. Fundamental research should be open research, says Schilperoort, both on principle and in practise. "You can't oblige a member of a university to sign a secrecy agreement . . . who will pay the money if he is sued? . . . from a practical point of view a university can't keep secrets."

But this is where the government applied research centres, like TNO, can come in. There, there are no problems of secrecy. So industry could transfer a successful, basic university project to the applied centres for development. "And we are thinking about how to set up small companies, seeing what mistakes we can avoid . . .". In the small entrepreneurial companies established abroad, market research has often been weak, they have begun without clients, and many companies will just fade away.

Chairman of the national committee, R.A. Schilperoort.

The Dutch programme is coming after the first wave of biotechnical excitement, but this very fact may give it an edge. There are many markets left, Schilperpoort believes. And it is the large companies which will lead the way. And they are prepared, having taken the biggest, most expensive scale-up steps — "much more expensive than a small amount of research". For example, Shell and Gist Brocades have created a joint, DFl 300 million, biotechnology laboratory.

Such things, plus good links with the universities, will create the Netherlands biotechnology enterprise. "Our Dutch industry is prepared . . . . They have good projects already and there needs to be a good, continuous, realistic flow . . .". And that, the committee is creating. □

Philips

Too big for a cautious Europe

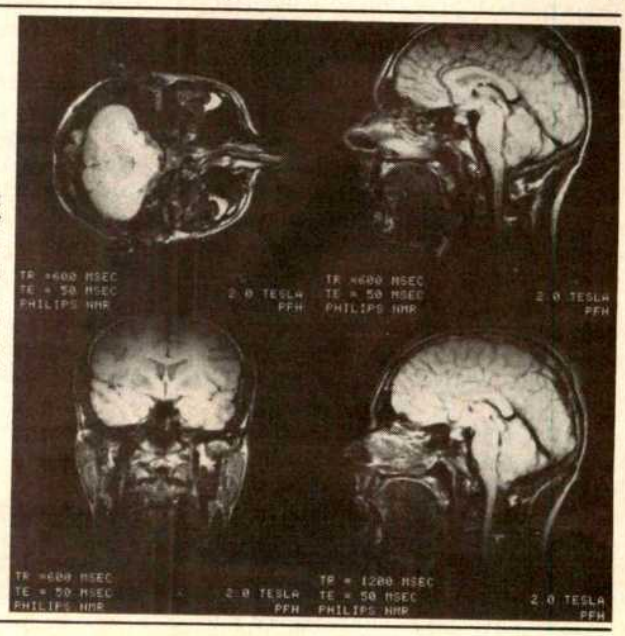
By far the largest research organization in the Netherlands is not public but private: the 2,000-strong Eindhoven laboratory of Philips, the electrical equipment multinational. And beyond Eindhoven, Philips, the maker of the technically brilliant but in marketing terms unsuccessful Laservision, the silver disk, also employs a further 2,000 researchers overseas in England, France, Germany, Belgium and the United States.

Philips' research budget of DFl 500 million (£125 million) is more than double that of the Dutch national research council (ZWO). Its development budget is DFl 1,500 million (£750 million), supporting a product range that began with light bulbs and now covers almost everything electrical outside power engineering. The company is also the biggest employer in the Netherlands. Some 22 per cent of its employees are Dutch — but only 7 per cent of its sales. Eleven of its 12 divisions are managed from Holland, but its directors see the company as primarily European, with a quarter of its sales, half the factories, and two-thirds of its employees in Europe.

Philips' greatest single research strength is in materials, claims Philips vice-president for research Dr A.E. Pannenborg. The original lamp research was the investigation of materials under extreme conditions. From there Philips invented ferrites, had a flying start in transistors, works now in ceramics, metals, glass, fluorescent materials, semiconductors. In fact, breadth is one of Philips' greatest strengths — the development of Laservision embraced lithography, precision mechanics, optical technology, servotechnology, plastics and more. But yet, Philips is broadening still, by setting up a joint venture with the American communications giant AT&T on digital switching, aiming first at the European market. The objective: economies of scale in the development of equipment.

In telecommunications Philips' markets were not big enough. Inevitably, perhaps, the company has done well in the Netherlands, "and we've filled Saudi Arabia to the point they've got telephones on every palm tree", says Pannenborg, . Philips also has a market in the old Dutch colony of Indonesia and a modest position in Peru. "But if you add up our markets, we can't bear the costs. We were very happy that AT&T was available. We are complementary." AT&T has marketing in the United States, and Philips has competence in the worldwide CCITT standards, which the enormous American market has previously been able to ignore.

Cooperation with other companies in Europe, however, is developing only slowly. But the European Commission exercise on coordinating European research on information technology, Esprit, was a big step forward.



On academic cooperation, Philips' research works almost independently of the Dutch universities — except for staff, which are recruited young, spend 5–10 years in the research laboratories and then move into the product divisions. The average age in the Eindhoven laboratory is rising a little, but there is a firm policy of moving people on, in order to be able to recruit up to 200 graduates a year.

Nevertheless, Philips does not go in for contract research with the universities, or other outside laboratories in Holland. There were more links before the university "revolution" of 1968–69 but then the company pulled back — as did the universities at horror in involvement in matters commercial — and since then the two sides have been drifting further apart. There is now a new climate of willingness in the universities to cooperate, but, says Pannenborg, "The quality of university science is fair but not particularly good in this country." The "egalitarian wave" of 1968–69 led to a reluctance to develop centres of excellence. So there are very few places in Holland with which Philips would really like to cooperate. On the other hand, in computer aided design Philips has "intense and effective cooperation" with the Flemish university of Louvain over the border in Belgium.

. . . most of our competitors have died in the struggle. . .

But despite its arguably world-class research effort, which to some extent justifies its disdain of Dutch university research, Philips profits remain, to quote vice-president Pannenborg, "unacceptably low". The problem, he says, is less with Philips than with the conservative, unadventurous European customers. If Philips in Europe is healthy, says Pannenborg, then Philips is healthy worldwide. But in Europe "we lack the leading-edge customer. It makes life damned difficult!" Thus the true strength of America's Silicon Valley, claims Pannenborg, is not that there are so many highly competent silicon foundries, but that these foundries "are embedded in a place where you have the leading computer manufacturers, the leading weapons systems people, the leading automation people of the world who *suck* the products out of these foundries". By contrast the weakness of Europe is the cautious, reticent, non-innovative, wait-and-see attitude of the customer, whether institutional or individual. Nevertheless "if you look around Europe, we've done quite well. In fact most of our competitors have died in the struggle."

However, according to some outside observers Philips also suffers from a number of structural problems, the first being the separation between the research and product divisions which (say the critics) has allowed research to get carried away with its own ideas. Philips claims to have cured that problem recently by introducing more interaction. And some in Philips will admit that, perhaps, the quality of Philips' marketing does not match up with the quality of its research. Philips could do with a strengthening of "strategic marketing" — the kind of thing that might have taken into account at an early stage that the consumer was not going to be too interested in a video disk (Laservision) that could play but not record, however beautiful the technology, when it came on the market long after recordable videotape, and at a higher price. Philips is now working on home recording onto the disks, but there is a problem of stability of the record, and marketing tactics are now having to shift to the much smaller "professional" market. But perhaps, with a little more awareness of real markets, and a little less complaining about the backwardness of European consumers, Philips still has a bright future. □

THESE images of an adult head are another product of the Philips research effort. From the laboratories in Hamburg, West Germany, they represent the first 2-tesla images of the human head by nuclear magnetic resonance imaging.

Belgium

Universities poor and divided

UNIVERSITIES everywhere are struggling for money and posts. But the six full Belgian universities can claim a certain notoriety — as an extreme case.

The chief administrator of the national research council (FNRS) claimed recently that Dutch researchers have twice as much money for research as Belgian, and the French four times as much, and although "money for research" was left undefined, figures do show, for example, that Belgian university research funds, per undergraduate student taught, are less than half those in the Netherlands (see Table 4, page 493).

The best basic research survives, much of it only by shifting emphasis heavily towards the applied sciences. The national government has been supporting applied science with fashionable zeal — although some responsibility for applied science has been transferred to regional governments established in 1980. (One of these, Flanders, is taking up the task with particular excitement, with Wallonia a close second.) But in ten years there will be no new science in Belgium to apply, say many voices, as the basic sciences are more and more neglected . . . .

Another course for certain lucky groups is to hang on to an unreliable lifeline thrown by the late prime minister Théo LeFévre back in 1970. This is a prime-ministerial fund for "excellence", the "concerted action" programme (the "concert" is with the government). The programme, as conceived by LeFévre, offered temporary relief to important groups whose costs were rising too fast for the standard funding mechanism to cope. (Their budgets — even those of FNRS — are keyed to student numbers.) But temporary has become permanent, and many important groups now rely on concerted action funds to do their basic work; while, nevertheless, the continuance and allocation of the funds is unpredictably tied to government policy.

Yet despite the troubles, Belgian science is strong: molecular biology, in particular, has a worldwide reputation, and can boast two Nobel Prize winners since the Second World War (of which Christian de Duve, the discoverer of lysosomes, is still active with his international Institute of Cellular Pathology in Brussels). Physicist Ilya Prigogine is another renowned and energetic Belgian Nobel Prize winner; he also works in Brussels.

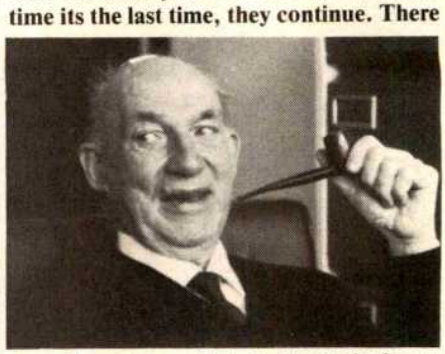
But there must be a question as to whether such success could ever recur in present conditions. The big slide began in 1976, when the Belgian Government began to seek savings on university spending. At the University of Ghent, for example, 20 years ago salaries accounted for only 70 per cent of income, with the remainder used for research. (This was the so-called "first stream" of research support, distributed within the university by a local committee as in Holland.) But now some 90 per cent of the budget goes in salaries; so the flow in the first stream has slowed by a factor of three, to a mere trickle. Said Professor Jean Brachet, biologist at the Free University of Brussels, "I was once on a committee here distributing money for apparatus. But now I'm told it's almost useless to go to the meeting because there's so little money to distribute."

As for posts, the universities face, since last year, a demand to make 10 per cent cuts in academic staff over the next seven years. According to Ghent plant geneticist Professor Marc van Montagu, in practice his faculty has made no permanent appointments at all for the past two years. (The same is true at the Catholic University of Louvain-la-Neuve, according to the dean of science there.) Says van Montagu: "Now we have to handle the university like a high school: if we're short of a biologist to teach a course we have to ask a chemistry teacher to do it: we're reaching that level... The problem of jobs is hitting professors as much as assistants."

And to add to their relative poverty, the universities suffer a special Belgian pain. Like all Belgian institutions, they face increasing rifts and tensions between the Dutch-speaking north (Flanders) and the French-speaking south (Wallonia). Four of the universities even make bad worse, as they suffer from a further historic division between Catholic and non-Catholic. As a result Belgian academic funding is all but divided into four equal pieces. Certainly it is divided in two — Flemish and Walloon — thus hindering the selective distribution of meagre resources. An exercise such as in the Netherlands, where the universities were "concentrated", departments closed, and people sacked — according to what were at least nominally judgements of quality — would be inconceivable in Belgium, as it would be far too inflammatory in regional or denominational terms.

Further, while the mobility of academic staff throughout Europe is bad, mobility in Belgium is nil. A budding researcher who arrives at a university at 18 is likely to stay there for life — if he or she is lucky enough to get a post.

But to take a somewhat Machiavellian view, there is one good side to all this: the near-anarchy has allowed certain pragmatic researcher-princes to establish their city-states. Just as princes raise taxes wherever they have influence, so do these researcher-princes raise funds; and the luckiest, most pragmatic and most persuasive may thus have been able to accumulate a greater relative income than they would have done if policy were more centrally controlled. Thus there is a greater presence in Belgium of centres of excellence than there is in neighbouring democratic Holland. □



Actions concertées — lifeline of the strong

IN the 1960s Belgian basic research was funded well enough through the university budget with grants from the national research council (FNRS). But towards the end of the decade molecular biology, and some other sciences, outgrew these funds — and Prime Minister Théo LeFévre started a fund, dubbed "*actions concertées*" or "concerted actions".

The grants, beginning in 1970, were substantial and highly selective: the aim was to support excellence and only the strongest groups received them. They lasted five years at a time and could reach BF 10 million a year (£125,000), compared with university funds which were rarely more than a tenth of that for supplies. One microelectronics laboratory — at the Catholic University of Leuven — increased its size tenfold in this period.

But will they last? Staff at a key laboratory in molecular biology, at Rhode St Genèse near Brussels, founded by Professor Jean Brachet, have their fears. Brachet has retired, and now the contracts are decreasing; "and we are told that in two years they will finish". According to Brachet himself "the *action concertée* has not been the main source of funding for our applied projects, but in a field like embryology, when the *action concertée* is finished it's the end."

However, Brachet is not too perturbed: the science policy programming office of the prime minister that distributes the grants "say they want new projects — but I've been involved before in helping distribute the money and while they say every time its the last time, they continue. There are not so many groups of this size and quality in the country."

Jean Brachet — optimistic despite budgetary pressures

Incidentially, Brachet also met the famous LeFévre, who many in Belgium regard as having saved basic science. "He realized", says Brachet, "that to get people into research of any kind was an investment for the country, even if in the long run he was interested in boosting applied research. □

Industrial research council

Basic PhDs recipe for success

IRSIA, the Belgian national council for the stimulation of research in industry and agriculture, is a good deal more than it might seem from its title. Contrary to expectation — given Belgium's current political attachment to applied research — IRSIA plays an important role in maintaining the fundamental sciences.

Universities depend on IRSIA for research studentships, even in the most basic sciences. (IRSIA merely limits the field to "science", in the English sense of the word.) The council provides 600 such grants a year, awarded on the basis of interviews, compared with the mere 100 from the national (basic) research council, FNRS, which are offered to those with the best marks in first-degree examinations, and cover all academic disciplines.

IRSIA conducts 900 interviews for the studentships at its headquarters in Brussels every year. Apart from university assistantships, which are few, IRSIA claims to cover 80–90 per cent of students working seriously for a PhD.

But why should an applied research council take on such a job? It seems the object — which dates back to the council's post-war foundation — is to provide research-trained scientific manpower for industry. And IRSIA's view is that 'research' requires a certain state of mind, a certain approach, that must be learned before a student considers application.

It is possible to do a PhD in Belgium with grants paid neither by IRSIA nor by FNRS, but by industry. But, says IRSIA's director Dr J. van Keymeulen surprisingly: "this is not the best way to do it: then you have to produce some applied results . . . but a PhD is something else . . . an education".

All IRSIA asks of a professor proposing a candidate for an IRSIA studentship is that he or she must guarantee that the subject will lead to a doctorate. IRSIA claims to take no control over the subject matter of the PhDs, although this occasionally requires a little heart-searching. For example "we asked ourselves several times what the students of Professor Prigogine [Nobel Prize winner in irreversible thermodynamics] would do after that training in theoretical physics. But none of his ex-students is unemployed! So their training was very good because their scientific environment was good — not only Professor Prigogine but his co-workers also. I don't say the subject is of no interest — but it is important on the second level. The environment in which you live — that gives you your training."

Nevertheless, the system might not have survived if the studentships had not also acted as IRSIA's antennae in the university system. "They give us a very good idea what is going on in the university laboratories". They account for only 10 per cent of IRSIA's turnover; but the rest consists of various forms of aid for industrial and agricultural research, much of which finds its way back through joint projects into the university system. There, the studentships help IRSIA management keep in touch with who's who and what are present research trends.

But is all this not just rationalization of a historical circumstance, that the university PhD system began to depend on IRSIA grants? Is it truly a policy? "That takes us back to 1946", explains van Keymeulen "when IRSIA was created out of the FNRS. FNRS's job was mainly to sustain professors. . . We aimed to sustain projects in industry and agriculture. And we gave scholarships. (We started with 10.) We needed the manpower: Belgium was really underdeveloped in research and development. All we had was universities. The IRSIA idea was to create something in industry — and we needed the people." This historic role has become bigger and bigger.

But was it never the role of FNRS? "No. They selected the very best people. . . the candidates for Nobel Prizes. We had another group. We said we wanted good people, who could give good service to industry. That was our role." □

New studentships plus job in industry

THEY are being dubbed the "Maystadt boys" — although it is an equal opportunity offer. Science and budget minister Philippe Maystadt has established a budget of BF 900 million (£11 million) intended for younger students, just out of university (or having just finished a PhD), to work in fundamental research and learn techniques that would or could lead to industrial application.

Each grant lasts a maximum of three years. But if the person is hired by industry within that period, the laboratory has the right to hire someone new, again for three years. If the person is not hired by industry, they lose that position.

These are not postdoctorates — nor PhDs, although it is not excluded that a doctorate could be earned — but research training exercises lasting 1–3 years. Students on the biotechnical part of the programme, for example, have to learn the techniques of the kinetics of immobilized enzymes, or cloning or other techniques.

"It is a very intelligent programme", said one laboratory director just after a telephone call telling him he will have five of the posts to distribute. "It's really useful, as you will be able to get on with your own work on the condition that you give training to someone in basic techniques." And Maystadt's project, in fact, covers a lot more than biotechnology — a whole range of scientifically and technologically interesting fields.

However, not everyone is so pleased with the idea. The students must be young — they must never have had a job before. "And", said another recipient "in every contract we get nowadays it says that any result that derives directly or indirectly from the work will belong to the Belgian state. These people get BF 100,000 a year, about a third of what they need to work in genetic engineering, just for materials, so you have to find another two thirds. But each source of money says that everything that will be done belongs to me. . . And in some cases in these grants they forbid publication."

"But — these are 200 positions, and that must be basically good. . ." □

Research opportunities

No room for manoeuvre

IT is still possible to do a PhD in Belgium, although the number of grants is falling. But at the postdoctoral level? The constant refrain is that there are almost no postdocs in Belgium.

Universities can create permanent assistantships, but a law of 1976 restricted the number to below 40 per cent of the total number of assistants; and most universities have already exceeded that figure. "We have had no new posts at Louvain-la-Neuve for two years — at any level, in any faculty", according to Louvain-la-Neuve's dean of science, Pierre Macq.

At the same time, fewer students are interested in staying on for a PhD. For example, in 1983 a dozen new graduates from Louvain-la-Neuve sought research studentships from the national research council, FNRS; but in 1984 there are only four applicants. "It's a general situation: people don't believe in the future. The funds are going down but the demand is going down also", says Macq.

In Belgium, there is nothing like the French CNRS, or the British research councils, to provide postdoctoral posts outside the university system. FNRS has no laboratories. It has a few coveted permanent posts, but these — intended to be stop-gaps but already 12 years old — are almost vanishingly few and offer no career structure. To compare with the French CNRS, there is no level of 'director of research' which "makes life 'uneasy' for an ambitious young scientist", says Brachet.

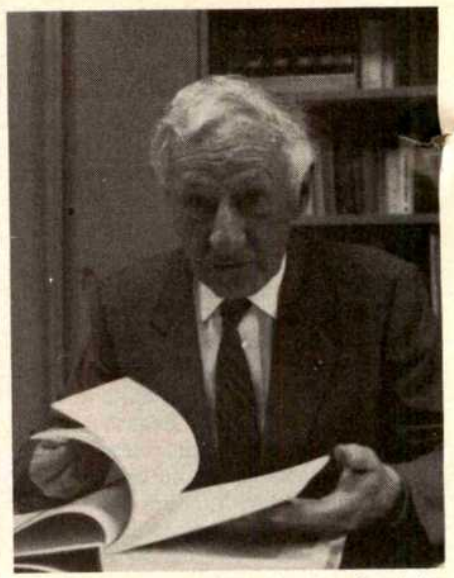
Even so the competition is "incredible" for these positions. Says Professor Nicolas Glansdorff, a Brussels microbiologist "It has become almost impossible for a good — let's not say excellent — researcher to get one of these posts. If you look at the curri-

culum vitae of the winners you would say that most of them should be professors — and more than that for some of them. The problem is that in Belgium where the scientific level is quite good, we have each year maybe 15 people who've published in *Nature* and *Cell* and *PNAS* competing for one post! It's completely crazy."

So the unlucky ones in Glansdorff's laboratory — some of them in their 40s — live year by year, go on unemployment benefit for a time, come back again — "it's really traumatic for them".

At FNRS, these life fellowships are described as "the *nec plus ultra*". Yet they were introduced only as a 'parking lot' when university posts began to tighten up in the early 1970s. It was intended that universities would absorb them when the situation eased.

But the situation never did ease. "Now we have a completely new and very difficult situation", says Brussels engineering professor André Jaumotte, who was FNRS president when the posts were created. "FNRS has reached the maximum number of posts it can fill, limited by its budget. This year, in the University of Brussels we have no more than four posts of our own to fill; at FNRS there are three posts on the French side in all subjects. We are blocked at FNRS . . . at university . . . and we have the economic crisis."



"It's very very difficult now to get a new man into research. . .", says Jaumotte.

The FNRS scheme began with ten Flemish and ten French posts, in all academic fields. Later it declined to seven Flemish and six French, because Jaumotte had imposed the sensible rule that if a university failed to give the fellowship holders a job, then they could not get any more such posts. FNRS had relied on the universities taking them up. It was not supposed to be a career position — but it has become one. In 1984 FNRS will have six Flemish and three French posts to offer — plus another two or three on the Flemish side where some universities are expected to give some existing holders posts. The uneven division between the regions is a consequence of the fact that the Flemish universities are younger and still growing.

Fifteen people who've published in *Nature, Cell* and *PNAS* competing for one post . . . it's crazy

Inevitably, with so few posts to offer, particularly on the French side, intrigue begins to play an important role in decision-making. Says Brachet "When the last FNRS director died, they didn't fill his post. So the council is now headed year after year by the rectors of the universities. There should be more independence, because finally it's the rector in charge at the time who decides."

"For example when we try to get a researcher a permanent post, we do what we can in the committees, there are fights and so on, but there are more than 20 committees, one for each field, each proposing candidates — and finally the rector in charge makes the selection in an arbitrary way. So you know that if your man has been classed first, the great thing is to work on the rector, and convince him that your man is the most excellent!"

André Jamotte, the man who introduced the "parking lot" posts.

To put rough figures on it, FNRS has a five-to-one surplus of demand over supply for research studentships; and for permanent positions ten to one. The Flemish-side administrator of FNRS considers that FNRS could double the number of research studentships without any loss in quality. "For the permanent jobs it's awful. We could take 80 per cent of the applicants."

And without posts in Belgium, some of the country's best young scientists are leaving — particularly from the French region to France, where posts and funds are much easier to come by. Said one Walloon group leader: "Two of my students are now *chef de service* at the Institute Pasteur in Paris, one is a director of the French genetic engineering company Transgène, others are in Lille, Montpelier . . . There really is a brain drain."

Even some senior people are leaving — like plant geneticist Professor Jeff Schell who was nominated director of a Max Planck institute in Cologne and now comes in to his Ghent laboratory one day a week — "this is a part-time brain drain!" said a colleague.

Another example of the problem is a researcher who as a student took a joint best first class degree in the Free University of Brussels. He was lucky enough to win a national prize for his thesis, which got him a permanent FNRS fellowship. He has been a year at the Massachusetts Institute of Technology, two years at Yale, and then came back. He might have expected a professorship — but the place he might have taken at the university, shortly to be vacated by a retiring professor, is to be abolished to save money. Anyway he would face the poor funding of science in Belgium. Now he has been asked by the French Institut Pasteur (Lille) to work in France. He would be able to take with him

In or out — a "scandal" over EMBO

BELGIUM's position in the European Molecular Biology Organization (EMBO) and the laboratory (EMBL, in Heidelberg), is somewhat confused. The story begins with the Brussels biologist Professor Jean Brachet. A few years ago he was seeking to set up a national or international biological laboratory in Belgium, on behalf of Belgian biologists. He met resistance at every level, and "that's why I was among the first to think about EMBO". Brachet played an important role in the establishment of the organization. But amazingly, Belgium is still not an official member. And Belgium does not contribute to EMBL.

"What happened", says Brachet "was that after pressure from our Nobellists Claude and De Duve the government admitted that EMBO would be a good thing, but they said that since EMBO planned to have a laboratory, and Belgium did not want a part in it, they could not join". But they pay indirectly: they give the EMBO subscription to FNRS, which pays, but the Belgian state has no official place in the organization.

This leads to a diplomatic anomaly. There should be an official representative of every EMBO state on the EMBO council, but because Belgium does not have official membership, it has no such rights. Belgium sends the general secretary of FNRS, who is allowed to listen, but not to speak — the government, it seems, fears that becoming full members would mean coughing up for EMBL.

And despite the original reluctance to establish the laboratory, Belgium *does* use EMBL. "But we are really ashamed — we do not feel comfortable", says Brachets' successor Professor Renée Thomas. "EMBO treats us very generously, in the number of people from Belgium who are elected and so on — chosen on scientific grounds alone. We have young scientists going to EMBL and they treat us as if we gave the money. It's scandalous."

EMBO costs some BF 1–2 million, and it would be another BF 25 million for EMBL. "Greece pays; Finland pays; we don't. I asked Mme Dehaux, the director of the government science policy programming office: she said listen, "we haven't even contributed to CERN (the European nuclear physics research laboratory) for two years; why do you want us to contribute to EMBL?"

The CERN payments have now been made; EMBL is still waiting. □

three people for three years, with a permanent post for himself. "It shows people have been well-trained here, at least . . .", commented a colleague.

However, a senior official of FNRS, has a more sanguine view. "It's a very tough problem" he admits. "On a first look, you would say yes, there is a brain drain, in absolute numbers. But is the final output a brain drain? I know a lot of people who emigrated to the United Kingdom or the United States, who have professorships there, who are training Belgian students who come back and enter industry here — for example in solid state, bioengineering, molecular biology. There is a brain drain, but the effects may be positive in the long term." □

Research council

Strength through division?

THE Belgian national research council for basic research, FNRS, is divided in two, almost literally from top to bottom. Downstairs in its tall Brussels block sit two women, in identical uniforms, side-by-side in identical glass boxes. Above them are different signs: one reads "reception" in French, the other in Flemish. A visitor must be sure to speak to the right receptionist: the first will connect you only to the French side of the council, the second only to the Flemish. Money is divided just as automatically: according to a politically agree formula (called a key — Belgium has many keys), some 54 per cent of FNRS funds go to the Flemish side and 46 per cent to the French.

Crazy? No, says an ex-president of FNRS, engineer Professor André Jaumotte (who is also ex-rector of the French-side Free University of Brussels), this *a priori* division keeps political, regional conflict out of scientific discussions: given the key, "there is no possible argument about the budget, so you can discuss quality without complications." The system results in "some duplications . . . it's not perfect, but it's not so catastrophic".

The Flemish-side administrator of FNRS also backs the division: because it provides independent referees. "Our boards of referees are composed of ten scientists, five French, five Flemish. They advise as one body, but in two budgets. So, say, in discussion of a Flemish project, there are five French referees who are entirely independent; and vice versa.

In fact, says the administrator optimistically, "regional divisions are not worsening the problems of Belgium — they help find the solution! I'm quite sure of that . . . ". Belgium, geographically, is the south of the north and the north of the south. So, "two mentalities meet here . . . Here, in this very small country, Anglo-Saxon and Latin attitudes stimulate each other.

However, according to a Walloon biologist, the cultural division of FNRS spreads cash too thinly. "Instead of backing a good group in one subject on one side of the country, and a good group in something else on the other, everyone is trying to do the same thing — every sum is divided." This can mean constructive competition, though says the Flemish FNRS director.

The FNRS formula of 54 per cent to Flanders and 46 per cent to Wallonia is not fixed. It is based on the numbers of Belgian graduate students in the two regions, and it shifts as those numbers shift. The trend favours Flanders. In the 18–30 age range, 65 per cent are Flemish speakers and 45 per cent French, and university attendance is increasing in Flanders, whereas it has stabilized in Wallonia. So the balance is shifting further and further towards the Flemish. It will eventually stabilize at about 60/40, the Flemish administrator believes.

But these ratios are very new. A decade ago, before the key, the French side used to dominate. "For a long while all scientists spoke French, even in Flanders, and there were few Flemish students until after the Second World War", claims particle physicist Professor Pierre Macq, dean of science at the (Walloon) university of Louvain-la-Neuve. "So the Flemish demand for grants from FNRS was low; for example even in 1970 Flanders had only 30 per cent of all physics research in Belgium, although the population was 60 per cent Flemish."

But, Macq admits "it really was an anomaly". So, at the beginning of the 1970s, it was reasonable that the Belgian premier Théo LeFévre should determine to give new funds to Flemish fundamental research, without decreasing the French side, until the Flemish and the French sides were balanced. Only half the plan worked. The government established the key, which would give Flanders its fair share. But then

FNRS — cream but no cash

THE Belgian national research council (FNRS) has always aimed to provide for the cream of Belgian scientists, mostly through peer-reviewed grants and — for the past decade — through posts to be taken up in universities. It remains the best institution to which Belgian fundamental scientists can turn for peer-reviewed funds. But FNRS simply has too little money.

And FNRS funding has declined. The budget of FNRS and its "associated funds" for medical research (FRSM), and inter-university and interdisciplinary research (FRSC) fell by 5 per cent in real terms between 1979 and 1983. Over the same period the nuclear and particle physics budget (another associated fund dubbed IISN) fell 16 per cent (excluding international subscriptions).

Contrast this with the applied research council IRSIA, which enjoyed a real-terms rise of 20 per cent, and the whole state budget which rose 37 per cent!

So why has FNRS been neglected? In these political times in Belgium, one fact stands out. Since FNRS focuses on "quality" and peer-review, politicians have no power to control its actions. Political power over other sources — such as the prime-ministerial funds (the *actions concertées*), or national programmes (such as one on energy research) can be much greater and so FNRS is forgotten. That may be the real reason why the FNRS budget has been declining steadily.

Apart from posts, FNRS also gives small research grants to individual researchers — nominally from BF 50,000 (£625) to BF 1,000,000 (£12,500) for 1 to 3 years. The very maximum is BF 1 million for one year but such sums are rare. According to Brussels biologists the sum of BF 500,000 (£6,250) for a year would be "a big grant at FNRS. . . We got BF 50,000 for three years to work on the properties of a small parvovirus . . . which is very little money . . . with no personnel".

The budget for FNRS, excluding its associated funds, is BF 858 million (£11 million) in 1984. Nearly 85 per cent of this goes to studentships and fellowships. The associated foundations have around BF 2,000 million (£25 million) to play with. The funds of FNRS proper are tied to the university budget. By the 1971 university financing law, FNRS receives a precise 4.44 per cent of the running costs (excluding salaries) of the six complete universities. "I've no definite idea what the comparable figure would be in other countries" said an FNRS official "but it must be two or three times higher."

If FNRS were lucky enough to win a budget increase, how would it spend it? "Mostly on research students" said a Flemish-side official "to increase the quality and number of PhDs, for industry as well as university life. Second, to research contracts, to stimulate inter-university and interdisciplinary work." (The Belgian universities are very monolithic, and this would help to break the barriers.) "If the R in R&D has no basic component, then forget your applied, your development. We have to go back to basic research. This is not just special pleading. You must do the research, and train people — the PhDs — who will be able to go out to industry and come back to pick up these ideas."

"We really need double the money we have now. Otherwsie I fear for the future — not just for the universities, but for the people of Belgium . . .". □

came a budget crisis; and the FNRS budget was frozen.

There was no new money to pay for the new Flemish share; so since the key had been agreed, the government could do nothing but decrease the French funding to pay for the Flemish increase. So while all Belgian scientists have had to face constant or decreasing funding since 1977, in the French part the problem has been much worse, Macq claims. "The objective was admirable" says Macq "but the result in Wallonia was disaster".

Take fundamental nuclear and particle physics, for example. They are funded through the IISN research fund (an associated fund of FNRS). IISN funding of research in Wallonia fell 20 per cent in real terms between 1977 and 1983, says Macq, whereas Flanders saw a 24 per cent increase. In research council funds other than IISN, there was a net real decrease of 11.5 per cent on the French side from 1977 to 1982, but an increase of 1 per cent on the Flemish, according to Macq's calculations.

Macq also criticizes trends in the national fund for applied research, IRSIA. "The main goal of IRSIA in 1950 was to expand research fellowships in Belgium, because the number of PhDs was very low before and after the war, except in chemistry. But between 1977 and 1982 IRSIA has increased 28 per cent in the industrial sector and 13 per cent in agriculture, yet decreased 6 per cent in fellowships."

"When you see all these numbers — you see there is something wrong in Belgium."

Biotechnology

Cooperation *can* succeed

BELGIUM is strong in basic molecular biology. It also has some strong pharmaceutical and chemicals companies. The two are getting together under the wing of IRSIA, Belgium's applied research council, in an innovative, unified scheme which breaks new ground for IRSIA, which normally puts a single company together with a single university group when dealing with universities.

Three years ago the council faced a rash of proposals from companies that were keen to start up in biotechnology. But they all wanted to associate with the same laboratories — the good laboratories. They had seen, says IRSIA advisor Dr W. Degriek, that "something was going on in the universities" and they wanted to join in. "They all needed to take the first step on the learning curve, and they counted on the universities for help."

So IRSIA called them in and told them to take the first steps together. "We said: you must all do the same first phase, and we will bring in only the best specialists from the universities — this will be cheaper and better than the individual projects you've proposed and you will all profit from it."

IRSIA did not restrict the programme to the companies that had applied, but launched a big campaign and added others. The universities then made a global proposal covering most of the companies' needs. A "biotechnology club", now with 33 member companies, was established. Members can introduce their own projects, but they have to show some "solidarity" with the ongoing, "more or less basic" research, preparing the future, training young people in that area.

"So we realized two goals in the same formula: we avoided overlap, and we created a new and larger movement", said Degriek. IRSIA has been pleased with the results and has repeated the exercise in five areas of biotechnology: in fermentation, monoclonal antibodies, genetic engineering, protein engineering, and production of methane by immobilized enzymes.

Research directions are guided by three-monthly meetings with industry, and IRSIA already has two patents out of "really high-level research."

IRSIA, excited by its success, sees this as a new system of support, which they could apply elsewhere. They call it the "common trunk" — from which branch specific company projects. "It works really well for brand new technologies, where everyone works really well for brand new technologies, where everyone still has to learn, and there is no competition yet."

Royalties from patents are to be distributed through contracts on which IRSIA claims to have done "marvellous work". The contracts are very complex, because IRSIA has had to link the interests of multinationals to those of very small Belgian companies that have completely different markets and possibilities. "You have to marry them somehow. We think that's been one of the successes, having been able to define a contract linking up that very inhomogeneous club."

IRSIA started one project in fermentation in 1981; the formula became more precise in 1982; and the last project, in protein engineering, was added at the end of 1983. There are now three "common trunks" in robotics, two in speech processing, and one in artificial intelligence.

"This is really where we really are bringing the universities in . . . it's never been so clearcut until now . . . before, either a whole industrial sector had to agree on a single project, or it was with one company and therefore rather short-term. Now all the "common trunk" meetings are very active, there's a big exchange of ideas, and the professors have really good support. They get posts, new specialists in their laboratories for a rather long period, not just one or two years."

"We really want", said Degriek "to make the building blocks for the next generation". □

Science's crisis

The logic of application

To understand Belgium one needs perspective. A source of perspective is the Belgian national council for science policy, CNPS, which has just prepared its most important document yet — a set of proposals for solving the Belgian "crisis" in science (it is not too strong to call it that) over the next ten years.

But every perspective implies a viewpoint; and some leading fundamental scientists in Belgium consider that CNPS is too beholden to industry, and too favourable to applied science, for the health of basic research. As circumstantial evidence, the complainants cite an attempt to set up a council of the "scientific aristocracy", including Nobel Prize winners Christian de Duve and Ilya Prigogine, to advise CNPS on the needs of basic scientists in Belgium. This committee of the greats was allowed to die after a two-year trial.

As a result, CNPS — and its president, Professor R. van Geen, ex-rector of the Flemish free university of Brussels and an applied physicist — has become the only effective scientific voice in or near the Belgian national government. So if CNPS were blessed, it would be significant. Moreover, CNPS wields its influence over a government already inclined to think that basic research can look after itself.

However, the accusation does not quite hold up: van Geen and his CNPS are not going to be willing scapegoats for the troubles of basic science in Belgium, although they certainly put an emphasis on application in their 10-year proposals.

So what of the composition of CNPS? With 34 members, it is designed to cover all interests in science and technology, and it must also cope with the linguistic divisions

. . . every researcher cannot do whatever he or she wants . . .

in Belgium. Those apart, CNPS represents four groups: the research establishment (rectors of universities and directors of research); the grass roots of research (young researchers in universities, government laboratories and private industry); the leaders of industry, including banks, some big companies, some small ones (the capitalists, as van Geen puts it); and trade unions and cultural groups. This broad council advises the science policy minister Philippe Maystadt ("a very clever man", who is also government budget minister).

Unfortunately, at the time of writing the CNPS recommendations on policy for the next 10 years are unpublished, unavailable and politically sensitive because, says van Geen, of the "objective" fashion in which CNPS has treated the two communities problem. But he was prepared to talk about its broad outlines.

The first difficulty with Belgian science is

money, the report says. Government spending on science was cut dramatically in 1977, and there has been no recovery. The universities were especially hard hit by the 1977 cuts — "It's the Thatcher policy...". University budgets are still decreasing. "In three of the six universities, they've stopped taking the journal *Physical Review*! Which is unthinkable!".

The proportion of gross national product spent on research in Belgium is too low — at around 1.5 per cent (0.6 per cent by government, plus another 0.9 per cent by industry). Belgium is trailing in the government sector, as a result of cuts in government spending in the face of the economic crisis. But in its 10-year report CNPS argues that Belgium needs to make an effort "precisely because of the economic crisis, not in spite of it...". The greatest difficulty in Belgium is to get this point over: "politicians often consider that research is a luxury, a dispensable item".

Minister Maystadt recognizes the problem, says van Geen, and has a plan to raise the proportion to match other countries in five years. Plans can fail, of course, and in any case the emphasis in this new initiative remains on applied research projects.

But the result of present poverty is a brain drain: "We have very good universities and scientific education — and we're a country known all over world for the quality of its scientists. It's a pity that we can't support them here...".

The CNPS report, however, does do more than cry "more!". "Every researcher cannot do whatever he or she wants" says van Geen: "research today needs more than a pencil." So CNPS suggests there should be a *selective* policy in fundamental research. The policy should be based on finding a proper equilibrium between fundamental and applied research.

The selection would focus on "centres of excellence", which van Geen defines as "those places that have the people, the equipment, and where the science is relevant". The term "relevance", of course, implies selections; but other air can enter the CNPS system, as CNPS is also aware that such centres can age and atrophy. "If you only do science in centres of excellence, at some point you will have none", as their science becomes obsolete, says van Geen. "We have that today with the nuclear fission research centre at Mol. Thirty years ago it was at the frontier of physics, now it's rather out of date."

So as well as support for the centres of excellence, there must be money — "local" budgets, van Geen calls them — to stimulate "trial, background research". For example, van Geen says that Belgium needs a centre for laser research. But if Belgium had not found the money for supporting those doing the initial work on lasers, there would be no core for a centre of excellence. So, van Geen freely admits, a management policy for basic science needs care.

Policy makers must also be prepared to wind down some centres — for example nuclear fission research — the report points out, to make room for solid state, modern optics, new materials, microelectronics and biotechnology. Scientists individually must also be flexible. "I had a policy of high flexibility as a university rector — I think it's not only possible but essential." A scientist needs mobility among fields of research; and among institutions (moving among industry, schools, universities, government); and geographical mobility.

The CNPS ten-year forward look, says van Geen, shows by example that really creative developments in science occur when some overlap occurs between disciplines. It is not sufficient to put a physicist *near* a biologist, they need to work on the same problem, the report argues. But van Geen admits some problems with a directive policy on mobility, flexibility, overlap and centres of excellence. "You must decide *who decides* about the new fields. There you must be very careful. I don't like a 'Russian' system where someone — a bureaucrat — says OK you're doing physics but next week you'll do maths and then two years later biology. You must put people in the right place; and give them also the means to be flexible, the means to learn new fields."

This, then, is the van Geen/CNPS approach to science policy in Belgium; and the reader must decide for himself or herself whether it leaves enough room for basic science to breathe. □

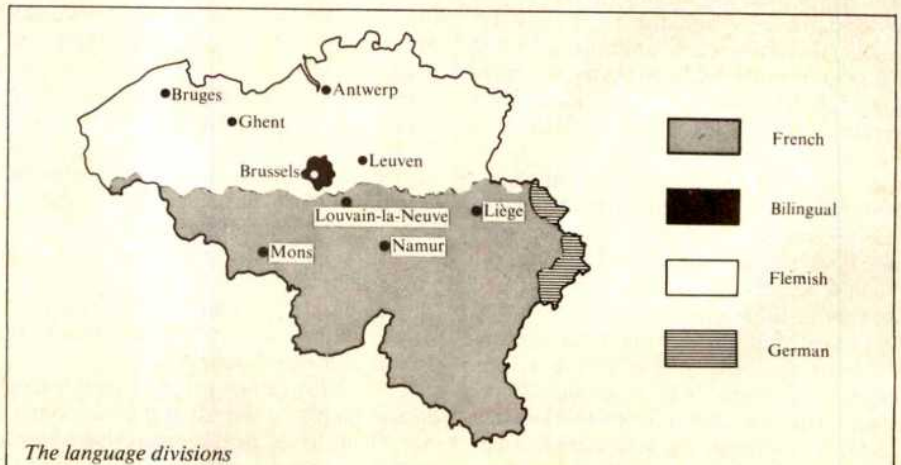
Regionalism

Increasing divide worries centre

THE latest, unpublished report from CNPS — the Belgian national advisory council for science policy — pulls no punches on the "community problem".

Some 55 per cent of the population are Flemish, and 45 per cent Walloon. They speak very different languages, which mark out the history of Europe: the Walloons, in the south, speak the Latin language, French, and the Flemish speak Dutch, which is close to German. The languages differ greatly, and speakers on each side have great trouble learning the other's language.

Moreover, regionalism is increasing. Nineteen-eighty was a turning point, when the national government devolved funds and powers, including policy on applied science, to new regional "executives" (so named to distinguish them from the local "governments" of a true federal system like those of Canada or Germany) plus a separate executive for bilingual Brussels.



Amidst this complexity CNPS has asked the national government to clarify the funding system for science. "Science policy is very difficult now in Belgium", says CNPS president Professor R. van Geen. "Some people want a Flemish and a French science policy — but scientific research is a universal thing."

For example, take the government's science policy office (SPPS, science minister Maystadt's executive arm). SPPS is still national. But on both sides of the country there are demands that it be split in two parts.

But, pleaded van Geen, "You must be careful in what you say, as I hope the new equilibrium [between national and regional forces] will help and not hinder research".

"We try to create a balance [in the unpublished CNPS report, which advises on policy for Belgium's next ten years of science] but it is very difficult." The topic is "so electrically loaded today that you have to be very careful. Please report this carefully", said van Geen "as we don't know what the equilibrium state will be". It is "not impossible" that Belgium will split into two nations ("I don't want that — I say that clearly".) In the present circumstances, "fission" could arise out of some political or economic accident.

The community problem has flared up lately for four reasons: first, population. For a long time the French dominated both numerically and politically, but now the Flemish have become numerically dominant and are demanding a redistri-

The language divisions

bution of money, industry, jobs and political power. Today the Walloons feel they are the victims, when for a century the reverse was true.

Second, Belgium is going through an economic crisis. In the past, community problems have been solved by throwing money at them, yielding equally to "the four forces": Flemish, French, Catholic, and non-Catholic (which means agnostic, rather than protestant, in Belgium). But now Belgium has to decide where to put the little money it can spare: it cannot afford equilibrium.

Third, Flanders is undergoing a rapid economic expansion, with green-field sites for new industry and a more docile population (in terms of strike record) than Wallonia, weighed down by big, troubled industries like coal and steel.

And fourth, regionalism is increasing everywhere in Europe: the Basques, Brittany, Scotland for example.

So far there has been no serious violence over the regional issue in Belgium — but it could happen. Belgians look in fear at Northern Ireland. And there is a possible flashpoint: a small community of 4,000 people in Belgium which is contested between both sides: a small bit of land which has become a symbol. To judge by some newspapers, the major political problem in Belgium today is that the mayor of this community cannot speak Flemish. There has been some violence there — guns, bombs — but so far without victims. "Violence is increasing", says van Geen, "I just hope it will not explode." □

New technology

Flanders sets the pace

FULL of bounce, the Flanders regional executive, in just its third year of operation, is leaping into high technology.

High technology is political: the president of the executive, Mr Gaston Geens, an economist by training, has grasped technology as the lever that will lift Flanders above the rest of Belgium and establish it as a state within a state. And it is all happening very swiftly, after the law of August 1980 that regionalized a measure of responsibility for economic policy and applied research. (Fundamental research and the basic funding of the universities remain national.)

The Wallonian executive has seen the challenge set by the breathless Flemish executive, and is also making strong efforts — particularly in biotechnology — but it has the harder task. Wallonia has the old industry, Flanders the new, and moreover Flanders is going through a kind of spiritual rebirth, emerging from a century and a half of French domination.

It may be, of course, that Flanders will pull the whole of Belgium with it, and the regional competition will prove highly creative; but meanwhile everyone in Flanders knows what high technology means for the region and its politics — independence — and there is almost no public or trade union opposition to the changes, even though, for example, rampant robotization of Flanders factories is creating no new jobs and eliminating some old ones.

Flanders did have some old industry, mainly in textiles, and that has suffered in the general recession like Wallonia's steel and coal. But, claim Flanders officials, the Flemish textiles industry is now automated and competitive again.

The officials also say that Flanders now accounts for 70 per cent of all Belgian exports, compared with Wallonia's 25 per cent. (The rest comes from the Brussels region.) Moreover, last year there was a 21 per cent increase in investment in Flanders, says the executive, whereas the total investment in Belgium is decreasing.

Ford, for example, is investing some BF 10,000 million (£125 million) to automate its Flanders factories. Employment levels will be unchanged, but, says the executive, if it did not invest, employment would fall with competitivity.

"The people accept this better here than in Wallonia", says Luc van Nuffel, microelectronics adviser to Geens. Recently, there was a one-day general strike in Belgium, in protest at the economic crisis. The strike was better observed in the French region than the Flemish, and — claims van Nuffel — if the unions were not national, there would have been no strike in Flanders at all.

It is against this kind of background that the Flemish executive is backing the new technologies — and it has been able to move fast by making use of the many reports of the national advisory council on science policy (CNPS). The executive has moved nowhere more rapidly than in microelectronics. In this, and other developments (the executive has three programmes, on new materials and biotechnology as well) the executive is attempting to move in harmony with the three universities of the region: the Catholic University of Leuven, the Flemish Free University of Brussels, and Ghent.

However, the executive believes in concentration of its resources (which total 7 per cent of the whole national government budget) and so it is proving a force for selection, which has suffered in Belgium because of the usual balance that had to be struck between the "four forces". In microelectronics, for example, the executive focused on Leuven, but in such a way as to draw in the other universities in an inter-university scheme.

The Flanders microelectronics education plan is almost literally exponential. Flemish electrical engineers have been, and will be trained in 14 industrial (technical) colleges and the three universities. "The problem was that only one university [Leuven] was training the people that industry needed", said van Nuffel. To transfer this knowhow the excecutive took four lecturers from outside Leuven and put them through a very intensive, specially-designed course at Leuven in very-large-scale integrated circuit (VLSI) design. The following year these four trained another thirty. In the third year (which begins this September), these thirty will go back to their institutions (universities and technical colleges) and introduce courses on VLSI.

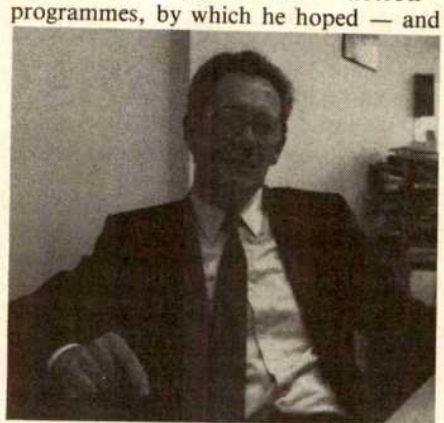
Moreover, in order to intensify the training, the executive has set up a computer network based in Leuven but linked to every teaching institution. Students in colleges throughout Flanders will use it for real-time, computer-aided chip design, using the Leuven software and equipment.

The expected result: that every year from 1986 onwards Flanders will be producing 200–300 engineers with specialist experience of custom VLSI design. VLSI research will be concentrated in a new BF 2,300 million inter-university centre at Leuven: IMEC. A company (Inventive Systems) has been established to promote chips in industry. And Flanders has given 49 per cent backing to Bell-Antwerp (an offshoot of ITT) to set up a custom-chip production plant at a total cost of BF 3,000 million. The plant is to be operational in 1985, and will have the capacity to make an estimated 4 per cent of the needs of Europe. Around 40 per cent of the production will go to ITT, 60 per cent for outside sale. The objective in backing Bell-Antwerp was to give Belgium some strategic independence in the chip market, but van Nuffel could not estimate what fraction of Belgian demand the factory might satisfy.

The executive has worked out similar programmes for materials and biotechnology, but these are still at the planning stage. In materials there is a study concerning the setting up of a laser applications centre; and in biotechnology the executive was expecting the results of a study on a communal, time-shared pilot plant in May. (The plant would be either in Brussels or Ghent.)

Eventually, the regional executives hope to get more money to play with, as certain national laboratories and funds are regionalized (often against their will). For example the national applied research council IRSIA had just been officially one-third regionalized: a third of its budget divided between Flanders and Wallonia. Flanders will get 60 per cent of that one third, and IRSIA's advice on the distribution of that fraction in Flanders will be advice to president Geens rather than to the national government. Says van Nuffel: "it makes no sense, say, if IRSIA supports traditional industry while we support new technology". Thus IRSIA and other institutions will increasingly feel the pressure of regional politics. □

Microelectronics



Silicon Valley comes to Belgium

PROFESSOR Roger J. van Overstraeten speaks with hardly a pause, and with constant intensity: it is easy to see how he has established — in less than 20 years after graduating from the University of Stanford, California — an extraordinary microelectronics laboratory in his native Belgium, a laboratory which now almost flies free on industrial contracts, depending on the government for only 20 per cent of its budget.

However, that proportion is about to change: the Flemish regional government is investing capital of BF 2,300 million (£30 million) and annual expenditure of BF 1,000 million (£12 million) to expand Overstraeten's group into an inter-Flemish-university laboratory: IMEC (the inter-university microelectronics centre). Reflecting general amazement at such expenditure in the straitened circumstances of Belgium, IMEC has earned the title: "Superlab".

The nucleus of IMEC will be van Overstraeten's group ESAT (electronics, systems, automation and technology) which he started in 1965 as part of the electrical engineering department of the (Flemish) Catholic University of Leuven. ESAT is highly renowned in its field. According to the research vice-president of the Dutch-based multinational Philips, ESAT's work on computer-aided design of chips puts it second only to Berkeley, California. ESAT has already spawned a clutch of successful small companies in the United States and Europe, and is highly sought-after for consultancy work.

ESAT started slowly, with a staff of just eight people in 1970. "That's when we really got a start. We had proved that it was possible to do some original work in microelectronics in Belgium. . .", and as a result the group won one of the first handouts from Prime Minister Théo Lefévre's "concerted action" programmes, by which he hoped — and succeeded — to improve the financial and competitive position of some of Belgium's top groups.

Van Overstraeten — boss at "Superlab"

As say many of Belgium's researchers, the concerted action cash was extremely important. At ESAT, the improvement was something like an order of magnitude. By 1975 ESAT had 60 people, when it merged with another laboratory to reach 85. Its present 150 is "saturation" for the space and facilities available — hence Superlab.

ESAT works in three areas. The most important, "integrated systems", deals with everything to do with integrated circuits, including ESAT's strong group in computer-aided design (which started early, in 1969), and a group dealing with the physics and chemistry of chip manufacture.

"We have developed 5 micron CMOS technology, 3 micron CMOS technology, and transferred it to industry. It's unique that a university laboratory should go so far [towards industry] says van Overstraeten. "But we did it partly because there was no Belgian company in the field — we did it to prove what Belgium can do". Now there are five Belgian chip companies, some of them headed by ESAT staff.

Van Overstraeten's ambition is national: why else would he have come back from Silicon Valley? And he set up in university rather than industry "because I think that education and training are extremely important — and training is still our main objective. Every year at ESAT we train 100 electronic engineers in this field. [Superlab will double or treble that number.] And all of them have the chance of designing integrated circuits."

"So I think that a laboratory like this should be between university and industry. It's not a typical university laboratory, but it's not an industry laboratory either."

Belgium will also soon have MIETEC, a joint venture between Bell-Antwerp and the Flemish executive, due to begin producing custom chips in October 1985. "I don't think a company like that could have started in Belgium without the people we have trained."

ESAT also works in systems and signal processing. More and more this field will require custom-designed integrated circuits, van Overstraeten believes. Part of the signals research is fundamental mathematical work in cryptography. For the implementation of a code is always a specific integrated circuit, "and more and more it gets difficult to separate these things . . . a mathematician alone can end up with something that would be difficult to implement in 20 years," whereas codes are needed on a 5–10 year time scale.

The third area of ESAT work is photovoltaics — based on technology similar to that of integrated circuits. ESAT developed a screen printing technology for making solar cells, 4 years ago, as an application of existing integrated circuit technology. The process is materials-efficient, and is now the property of a new Belgian company, Photon Technology, doing well according to van Overstraeten. . .

There are other laboratories like ESAT on a scientific level, van Overstraeten admits. "But if I take integration with industry, there's none like it. It's different from Stanford, and from Berkeley. There the industry is to hand, here we had none." And ESAT has international links with industry in the United States, Switzerland, Germany, Holland, France, the United

Professor van Montagu's local industry

MANY Belgian basic scientists are now turning to applied science — but some with more success than others. One of the more successful ones is Professor Marc van Montagu, plant geneticist at Ghent. Van Montagu has contracts with many companies, but has also set up his own — just started last year: Plant Genetic Systems (PGS). (Van Montagu's Ghent colleague, Professor Walter Fiers, also runs a company — an offshoot from Biogen, a genetic engineering company: Bioghent.)

Such enterprise is not unknown among molecular biologists — but van Montagu's PGS does stand out for one unusual policy: "We mostly hired people locally — in Belgium. We've seen other groups take people from all over the world, but they just end up with a collection of competent but competitive people, without a common spirit. So we wanted to take a different approach, to get the spirit going first, to show we can do it, and then give the team additional help by injecting foreign people if it needs them."

PGS will "apply our techniques to engineer plants to improve their commercial value, for example for resistance to viral and fungal disease, to increase nutritive value. Those are the things we think we can do now . . . and also a lot of work on soil microorganisms. And we have started in association with the university of Brussels (ULB) a programme on protein engineering."

The students don't object to working with industry, says a "pleased but surprised" van Montagu. "Most of the younger students find it challenging to do applied research . . . I used to think that they would object for political, ecological, or other reasons." They don't.

His group has a patent on some Ti plasmid vectors "but we decided the money should go to the university. We don't know if it's making money yet. It takes a long time."

PGS was started with BF 400 million (£5 million) and must live from the interest on that capital plus contact research. The goal for the end of 1984: to be in balance on the current account. □

Kingdom — "that's quite unique too" claims ESAT's director.

But ESAT still needs government support: "Our funding now is quite strange, we are living mainly on projects — only 20 per cent comes from the university and fixed funding — that makes life very dangerous" — particularly when electron beam apparatus can cost $3 million.

ESAT has been supported by three concerted action programmes, by national programmes, by the EEC, IRSIA, the science policy programming service, FNRS, and several ministries. The university pays 25 salaries. "But most important is that the university allows us this openness, and that they support us in getting funds." Van Overstraeten says he is not bothered by the lack of university posts. He can make do on soft money. And the people who work in his laboratory are sure of a job in industry.

And now comes Superlab, IMEC: it will be an important laboratory, with 150 permanent staff and 100 people working on projects in design and technology. (ESAT's present budget is about a third of IMEC's projected spend.) IMEC, available to the universities of Leuven, Brussels (Flemish side) and Ghent, and technical colleges, will also have closed-circuit television, so the courses and seminars at IMEC can be followed at the other centres, with audio feedback for questions. "It's a new formula for a research laboratory, an inter-university centre combined with interaction with industry".

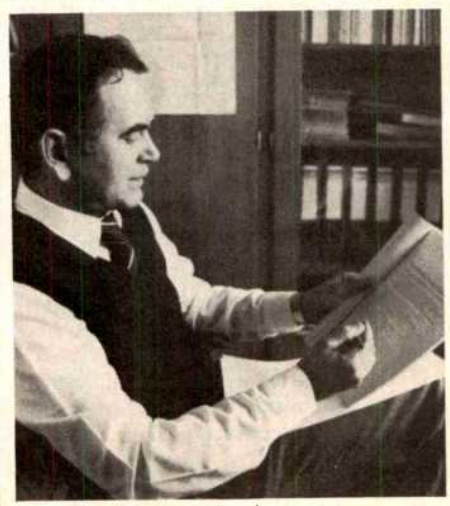
IMEC could not have been founded without government investment. The investment in people is so huge, a university could not do it. But the *national* government could not have begun IMEC — because it required a choice between regions and a focusing of funds.

. . . Belgium may sound complicated. . . but finally things seem to work out quite well. . .

IMEC is thus "a Flemish thing, but the research will be European — and we'll work for French-speaking companies, there's no problem there". Nevertheless, says van Overstraeten, "If I look at Maystadt [the national science minister] he's doing excellent things. . . Belgium may sound complicated and it is, but finally it seems to me things work out quite well. . . ".

Flanders is developing fast, the mentality is different, the industry is different, it is a challenge for the French side, but, says van Overstraeten, "I don't think they'll stay behind". □

Luxembourg



Old industries in decline

RESEARCH in Luxembourg? It does exists. Luxembourg boasts a long-dead Nobel Prize winner and in 1977 the Grand-Duchy began to expand its tiny research capacity. But Luxembourg's government science is on a very small scale — just 12 researchers in the basic sciences, who really are only nominally independent: as they recognize themselves, they depend absolutely on collaboration with groups abroad. Perhaps only 0.1 per cent of the Luxembourg gross national product is spent on both basic and applied research (but there are no official figures).

The Grand-Duchy has only the population of a large London borough — 366,000 people — and no full university, although it has 3,000 in university education, mostly abroad. But it had the coal and iron ore to justify a major steel industry (Arbed), which ten years ago employed half the working population (now the fraction is plummeting to a quarter). Arbed has a research laboratory with 30–40 staff. Luxembourg also hosts the Goodyear tyre company's European research laboratory (with some 150 researchers). And some smaller companies also do research in Luxembourg, mostly on metals and materials.

But Luxembourg really could do more research, and needs to in order to be prepared for the new industries that must follow steel. And, indeed, in 1977 a Mr Robert Krieps, minister for cultural and scientific affairs in the — rare in Luxembourg — socialist coalition government, began a slight movement in that direction. Krieps created a number of new institutions for research, among them an advisory council for research policy headed by chemist Professor Pierre Seck. One of the biggest new creations, says Seck, was a small-scale teaching hospital where some important research is done. And Krieps created institutes for technology (technical colleges) that do some applied research.

But despite 3,000 potential students, Luxembourg does not have a complete university. What it does have is the beginnings of one: the Centre Universitaire (CU) with 800 students, created ten years ago, which offers just the first year of university studies. (This is where Luxembourg does its basic research.) The CU first year is intensive, with an amazing student-teacher ratio of 2 to 1, and CU courses are widely recognized by other universities in Austria, West Germany, Belgium and France.

Pierre Seck — not quite alone.

If CU staff, like Seck and his five colleagues in the department of science, want to do research "we have to collaborate with a team abroad". CU research interests can be listed in total: a collaboration with a French CNRS director working on ecty-steroids in insects at the University of Strasbourg has revealed the same ectysteroids in worms; chemistry at the CU has focused on heterocyclic and organometallic compounds, in collaboration with the universities of Metz, Heidelberg and Louvain; the CU physicist works with Centre Hospitalier on medical electronic signals, seeking correlations with disease. And there is one pure mathematician, in a world of his own as far as Seck is concerned. . .

The CU department of science has around 40 teachers, but only Seck and his five colleagues are employed by the CU alone: 20 of the others are upper-level teachers at *lycée*, qualified to teach both at secondary and tertiary level. Then 6 come from foreign universities on secondment, and 10 are professionals such as doctors and engineers.

Research in the CU is done by the 6 full-timers. "But we've recently won a new freedom — to release some of the secondary school teachers for several days a week." That gives a total of about 12 man-years per year of research capacity at the CU, except for the teaching load.

It is small team, but, says Seck, his laboratories "are very well-equipped for the subjects we've chosen" with apparatus like a Mossbauer spectrometer, NMR and X-ray diffractometers, and the department is promised a new building.

Thus basic research in Luxembourg proves viable, at least while it remains linked to the science going on in surrounding countries, and while it is not so ambitious as to outstrip the country's capacity.

The only trouble is that Luxembourg science is like an unfinished painting, a few dabs of industry, public and private research that could do with a little coordination. "We have to grow together." Aware of this, in 1983 the members of the research advisory council demanded more power to coordinate and fund Luxembourg's science. The council would not continue without that power, the members threatened.

But the government — since 1979 led by the Christian Socialist (right wing) party that has ruled Luxembourg almost continuously since the nineteenth century — called the bluff and simply failed to renew the council's mandate. At the time of writing the council's future is unclear, but Seck has hopes for new developments after the June national elections. □

Fourier's law obeyed — official

Analysis of a mechanical model characterized by deterministic randomness (chaos) allows verification of elementary principles of heat conduction. But it may have other value.

THOSE who hold that the reductionist programme is a mistaken attempt to account for all phenomena in terms of elementary processes usually look for evidence to support their case in the behaviour of living things. They may be well advised, it seems, to pay closer attention to a long-familiar part of classical physics and in particular to the theory of heat conduction.

The problem, as a little reflection will show, is that there is still no unambiguously unobjectionable way of calculating from the laws of dynamics as applied to atoms and molecules the most elementary principle underlying the phenomenon of heat conduction — the notion that the rate of heat conduction between two parallel plane surfaces in some medium is proportional to the temperature difference between them, widely known as Fourier's law. From this simple statement follow the differential equations which specify the time-dependent variation of temperature or of heat flux in conducting objects of all kinds. Calculations based on Fourier's law have naturally been widely used in tasks as different as the inference of temperature distribution within the Earth and the design of industrial heat exchangers. So in what sense can Fourier's law be less than well grounded in physical principles?

The familiarity of Fourier's law no doubt blinds us to its non-trivial character. It is not, however, difficult to construct other plausible phenomenological schemes to describe the rate of heat conduction through material objects. The most obvious modification is that suggested by the process of radiative heat transfer: each element in a body at a temperature different from absolute zero might give rise to an isotropic heat flux which is simply a function of the temperature of the element. For small temperature differences, Fourier's law would be approximately true, and while the rate of heat conduction through a fluid from some solid object would awkwardly be a function of the temperature of that object, it might in practice be hard to distinguish such a variation of conduction away from a source of heat from the variation with temperature of the heat conductivity of media of all kinds.

But surely, even schoolboys will ask, has not this issue long since been dealt with? Heat conduction through gases is familiarly dealt with by kinetic theory, with results entirely in accordance with Fourier's law. For more general fluids, it may be necessary to take account of more complicated treatments of transport in kinetic systems along the lines originally proposed by Enskogg, but the objectives are the same — to calculate the rate of transport of kinetic energy from the distribution of the momenta of particles and the chance of collisions between them. In metals, on the other hand, it is more prudent to start from the likely excitation of conduction electrons into states of higher energy, and to allow for the interruption of free electronic motion in such a state by the vibration of the underlying lattice. Although most of this is intricate, in principle it is straightforward. So why should Peierls (in 1961) have written that the derivation of Fourier's law from elementary dynamics is "one of the outstanding unsolved problems of modern physics"?

Peierls' remark derives from his own work in the 1950s on the interaction between lattice electrons and the spacings of the underlying lattice. That the interaction may sometimes mean that a regular lattice breaks up into consecutive insulating patches or, alternatively, will permit the efficient transport of electrons in the forms of "solitons" is now part of the familiar understanding of conduction in solids, superconductivity in particular. The deficiencies of the theoretical foundation of Fourier's law consist, from this point of view, in the way in which all attempts to calculate heat transport (and other transport processes) from first principles rely, at some level, on an averaging process.

This is the starting point for a calculation published by Joseph Ford and Franco Vivaldia (Georgia Institute of Technology), Giulio Casati (Milan) and William M. Visscher (Los Alamos) at the end of last month (*Phys. Rev. Lett.* **52**, 1861; 1984). Their first task is the choice of a deterministically random (or chaotic) mechanical system with which to model a solid heat conductor. Such a system must be simple enough to be calculable, at least numerically, yet free from exceptional modes of behaviour that might vitiate the modelling of thermal conductivity and yet sufficiently complicated to be vaguely reminiscent of the real world. With fashionable but needless whimsy, the authors settle for what they call a "ding-a-ling" system — a one-dimensional array of hard spheres similarly anchored by symmetrical restoring forces to fixed lattice points with equal freely moving spheres sandwiched between them. At the end of the array are two thermal reservoirs, which communicate with the conducting array by means of similar freely moving spheres, which if accepted into the reservoir are promptly returned with a velocity specified by the velocity-distribution appropriate to the corresponding temperature.

The model works straightforwardly. The stiffness of the lattice-bound particles has to be great enough for chaotic motion to supervene. What happens is that the oscillating spheres act as relatively unresponsive transducers for energy carried by the intermediate freely moving spheres. The rate of energy transport can be estimated from the rate at which energy emerges from the high temperature end of the system, or from the equal rate at which it arrives at the other. The numerical calculations have been carried through fully only with very short linear chains, with two and four anchored spheres respectively. The result, cheerfully, is a constant coefficient of thermal conductivity (within ten per cent or so). The argument has, however, been made more plausible by means of a calculation of next-nearest neighbour correlations (between neighbouring anchored spheres) for a more general system, from which again a constant thermal conductivity is derived.

So far, then, so good. Here is a simple dynamical system with many of the recognizable characteristics of a heat-conducting solid which does indeed transduce energy in accordance with Fourier's law. Many people will no doubt now be tempted to embark on generalizations of this simple model. Two dimensions? Even three dimensions? Excessive zeal of that kind would be misplaced. What Casati *et al.* have done is to demonstrate that a dynamical system does indeed behave as would be expected under the influence of a random input of impulse. In passing, they have also been able to show that in strictly mechanical systems such as these, the exceptional dynamical solutions, the putative solitons, are no great encumbrance if the vibrational frequency of the anchored spheres is sufficiently great. The other side of this coin is that such models might indeed be used for studying energy transport in, say, superconducting materials. Whether reductionists should be alarmed by all this is quite a different matter, although some of them may be dismayed that this may be that hitherto elusive problem for which only computer solutions are attainable.

John Maddox

Palaeontology

Biased record of early life

from Malcolm Walter

IF an expedition to Earth from some other planet were to be mounted, and if the budget restrictions were such that only two samples could be collected to determine the history of life on Earth, it is probable that the palaeontological advisors to the expedition would urge the collection of a black chert to represent the first few billion years of biological history. Suppose, then, that the collectors travelled first to an island in Hudson Bay, where they gathered a sample of the 1.8×10^9 year old black chert[1], and then to Shark Bay in Australia or some similar arid shore[2], where they gathered a sample of extant life from the intertidal zone. When the two samples were analysed on return from Earth, it would be concluded that there had been no evolutionary progress for at least 1.8×10^9 years, and that the Earth was still in 'the age of cyanobacteria'.

Palaeontologists are aware of biases resulting from selective preservation. Disproportionate attention to cherts is not a result of naiveite on the part of the palaeontologists who work on Proterozoic sequences, but is a consequence of the very success of the studies concentrated on cherts[3]. Ever since the seminal discoveries in the 2×10^9 year old gunflint chert of Ontario[4], black cherts have been known as a good preservative for microbial cells, and consequently many studies, including that of Zhang Yun[5] on page 547 of this issue, have focused on them. As a result, our view of the Proterozoic history of life is probably grossly distorted. Zhang Yun adds to the small but steadily growing list of described microfossil assemblages which represent much of our information about life in Early Proterozoic times (1.65–2.50×10^9 years ago). Although there are techniques, such as the study of stromatolites and isotope geochemistry, that give us different sources of information about ancient life[1], microfossils are preserved cells and the most direct evidence we have. Of the various sources of information available to palaeontologists, microfossils have received by far the most attention. They are preserved in very finely crystalline silica, chert, and as a result of circumstances not yet well understood, most Proterozoic microfossiliferous cherts appear to have formed in the marine intertidal environment.

The attention to a limited set of palaeoenvironments has consequences in biostratigraphy as well as palaeobiology. Any attempt to use chert microfossils in biostratigraphy is greatly limited even before it begins, unless we can find cherts that preserve samples of microbial life from more than just the intertidal zone. Like a few other assemblages, Zhang Yun's could represent a microbiota that was unique to the Early Proterozoic. The first reaction to this new report is to view it as an encouragement to biostratigraphers, but caution is needed. As in the case of most of the other examples, including the original one from the famous Gunflint Iron Formation, the Chinese example comes from rocks whose depositional environment has not been determined by modern sedimentological techniques. The fact that its microbiota are distinctive may therefore signify nothing more than that it comes from a distinctive palaeo-environment (Zhang Yun suggests the shallow sea in a region of volcanic activity) that has, so far, only been sampled in the Lower Proterozoic — a familiar problem to palaeontologists.

Proterozoic microfossils are also found in shales, where they are called acritarchs, but there they are studied by different techniques and usually by different scientists from those who work on cherts[6,7]. Many of the shales were deposited in offshore marine environments and, as a result, contain a sampling of the marine plankton of the time. They can be expected to have been more diverse than the intertidal microbiota, not having been limited by the environmental extremes that characterize the intertidal zone. Shales should therefore provide a fuller record of evolution through the Proterozoic, and the material should provide the basis for a successful Proterozoic biostratigraphy. A combination of the palaeobiological approach that has been applied to cherts and the empirical biostratigraphical approach of the acritarch workers will give us a true picture of life in the Proterozoic, and provide the basis for sound biostratigraphy. Such work has begun[8]. □

Oncogenetics

Progress in malignancy

from Miranda Robertson

TWO rare tumours of childhood are proving to be a remarkable source of insight into the genetic steps by which cells may progress in malignancy. The tumours, retinoblastoma and neuroblastoma, have two significant features in common. First, they are both derived from embryonic precursors of nerve cells, which normally lose the ability to divide once they have differentiated; and second, both may be associated with chromosomal deletions. These two facts have been incorporated in the following hypothetical schema. The chromosomal deletion contains a gene that is normally responsible for turning off the embryonic phenotype, including the ability to divide; in its absence, embryonic genes remain active and the proliferative capacity of the cell is retained. It has been suggested that some of the cellular proto-oncogenes may be genes that are normally active only during embryogenesis; and with this in mind, Lee *et al.* have looked for an active oncogene in cells from ten fresh retinoblastomas. They find that the N-*myc* gene is transcriptionally active in all of them and amplified in two[1]. At the same time, Schwab *et al.*, who originally discovered the N-*myc* gene[2], report that in retinoblastomas N-*myc* amplification is associated with late stages of tumour progression[3], and thus may have prognostic implications.

N-*myc* is an oncogene by an unusually complex chain of inference. It was first detected by Schwab *et al.* in the amplified DNA of a number of neuroblastoma cell lines through its limited homology to the c-*myc* cellular proto-oncogene. Thus its identification as an oncogene rests on its relationship to a known oncogene and its presence in DNA that is amplified in tumour cells. Its activation in a second neurectodermal tumour — retinoblastoma — strengthens the evidence implicating it in neural tumorigenesis.

The first step in the development of neuroblastoma and retinoblastoma must occur before the differentiation of the central nervous system is complete, and indeed may be inherited. The hereditary cases are often associated with chromosomal abnormalities involving the deletion of material from chromosome 1 in the case of neuroblastoma[4], and from chromosome 13 in the case of retinoblastoma[5]. This is believed to predispose individuals to develop the tumours, but does not make it inevitable, presumably because a normal allele of the deleted gene remains on the intact chromosome. In the case of retinoblastoma, there is now very good evidence that the second step in tumorigenesis is the inactivation of the normal allele[6]. (The mechanisms by which this may occur in retinoblastoma and other childhood

tumours have been the subject of two recent articles in *News and Views*[7,8].) Whether the inactivation of both alleles is sufficient for malignancy is not known; but there is some evidence for activation of a member of the c-*ras* oncogene family in a neuroblastoma cell line[9], suggesting that it may not be.

What is the significance of the transcriptional activation and amplification of N-*myc* in retinoblastoma and neuroblastoma cells? Nothing is known about the function of the N-*myc* product, but c-*myc*, with which it has some homology in the 5′ coding region, is implicated in the control of proliferation in several different cell types[10], and it is possible that N-*myc*, whose expression seems to be confined to cells of neurectodermal origin[11], has an analogous role in neural cells. In neuroblastoma moreover, the level of transcriptional activity seems to be correlated with the degree of differentiation of the tumour cells[11], which can vary considerably within a single tumour. Schwab *et al.* have shown by hybridization *in situ* that N-*myc* expression is higher in the less differentiated cells.

The association of N-*myc* amplification with tumour progression is suggested by investigations by Brodeur *et al.* on a series of 63 tumours taken from untreated patients at four different stages of the disease, defined chiefly by the extent of dissemination of the tumour cells. Brodeur *et al.* find no amplification of N-*myc* in 15 tumours at stages 1 and 2; but amplification in half of the 48 tumours from stage 3 or 4 patients[3]. The prognosis for patients at these later stages is usually extremely poor, two-year survival being 10–30 per cent, compared with 75–90 per cent for earlier stages. If the correlation with N-*myc* amplification holds up, it will be important to discover whether the absence or presence of the amplified gene distinguishes late-stage patients who may survive from those who will not. Such a prognostic tool could help with difficult decisions on the more heroic forms of therapy in advanced disease.

More fundamentally, further research on the interactions of the several genes now implicated in the genesis of neuroblastoma should help to illuminate the mechanism of neural differentiation and its disruption in tumorigenesis. □

Particle physics

How neutral are atoms?

from Frank Close

UNIONIZED atoms are electrically neutral because the negative charges on the electrons precisely balance the positive charges on the nuclear protons. This concept of balancing is so deep-rooted in our scientific culture and so naturally presented in school classes that we hardly give it a second thought. In fact it is really rather profound; why should electrons and protons, which seem to be independent forms of matter, know so precisely the magnitude of each other's electrical charge?

An answer that has suggested itself to many is that ultimately there is but one type of matter: electrons and protons are siblings. If so, this would be the culmination of a long search for an underlying unity in nature. At the beginning of the century scores of atomic elements were thought to be the templates of nature's infinite variety. Then it was realized that three 'elementary particles' — electron, proton and neutron — were the common building blocks of all atoms. Later the proton and neutron were discovered to be built from more basic particles, called quarks. Now we believe that quarks and leptons are the two fundamental families of matter. Yet the precise identity of their electrical charges hints that they might not be totally unrelated, and in the grand unified theories (GUTs) uniting the electromagnetic, weak and strong forces, one finds that quarks and leptons are siblings. This startling result is a consequence of the electrical charge equality between the electron and proton. But how sure are we that these charges are identical, and what consequences would ensue if they were different?

Einstein had suggested that the electron and proton charges (Q_e, Q_p) might not be precisely equated and that:

$$Q = (Q_e + Q_p)/Q_p \sim m_p/m_{pl} \sim 10^{-19}$$

where m_p and m_{pl} are the proton mass of 1 GeV and the Planck mass of 10^{19} GeV respectively. Twenty-five years ago Bondi and Lyttleton noted that if $Q \sim 10^{18}$, electromagnetic repulsion would dominate gravitational attractions among hydrogen atoms on a galactic scale and the expansion of the Universe could thus be explained within Newtonian mechanics (*Proc. R. Soc.* **A252**, 313). Since that time the hot big bang model has been established so we may now take this as a possible cosmological bound on $Q < 10^{-18}$ for hydrogen.

The first precision test on the electrical neutrality of atoms was performed by A. Picard and E. Kessler 60 years ago (*Archs Sci. phys. nat.* **7**, 340). In their experiment, all ions were removed from a vessel containing a gas. As the gas leaked out of the vessel, they measured the change in the vessel's electrostatic field. If $Q \equiv 0$ there should be no change. Their limit for Q was $< 2.2 \times 10^{-19}$ for carbon dioxide. Other experimenters have used this technique on nitrogen and argon and have typically obtained limits $< 5 \times 10^{-20}$, consistent with the standard folklore value of 'zero' but perhaps not a definitive falsification of Einstein's hypothesis. Indeed J.G. King applied the Picard–Kessler technique to hydrogen and helium and obtained a small negative charge for hydrogen of $(-2.5 \pm 1.5) \times 10^{-20}$ and a small positive charge for helium of $(4 \pm 2) \times 10^{-20}$ (*Phys. Rev. Lett.* **5**, 562; 1960). Subsequently, King has claimed, but not to my knowledge published, details of a null result for H_2 and for He where $Q < 6 \times 10^{-21}$.

What about elementary particles that are believed to be uncharged? A nonzero charge for the neutron can be sought by passing neutrons through an electrostatic field. The most precise limit appears to be due to R. Gahler *et al.* (*Phys. Rev.* **D25**, 2887; 1982): $Q(n) = (-1.5 \pm 2.2) \times 10^{-20}$. For the neutrino, the value comes from astrophysical arguments. If neutrinos are electrically charged, then photons can convert to neutrino–antineutrino pairs and affect the rate of stellar evolution. We know that our Sun has survived for over 5×10^9 years and this places an upper limit on the rate of energy loss by a possible neutrino pair production. J. Bernstein *et al.* find that this limits the neutrino charge: $Q(\nu) < 10^{-13}$ (*Phys. Rev.* **B2**, 1227; 1963).

If, as generally believed, electromagnetic interactions are described by a local and causal field theory, then electric charge must be conserved. Thus in the β-decay of the neutron into proton, electron and neutrino, $Q_e + Q_p = Q_n + Q_\nu$. So if one accepts charge conservation, it provides a better limit on Q_ν than the astrophysical argument. But there is nothing that requires each side of this relation to equal zero.

The question of the electrical charges of fundamental particles has recently been investigated by Okun *et al.* of the Institute of Theoretical and Experimental Physics, Moscow (*Phys. Lett.* **138B**, 115; 1984). In electrodynamics, and in the electroweak theory of Glashow, Salam and Weinberg, the electric charges are not fixed: proton and electron could have arbitrary charges. The reason for this lies in the mathematical group structure of the theories. Electrodynamics is based on the gauge group $U(1)$, and the electroweak theory on $SU(2) \times U(1)$. The $U(1)$ factor gives a freedom to the charges of the matter particles which form the representations of the group. The β-decay equality must be preserved, but the magnitude of $Q_e + Q_p$ is arbitrary. However, in GUTs based on compact semi-simple groups, such as $SU(5)$, the electrical

charges are determined. If the electrical charge operator is a generator of a semi-simple group, then the sum of the electrical charges of the particles in a multiplet of the group vanishes. In the simplest GUT based on $SU(5)$, the fundamental quarks and leptons form two distinct multiplets and hence two separate combinations of charges vanish. Together with the β-decay constraint, this places sufficient constraints to determine the charges of all the quarks and leptons. The electron and proton charges are identical and of opposite sign; the neutron and neutrino charges are both zero.

Leptons and quarks belong to the same multiplet and so group transformations can convert quarks into leptons. As a result, protons, made from quarks, can decay. Searches for proton decay are in progress; the candidate events and lifetime do not appear to be in accord with the simplest $SU(5)$ GUT. GUTs based on other gauge groups are still viable. The gauge group $SO(10)$ is among the best investigated. Here the quarks and leptons fit into a single multiplet and hence only a single set of charges vanishes: the charges are less constrained than in $SU(5)$. Combined with the β-decay constraint one finds an amusing consequence. The hydrogen atom is neutral; the charges of neutron and neutrino are opposite but not necessarily zero. So hydrogen is neutral, but heavy atoms are not if $Q_n \neq 0$.

Do grand unified models require equality of electron and proton charges? Conversely, would a difference in their charges, albeit small, rule out the grand unification programme? Okun *et al.* show that, in principle, grand unification is possible in such an eventuality. However the price is that there must exist a number of Higgs particles (these are predicted to be responsible for generating masses of W, Z particles and the fundamental matter field) so vast that their presence in virtual states would destroy standard low-energy electrodynamics. It is possible to avoid this catastrophe, but even so the models do not look very attractive.

Within the grand unified philosophy, then, it seems we must have $Q_e + Q_p \equiv 0$. The present limits, of the order of 10^{-20}, are tantalizing and it is by no means ruled out that an improvement could bring unexpected results. Indeed, experiments searching for evidence of fractional charge on niobium balls are using balls containing of the order of 10^{20} electrons and protons. If there is an imbalance in $Q_e + Q_p \sim 10^{-20}$ it would lead to a net charge on the ball that could mimic a fractional charge. This would not show up in experiments with oil or smaller metal drops, where as few as 10^{12} protons and electrons are sometimes present. It is possible that null results in these experiments could place strong limits on the electron–proton charge equality. □

Cardiac physiology

A finger on the pulse

from A.F. Brading

In the determination of the mechanisms used by the heart to control its intracellular ions and regulate the rate and strength of its beat, the emphasis is shifting from descriptive accounts of factors affecting intracellular calcium to a more mechanistic approach in which the behaviour and control of the various processes involved is under scrutiny. So much was clear from a recent symposium* on the regulation of contraction in cardiac muscle.

The resting level of intracellular calcium is controlled by a combination of intracellular buffering and transmembrane pumps and leaks. Experiments on intact muscle and on isolated sarcolemmal vesicles reported at the meeting brought out the possibility that comparatively simple systems may underly the considerable complexities seen in intact preparations. From measurements with ion-sensitive microelectrodes of the intracellular activities of sodium and calcium and of membrane potential in sheep Purkinje fibres and ventricular trabeculea, in a variety of conditions, the stoichiometry required of a Na–Ca exchange for it to determine the intracellular free calcium has been calculated (H. Fozzard, University of Chicago). Fozzard finds that intracellular calcium adjusts so that the relationship between the sodium and calcium electrochemical gradients is unchanged, and fitted by a coupling ratio of 2.5 with a 'reversal potential' near the resting potential. J.P. Reeves (Roche, Nutley) has characterized an equivalent system in isolated vesicles of cardiac plasmalemma. It consists of a symmetrical exchange of one Ca^{2+} for three Na^+ in a direction determined by the calcium and sodium gradients and the membrane potential. He maintains that in normal resting conditions in the intact heart, the exchange will not be at equilibrium, and will mediate net calcium efflux even during membrane depolarizations to about 0 mV. These results suggest that other processes are more important than Na–Ca exchange in setting the level of intracellular free calcium, although the electrogenic exchange may contribute to the membrane potential under appropriate circumstances.

The rise in free calcium during the contractile cycle involves its entry through the membrane and release from the sarcoplasmic reticulum (SR). Calcium channels and transmembrane calcium currents can now be elegantly monitored with the patch-clamp technique, and R.W. Tsien (Yale University) illustrated the behaviour of voltage-sensitive calcium channels in normal conditions and in the presence of calcium antagonists and agonists. He suggested that the calcium channel operates in one of three modes, within each of which the channel may exist in one open and two closed configurations, with rate constants dependent on the membrane potential and the mode. Calcium antagonists bind preferentially to a mode in which channel opening is a rare event whilst the calcium agonists stabilize a mode in which the channel open-time is prolonged and the closed-time shortened. The mode existing most frequently in depolarized conditions is characterized by relatively short but fairly frequent channel openings. The interesting possibility was raised that there might be endogenous ligands which could modulate channel behaviour.

Calcium release from the SR is acknowleged to be one of the most important factors responsible for elevating free calcium levels. A. Fabiato (Virginia Medical College) has investigated its importance in mechanically skinned single cells with an exceedingly sophisticated set-up in which changes in the solution around the cell are made in a microprocessor-controlled and precisely timed sequence. The solutions contain aequorin, and its light signal and changes in tension are used to monitor calcium release. It seems that calcium entry during the spike triggers calcium-induced calcium release from the store, and depolarization of the SR membrane plays little part in the release process. Fabiato believes that the calcium is released via a calcium channel which is both activated and inactivated by free calcium on the outer surface of the SR. This means that release is not merely triggered by the level of free calcium but depends also on the rate of change of calcium activity. Inactivation starts at a lower concentration of free calcium than does activation, and with a much lower rate constant. Rapid application of supramaximal calcium levels will inactivate the process before release is triggered, but in the continuous presence of supraoptimal calcium concentrations another process of oscillatory calcium release is triggered (also described by D. Eisner, University College, London, in intact tissues with elevated intracellular calcium) which may trigger arrythmias in intact heart.

Once intracellular calcium is raised, its ability to activate the contractile machinery can also be modulated. For example, by correlating tension and intracellular calcium activity (measured using aequorin), J. Blinks (Mayo Clinic) showed that, following activation of catecholamine β-receptors, calcium becomes less effective at producing contraction,

*A Physiological Society Symposium on 'Myocardial intracellular regulation: consequences for the heart', University College, London, 28–29 March 1984.

whereas following α-receptor activation, the contractile apparatus becomes more sensitive to calcium. Activation of either receptor results in positive inotropy, but that produced by β-receptor activation is due to cyclic-AMP-dependent increases in calcium entry and calcium release from the SR.

The final meeting session covered clinical aspects. The underlying effects of hypoxia on mammalian hearts and the mechanisms of action of cardiac glycosides and the anti-arrhythmic agent lidocaine were discussed with reference to the involvement of the mechanisms discussed in earlier sessions. The possibility of developing more useful positive inotropic drugs was discussed by P. Poole-Wilson (Cardiothoracic Institute, London), but the meeting appeared to be somewhat pessimistic about this being achieved in the near future. □

DNA replication

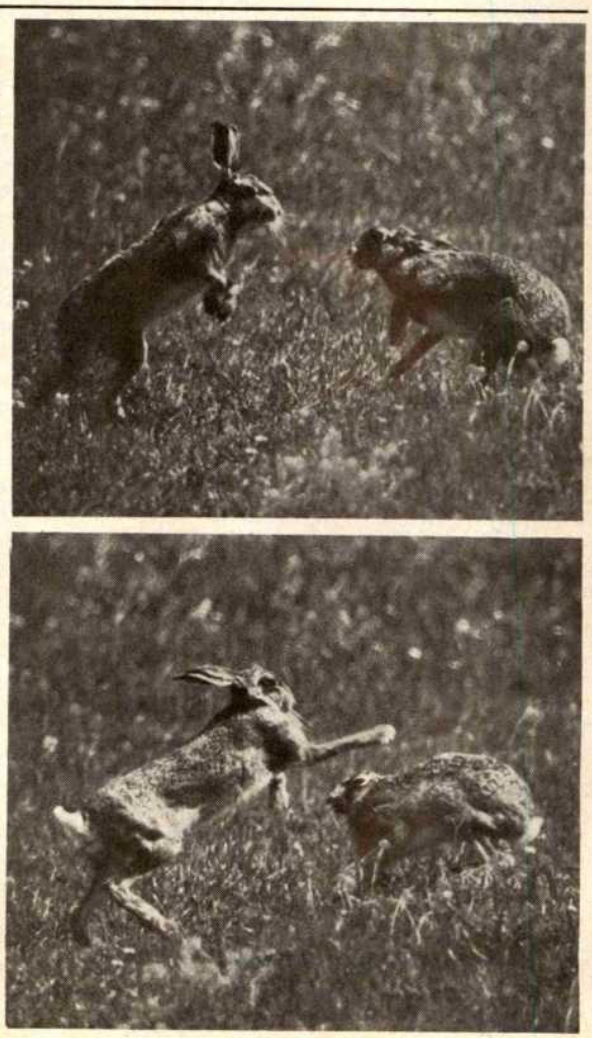
A twofold amplifed view

from David T. Denhardt

How does the mammalian cell accomplish orderly replication of its genomic DNA? Among several hypotheses, perhaps the most popular is the analogy with viral systems — that is, specific sequences in the DNA are activated in a regulated fashion by 'origin-activating' proteins, which cause replication to begin at what would then be considered replicon origins. Recently, a window onto this process has been opened as the result of studies on the replication of amplified, or amplifiable, replicons. In a well designed series of experiments, Mariani and Schimke have demonstrated the amplification of the gene for the enzyme dihydrofolate reductase (*DHFR*) in Chinese hamster ovary (CHO) cells in the course of a single cell cycle (*J. biol. Chem.* **259**, 1901; 1984).

During the normal cell cycle, the *DHFR* gene is replicated once in early S phase. When Mariani and Schimke blocked the entrance of a synchronized population of cells into S phase with hydroxyurea — an inhibitor of ribonucleotide reductase and so of DNA synthesis — replication of the *DHFR* gene was severely inhibited. Upon release from the block, the gene was rapidly replicated. More interestingly, and contrary to expectation, when replication was inhibited by hydroxyurea shortly after the cells had entered S phase, at a time when the *DHFR* gene had been replicated, within 12 hours the gene was replicated again.

The evidence is convincing that, within a single cell cycle, twofold amplification of the *DHFR* gene occurs in a substantial portion of the cell population. What this result suggests is that when DNA replication is inhibited by hydroxyurea partway through S phase, the cells revert back to their pre-S state. Hence, after removal of the block, the cells initiate replication of their DNA all over again. In effect, at least when the inhibition occurs in early S phase, the cell cycle clock is turned back to the boundary between the G_1 and S phases.



If an explanation for these events is to be sought in terms of 'origin-activating' proteins, one might infer that their stability is enhanced when DNA replication is inhibited to an extent sufficient to permit them to initiate a second round of replication within the same cell cycle. Programmed stability of an 'orgin-activating' protein would readily account for the amplification of the chorion genes of *Drosophila* follicle cells seen in the elegant electron micrographs obtained by Osheim and Miller (*Cell* **33**, 543; 1983).

Reinitiation at previously used origins during the same S phase has also been detected by, for example, Lavi, who demonstrated that when simian virus 40-transformed CHO cells are exposed to DNA-damaging agents (alkylating agents, aflatoxin) both the integrated viral genome and certain unlinked genes (*DHFR*, the *HLA* locus, c-Ha-*ras*) are amplified (*UCLA Symp. molec. cell. Biol.* **11**, 659; 1983). Moreover Barsoum and Varshavsky have shown that mouse 3T6 cells, which amplify their *DHFR* genes in response to the presence of the DHFR inhibitor, methotrexate, will do so with greater facility in the presence of tumour promoters and mitogenic hormones (*Proc. natn. Acad. Sci. U.S.A.* **80**, 530; 1983).

Support for the idea that there are specific origins of replication in mammalian DNA was reported last year by Hamlin and co-workers (*Nature* **302**, 439; 1983). They studied the replication in synchronized cells of the *DHFR* region in a CHO line carrying a 1,000-fold amplified *DHFR* gene (plus adjoining DNA) and found that replication of each of the 1,000 copies of the amplified DNA started in the same restricted region of the DNA and proceeded away from that origin in a bidirectional manner. Although the origins of replication have not yet been localized to a defined nucleotide sequence, this will surely soon be accomplished. □

CAMELIA VS CADET

On her travels in Wonderland, Alice was given the choice of heading in the direction of a Hatter or a March Hare. She chose the latter because "The March Hare will be much the more interesting, and perhaps, as this is May, it won't be raving mad — at least not so much as it was in March". Lewis Carrol, and Martin Gardner after him in *The Annotated Alice*, were wrong to ascribe such a specific seasonal insanity to the Brown Hare, according to 1,500 hours of observations by Anthony Holley and Paul Greenwood summarized on page 549 of this issue. The mad behaviour of hares is continuous throughout their long breeding season which lasts from January to August, and is no more frequent in March than in any other month of that season. Equally wrong, they conclude, is the traditional belief that the pairs of hares seen madly boxing are both males, and that the boxing represents intrasexual competition. On the contrary, boxing is between a female and an unwanted suitor: here Camelia is seen to be getting the better of Cadet.

Biopolymers

Silken spider chains

from Paul Calvert

SILK is best known as the fibre spun by the larvae of many moths to form a protective cocoon for pupation; most commercial silk is from the domesticated larvae of the moth *Bombyx mori* with some 'wild' silk from the Tussah silkmoths *Antheraea*. A great variety of other insects also make silks, fibres of which find uses as supports, shelters and attachments, but the real silk specialists are spiders. Despite the efforts, in the eighteenth century, of M.Bon of Montpellier, who made himself stockings and gloves from spider silk, it has caught on neither commercially nor scientifically. Research papers on spider silk, such as that by Gosline *et al.* on page 551 of this issue, are therefore rare treasures.

Most silks are proteins, containing a predominance of glycine, alanine and serine. For instance, *B. mori* silk is close to a simple repeating (Gly-Ala-Gly-Ala-Gly-Ser) structure. By comparison, spider dragline silk stands out in having 10 per cent each of proline and glutamic acid. In properties and structure, the silks are first cousins to the nylon fibres. Commercial nylons, however, do not have such a high density of amide units as the silks because it makes for strong hydrogen bonding, which results in a melting point too high for processing and a fibre that is too water-sensitive. A shirt that becomes elastic when wet could be a little discomforting; but for animal silk, hydrophilicity is essential as it permits the fibre to be spun from aqueous solution.

The paper of Gosline *et al.* builds on the work of Work and colleagues who showed there to be a 50 per cent contraction, along with a twofold volume increase, when spider dragline fibres are allowed to swell in water (*Textile Res. J.* **47**, 650; 1977 and **52**, 349; 1982). (The Work papers are worth reading at least for the description of how to milk a spider of its dragline.) This water sensitivity is particularly strange in that the dragline must support the falling spider and yet the twinned lines of the garden spider, *Araneus diadematus*, which can weigh 0.65 g, break at 1 g (see F. Lucas *Discovery* **25**, 20; 1964; Lucas & Rudall *Compreh. Biochem.* **26B**, 475; 1968). Such a close strength specification seems to leave little room for rapid deceleration and none for unpredictable properties.

Gosline *et al.* show that the uptake of water converts the amorphous regions of the fibre to a rubbery state. Silks, like synthetic fibres, are composites of small crystalline regions and rigid glassy amorphous regions. For spider silks, no information on the proportions of the two phases seems to have been published, but most natural and textile fibres are at least 50 per cent crystalline. On swelling in water the glassy regions become plasticized so that the chains are mobile, and possibly some of the crystals melt. The result is that the structure relaxes, the chains in the amorphous regions coil up and the modulus decreases by a factor of 1,000. If the fibre is stretched and dried, the original properties return. This process is similar to heat shrinkage of synthetic fibres; for instance, drawn polyester fibres, when heated to 240°C, shrink by 75 per cent and the modulus drops 50-fold (M.P.W. Wilson *Polymer* **15**, 277; 1974).

The size of the modulus drop in spider silk is surprising. The final modulus of 10^7 Pascals is more like that of true rubber than that of a partly crystalline polymer — the modulus of a 50 per cent crystalline polyethylene is 50 times higher. This suggests that the water-resistant crystallinity of spider silk is very low and that most of the dry fibre is oriented glassy material. A reasonable guess would be that the high proline and glutamic acid contents are responsible for preventing much crystallinity developing. This appears strange when the spider could have produced a strong water-resistant fibre of the silkmoth or nylon type. What the spider gains is a fibre that is about twice as strong as *Bombyx* silk and has a very much larger extension (30 per cent) before it breaks. This extension will gradually slow the falling spider rather than there being a thread-breaking jerk. The penalty, apparently, is a rather disconcerting change in behavior in the rain.

Synthetic fibre makers should be impressed by the range of properties attainable within the silk group and spurred in their efforts to control polymerizations to the point where silk-like structures can be duplicated. As a general rule it is very hard to increase the strength of a material without also decreasing the extension to break; the way that both are improved at once in spider silk, compared with silkmoth silk, is impressive. □

Cell physiology

Cellular site of calcium regulation

from Andrew P. Somlyo

THE concentration of free (ionized) calcium (Ca^{2+}) regulates not only muscle contraction, but also a variety of other cellular processes including glycogen metabolism, secretion, membrane transport and permeability. In muscle, an intracellular organelle system, the sarcoplasmic reticulum (SR), can store and release calcium, and so regulate cytoplasmic Ca^{2+} in the absence of a change in total cell calcium. But what plays the part of the SR in non-muscle cells? The suggestion that it is the mitochondria seems to have stemmed, in part, from the great attention given to mitochondrial Ca^{2+} transport[1,2]. When exposed to high (unphysiological) concentrations of Ca^{2+}, mitochondria can accumulate very large amounts of calcium phosphate salts, nearly enough to be turned to stone. As known since the time of Lot's wife, this is an eye-catching device, but not conducive to much further activity. Here I shall summarize some of the compelling arguments why opinion is shifting strongly away from mitochondria towards the endoplasmic reticulum (ER) as the regulator of cell calcium.

Subcellular fractions containing ER and showing Ca^{2+}-accumulating activity have now been isolated from a wide variety of tissues[3-10]. In some instances, contamination by ER vesicles may account for active calcium uptake attributed to some other organelle, such as synaptic vesicles[11] and, perhaps, vertebrate retinal discs. The ER calcium pump resembles the SR system in using ATP (although other high-energy phosphates can substitute) as an energy source, in being enhanced by calcium-precipitating anions such as oxalate and phosphate and in being inhibited by SH-reactive organic mercurials[10]. Moreover, a phosphorylated 118,000-molecular weight protein, thought to be analogous to the phosphorylated intermediate of the SR Ca-ATPase, has been identified in ER from rat liver[12]. The affinity of several isolated ER preparations for Ca^{2+} is sufficiently high ($K_m \sim 0.2$–$0.6\mu M$) to reduce cytoplasmic Ca^{2+} to the low levels typical of normal resting cells. It has yet to be determined whether there are specialized regions of the ER with a high capacity for storing calcium, like the terminal cisternae of striated muscle SR. The identity of the subfractions of ER largely responsible for calcium-accumulating activity is not known, although it is probably not inherent to the rough endoplasmic reticulum[6].

The introduction of new techniques has greatly advanced the identification of the ER as the source and sink of intracellular calcium in non-muscle cells. For example, whereas squid axons are sufficiently large to permit the manipulation of their intracellular Ca^{2+} by internal perfusion[13,14], for smaller cells, membrane permeabilization by agents, such as saponin, has been used to manipulate intracellular Ca^{2+}. This has allowed investigators to identify the ER as

a calcium storage site, by showing that Ca^{2+} accumulation occurs even at low Ca^{2+} concentrations at which mitochondria cannot accumulate calcium or when mitochondrial calcium uptake is inhibited[10,15]. Thus ER in liver cells, synaptosomes and macrophages has been shown to accumulate Ca^{2+} at the low concentrations required of a physiological regulator. A more direct approach has been to visualize, through electron microscopy, sometimes combined with electron-probe X-ray microanalysis, the deposits of calcium (or strontium, which acts as a more electron-opaque substitute for calcium) oxalate in the ER of synaptosomes[5], squid axons[13], photoreceptor cells[16] and endothelium[17].

For the ER to regulate cell Ca^{2+}, it must have not only a mechanism of calcium uptake, but also one of calcium release. On stimulation of cells by hormones or transmitters, the signal for Ca^{2+} release may be mediated by a change in the properties of the surface membrane, most commonly depolarization, and/or by a diffusible intracellular second messenger. The feasibility of the first mechanism is suggested by the close (about 10–20 nm) proximity of ER subsurface cisterns to the plasma membrane. These structures, which resemble the 'surface couplings' of cardiac, smooth and some skeletal muscles, have been observed in some non-muscle cells[18-20] and may be present in all eukaryotic cells. There is also evidence that electrical stimulation of the surface membrane of fibroblasts, known to contain subsurface cisternae, can release calcium from an intracellular source, probably the subplasmalemmal ER[20]. The second possibility, that an endogenous intracellular messenger releases calcium from the ER, has recently received strong support. Thus in pancreatic cells[21], in isolated hepatocytes[22] and in insulinoma cells[23], a phosphatidylinositol metabolite, inositol trisphosphate, has been shown to release intracellular Ca^{2+} from a non-mitochondrial site, presumably the ER. It was further observed that caffeine releases intracellular Ca^{2+} from a non-mitochondrial source in rat nerve cells[24], reminiscent of the caffeine-induced Ca^{2+} release from the SR of skeletal muscle[25]. Caffeine-induced Ca^{2+} release from the ER has also been observed in macrophages[8], but not in liver[15].

The first inkling that mitochondria might not have a significant role in the regulation of cytoplasmic Ca^{2+} followed the observation that, in the presence of physiological Mg^{2+} concentrations, the affinity of isolated mitochondria for Ca^{2+} is too low[26]. In the normal cell, Ca^{2+} fluctuates, at most, from 5×10^{-8} to 5×10^{-6} M between rest and maximal activation, while the Ca^{2+} concentration required for a half-maximal rate of calcium transport by mitochondria is 10^{-5} M or higher[17,26]. Furthermore, in intact cells, the calcium content of mitochondria is relatively low compared with that of the SR and even after sustained increases of Ca^{2+} within the physiological range in maximally contracted muscle, mitochondrial calcium content is not increased[17]. On the other hand there is no question that in the presence of inorganic phosphate (P_i), mitochondria can accumulate massive amounts of calcium and, perhaps, become initial sites of pathological calcification when cell Ca^{2+} (and P_i) rises to abnormally high levels due to cell damage. In injured cells, mitochondria may serve as the final low-affinity/high-capacity buffer for Ca^{2+}, and moderate loading of mitochondria by Ca^{2+} may be an alternative to cell death. It remains to be shown that such cells survive and that mitochondria can discharge their excess Ca^{2+} to the extracellular space via the various surface-membrane-mediated calcium transport mechanisms that must ultimately maintain the steady-state calcium content of cells. One candidate for a naturally occurring 'transmitter' that can release mitochondrial calcium has been identified: sodium can discharge calcium from mitochondria isolated from heart, brain and skeletal muscle, although not from liver, kidney and smooth muscle mitochondria[2].

What, then, is the physiological role, if any, of the complicated mitochondrial calcium transport system so passionately pursued by biochemists for nearly 20 years? One possibility is that, although mitochondria do not have the capacity to regulate cytoplasmic Ca^{2+}, they themselves can respond to changes in cytoplasmic Ca^{2+} concentrations by producing very small changes in the Ca^{2+} of the mitochondrial matrix space[27]. A number of the mitochondrial enzymes (dehydrogenases) are sensitive to Ca^{2+} in the range 0.1–10 μM. Therefore, small changes in mitochondrial Ca^{2+}, achievable by even a relatively inefficient (low-affinity) calcium transport system, could have important effects on oxidative metabolism.

While far from complete, the case (even in plants) for the ER as the major intracellular regulator of Ca^{2+} has clearly become much stronger during the last few years. The lumen of the ER communicates with the perinuclear space where, in some instances, high concentrations of calcium (or strontium) have been demonstrated. Perhaps an ER system, capable of accumulating calcium against a gradient in the nuclear membrane, was acquired with the nucleus when cells became eukaryotes. Unfortunately for biologists, living systems often evolve to use different structures and mechanisms to solve the same problems (photoreceptor systems and contractile regulation are but two examples), and grand unifying schemes with fundamental principles applicable to 'all cells' are rare. In the regulation of cell Ca^{2+} by the ER in all nucleated cells, we may have a rare example. □

100 years ago

ARRANGEMENTS have been made by the Council of the Scottish Meteorological Society for the completion this season of the Observatory of Ben Nevis. The first portion of the Observatory was, it may be remembered, opened in October last, and since the observers went into residence continuous hourly observations have been made of the conditions of the atmosphere at the top of the Ben, with special reference to temperature, pressure, humidity, and motion. From the discussion of these, and what were daily made by Mr Clement L. Wragge in the summers of 1881 and 1882, by the Secretary, Mr Buchan, the Council have been fully confirmed in the high expectations they had formed concerning the value of a high-level station, both in its bearing upon general meteorological problems, and also with reference to possible forecasts for the British Islands. The additions to be made to the Observatory will just double its size, and enable the three observers — who during the winter have been considerably cramped in their one apartment — to work under more comfortable conditions. On the south of the present doorway there is to be erected a shelter for tourists. The estimated cost of the completion of the Observatory will be 800l., which is, however, irrespective of a heavy item of charge for conveying on horseback the materials to the top of the hill. It is understood that the cost of equipment and maintenance of the Observatory heretofore has been heavier than was anticipated. The directors intend shortly to make a fresh appeal for funds to the public, which will no doubt be as liberally responded to as was their last.

From *Nature* **30**, 179, 19 June 1884.

Mutations and oncogenes — cause or effect

SIR — In a field as complex as carcinogenesis, it is difficult to distinguish between cause, correlation and consequence. No thoughtful biologist needs to be reminded of the many cancer theories propounded in this century. The current version is represented by the flood of papers on oncogenes and karyotypic abnormalities as the underlying cause of cancer, with amplification in the popular press.

The problem in unqualified acceptance of the claims can be illustrated by an examination of some details of specific and nonspecific chromosome changes in cancer. The most thoroughly investigated of the specific or nonrandom changes is the Philadelphia chromosome (Ph^1) associated with over 90% of human cases of chronic myelogenous leukaemia (CML)[1-3]. However, there are patients with typical CML whose leukaemic marrow cells are Ph^1 negative at first, but become Ph^1 positive later[4]. In one case, Ph^1 negative and Ph^1 positive cells were observed in the same clone of leukaemic cells[5]. The evidence suggests that blood cells remain karyotypically normal but unstable for some time after the initial malignant transformation but provide a milieu favourable for the establishment of the Ph^1 anomaly[5].

Similar evolution of nonrandom chromosome alteration occurs in sarcomas induced in rats by infection with the Schmidt–Ruppin strain of Rous sarcoma virus. More than 80% of the tumours have a normal diploid stemline[6]. In some cases, all the cells are normal diploid while in others there are a few near-diploid sidelines or pseudodiploids. In older tumours, however, heteroploidy is common and usually involves the specific, sequential addition of three particular chromosomes. Without a careful impression that the chromosonal aberrations are a prerequisite for tumour formation since the predominance of normal diploid cells in early tumours is sometimes not noted when the nonrandom changes are discussed[7].

Many of the reports of nonrandom chromosome changes or activated oncogenes in tumours are based on studies of cultured lines of the tumour cells. The caution that must be used in interpreting them is illustrated by a study of eight human gliomas[8], each of which had a unique and broad distribution of karyotypes ranging from hypodiploid to as much as hypertetraploid when first placed in culture. Reference sets of frequent karyotypes were established for each of the tumours, only 7 to 25% of the clonal karyotypes were represented in the reference sets. Thus in no case were the cells which were maintained in culture representative of the original tumour, and any conclusions drawn from their analysis could not be applied to the bulk of the tumour cells. All of the examples given demonstrate that progression within the tumour and selection in culture obscure the relationship between cause and effect.

Chromosome studies have an advantage over molecular analysis of oncogene analysis because karyotypes can be obtained of individual cells, and a population distribution determined, whereas the biological and chemical methods used to identify oncogenes represent an average of the whole of the population. Furthermore, karyotype analysis is technically simple and has been pursued even in clinical laboratories for many years, so it has provided a depth of information, particularly in human cancer, not yet available in oncogene studies.

There are, however, hints that the questions raised about the role of chromosome changes in tumour development have their parallels in studies of oncogenes. Most of the positive reports of oncogene activation derive from transfection studies with DNA from cell lines[9]. (Chemical identification of activated oncogenes in some 50 reported cases of human cancer has been negative[9]). The most prominent cellular oncogenes are related to acute viral transforming genes which are known to give a selective advantage for cell growth in culture. The possibility must therefore be considered that cell structure selects for a minority mutant cell in the original tumour population. The activated oncogene would then be no more representative of the tumour cells than was the clonal karyotype in the glioma representative of the tumour karyotype.

It has recently been shown that a human osteosarcoma cell line which was negative on transfection to NIH3T3 cells could become positive after treatment with *N*-methyl N'-nitro-*N*-nitrosoguanidine (MNNG), a mutagen and carcinogen[10]. The chemically-transformed cells were more transformed in appearance than the original cancer cells and produced more tumours in nude mice. Obviously the "oncogene activation" was an epiphenomenon unrelated to the original tumour. Although this activation may have played a role in the secondary transformation of the tumour cells in culture by MNNG, even this is uncertain, since a similar enhancement of the transformed phenotype in the same cancer cells by another carcinogen was not accompanied by detectable onocogene activation. Many more inconsistencies in the ever burgeoning oncogene literature could be cited to raise suspicion about their purported role in carcinogenesis (see ref. 9). At the most, their role in tumorigenesis appears to be auxiliary[11], at the least inconsequential.

As confirmed recently in *Nature*, the initial effects of carcinogenic treatment affect the entire population of exposed cells[12] and therefore cannot be genetic. The rarer, random occurences which characterize the secondary stages of transformation[12] can be explained as well by differentiative[13] as by mutational events. Indeed, the great mass of (largely dormant) evidence which indicates that cancer is the far end of a spectrum of development of cell and tissues[14,15] seems to be only selectively disinterred to rationalize gaps in mutational theories of cancer. The lack of an adequate mechanistic explanation for developmental processes and their derangement is no justification for ignoring them.

Oligodendroglia in multiple sclerosis

SIR — The report by Ludwin[1] that the oligodendrocyte proliferates around an injury to mouse brain is of great relevance to previous studies on the neuroglia in mutliple sclerosis (MS). Some twenty years ago, we demonstrated proliferation (or at least increased numbers) of oligodendroglia at the edge of active MS plaques[2,3]. This observation has recently been confirmed by electron microscopy[4].

Although oligodendroglia are essentially absent from the centre of MS plaques[2,3,5], their proliferation at the edge of the lesion suggests either a response to injury or their involvement in repair of the damaged myelin. Ludwin's dynamic isotope study clarifies the controversial issue of the oligodendrocyte's potential to undergo hyperplasia and possible role in repair.

Archaeomagnetic dating of Santorini volcanic eruptions and fired destruction levels of late Minoan civilization

W. S. Downey* & D. H. Tarling

Department of Geophysics and Planetary Physics, University of Newcastle upon Tyne, Newcastle upon Tyne NE1 7RU, UK

Archaeomagnetic dating on the Minoan ash horizons of the Santorini volcano and on fired destruction levels at late Minoan sites on Crete demonstrates that the basal (Plinian) air-fall ash of the first 'Minoan' pumice is contemporaneous with the destruction levels on central Crete, while the higher 'Minoan' ashes are contemporaneous with the destruction levels in extreme eastern Crete. These destruction levels were almost certainly caused by seismic activity, rather than the ash fall. The determination of a time gap between these events lead to a reappraisal of the archaeological evidence and is important volcanologically.

THE excavation of a highly advanced Bronze Age culture in Crete and surrounding islands at the turn of this century, led to speculation[1] that this Minoan civilization was the basis of some Homeric legends and also of Atlantis. Further excavations apparently indicated that the widespread devastation and extensive burning of towns, palaces and isolated villas were synchronous[2], and that this appeared to be simultaneous with the eruption of the Santorini (Thera) volcano, 120 km north of Crete (Fig. 1). Marinatos[3] proposed that there was a direct relationship between the two events and others, such as Luce[4], have shown how such an association is consistent with features of the Atlantis legend. It has also been shown[5] how the volcanic activity could account for the Egyptian plagues and events that occurred as Moses was leading the Israelites out of Exile.

The distribution of ash in the Eastern Mediterranean and seasonal wind patterns suggest a summer eruption[5,6] and Biblical references[7] also indicate late spring or early summer. The ashfall could thus have directly destroyed growing crops. The ash clouds may have contained fluorine[8]. It has also been suggested[9,10] that tsunamis destroyed the Minoan fleet, leaving the area open to invasion. However, objections have been raised to such suggestions particularly as they depend on the eruption of Santorini being synchronous with the destruction levels. Unfortunately no dating method is sufficiently accurate to determine the date of either event. Dating by ^{14}C has given a wide variety of ages[11–15]—the most widely accepted are between 1700 and 1200 BC, mainly because such a range is broadly consistent with the archaeological evidence[16]. This is based on wall paintings in Egypt, contemporaneous with Thotmose III, which depict envoys from Crete attributable to late Minoan IB (LMIB) times. LMIB vases in Egyptian tombs of this age indicate that Cretan LMIB time corresponds with Thotmose's reigh, 1503–1447 BC[17].

Acidity layers in the Greenland ice sheet, attributed to pollution of the atmosphere by the Santorini eruption, have a calculated age of 1390 BC[18], while frost damage in tree rings of the bristlecone pine in southern California have been dated as 1626 BC[19]. If *Exodus*[20] does record the Santorini volcanic events, this was 480 yr before Solomon's fourth year: 1446 BC, although other dates have been suggested, such as 1250 BC (J. V. Luce, personal communication). There is thus no consensus of any one date for the volcanic eruption.

Archaeomagnetism[21,22] has conventionally been used as an 'absolute' dating method, based on the fact that fired materials are capable of retaining a magnetic remanence so that the direction and intensity of the geomagnetic field can be determined for the time that the materials were cooling. For periods when the directional and intensity changes are known, such fired objects can be dated by comparing their properties with that of the previous geomagnetic field. Advances have been made in establishing such geomagnetic secular variation records in many parts of the world, with results from Bulgaria[23], in particular, extending the knowledge of the geomagnetic field in southeastern Europe over the probable age of the Minoan eruptions and destructions. However, such records are still sparse, their ages largely based on ^{14}C determinations which means that no absolute time scale for secular variation during the Minoan period has been established. However, relative dates can be determined. Materials magnetized at the same time in the same region will normally have identical directions and the intensity of the geomagnetic field would also be the same. It was on this basis that the archaeomagnetic study of the Santorini volcanics was initiated[24] and extended to late Minoan sites on Crete[25] (see Table 1).

Collection and analysis

To establish synchroneity, sufficient samples had to be collected, to allow averaging out of random errors, and had to be measured with great care. The ashes were particularly difficult to sample as most are either unconsolidated or only loosely consolidated. Collection was by the disk method[22], in which 2.5-cm plastic disks are glued to the sample, oriented and removed, with the sample attached, for measurement in a version of the Digico magnetometer[26]. The flat, upper surface of the disk was oriented with an inclinometer and, wherever possible, a Sun compass. Unfortunately some archaeological sites were protected by a roof so that magnetic compass orientation was necessary on some occasions. The individual orientations are considered to be accurate to about 1°, comparable with the instrumental measurement error, so that each sample error is thought to be of the order of 1–2°. The identification of individual components within any one sample is less precise but such errors should be random and are thus reduced by averaging. The ancient intensity of the geomagnetic field in which the geological and archaeological materials originally cooled was determined by a modified Kono and Ueno[27] method.

The magnetic minerals were identified using isothermal magnetic properties, X-ray diffraction, Curie temperature analysis, microprobe, thermal and alternating magnetic field studies. It was found that almost pure magnetite was the dominant remanence carrier in both archaeological and geological

* Present address: Dipartimento di Scienze della Terra, University of Naples, Italy.

Table 1 Details of Cretan late Minoan sites

Site	Area	Description and location of sampled areas	Usable samples
Malia	Palace (13) House ($\Delta\alpha$)	Area to the east of L'entree sud; samples burnt mud-brick from walls of low elevation. Room 7, purification chamber; inner part of NNE–SSW wall. Area 5—'block-wall' running parallel to wall of room 7 (hard 'vitrified' sandstone). Wall to east of rooms 10 and 11. Room 8, small partition mud-brick wall (magnetic compass).	20 24
Knossos	Stratigraphical museum extension site kiln 2	Upper kiln walls and kiln chamber end of channels: circular sampling distribution (magnetic compass).	26
Sklavokambos	Villa	Room 18 to west of small central court (possibly storeroom or kitchen). Interior of east wall dividing rooms 18 and 15. Room 10—burnt mud-brick and limestone samples.	16
Phaestos	Palace	3 areas: (1) area 101 beyond NE area of Palace (burnt mud-brick partitions). (2) Area to north of central court (open paved corridor[41]) vertical burnt plaster walls on east sides of corridor 41. (3) North wall of room 70 to NW of central event (possibly a lustral basin or guard room).	17
Hagia Triada	Palace	Areas near room 8 and 12—east facing wall at bottom of staircase (scala 60), burnt floor at base of staircase to west of room 8, west interior wall of room 8 at top of scale 60, north exterior wall of room 12.	17
Gournia	Town House Ac	Room 16—large floor level mud-brick wall—samples from top to bottom exterior and interior of wall were exposed.	30
Makrygialos	Villa	Samples of burnt mud-brick from low elevation walls (all orientations) and pillar bases. Also floor samples.	38
Palaikastro	Town (Block N)	Burnt sandstone and mud-brick from low elevation walls (block N). Burnt floor from compartment 9.	59
Kato Zakros	Palace	NE annexe of palace, room N; NE–SW wall, pantry LI; staircase of the shrine; inner N wall of pantry, stores L; inner E (NE–SW) wall, pantry store L; inner E (NE–SW) wall; pantry stores LI. Outer S (SE–NW) wall, pantry store L; N wall, room XI E of door; N wall, room XI, W of door; NE–SW wall, room XII (inner) to W of steps: NW–SE wall, room XI, E of door; NW–SE wall, room XV, W side; NW–SE wall room XV, SE corner; N edge of wall extending NE from room XXVI; NE–SW wall, room XXVI (W edge), NW–SE wall, room XXV (treasury); NE–SW wall, room XXV (above archive niches); doorway of N wall between rooms XXVII and XXVI. (All burnt mud-brick.)	49

samples, occurring within rapidly chilled minerals within a glassy matrix in the tephra. Subordinate titanomagnetite (X = 0.4; Curie temperature 420 °C) occurs as early phenocrysts in the tephra. The magnetic behaviour[28] indicated that the remanence was carried by either single domain or pseudo-single domains. The archaeological materials, mostly burnt mud bricks from large *in situ* structures, had been heated to temperatures above the Curie point of their magnetite. However, even unconsolidated charcoal ashes taken from floors (Hagia Triada palace and Palaikastro block N) were found to contain a stable remanence with identical directions to those of the associated burnt mud brick walls.

Results from Santorini

Any interpretation of the magnetic data from the volcanic deposits requires an understanding of how their magnetization was acquired. If they were emplaced at a temperature below that of their Curie temperature, then at least two primary components would be present—one acquired before and one after emplacement. Higher reliance can be placed on directions from a single-component system and palaeointensity determinations from a multicomponent system will be particularly difficult to evaluate. Samples of Minoan tephra were taken from locations on Santorini, ranging from close to the vent (Thera quarry) to those overlying the Minoan city of Akrotiri, 7 km from the former vent (Fig. 2). Analysis of the components, similar to that described by Hoblitt and Kellogg[29], yielded emplacement temperatures of 300 °C for both the Plinian ashfall and the base surge deposits at Akrotiri, and significantly higher values, ~500 °C for both layers, nearer to the vent. The tephra deposits overlying the base surge at Thera quarry were emplaced at lower temperatures, 300–400 °C, showing that these originated as ash flows and not mud flows[30]. The overlying ignimbrites, sampled at several sites on the eastern coast of Santorini, yielded higher temperatures, above 500 °C. (These emplacement temperature results will be discussed in detail elsewhere[31].)

The presence of two primary components of remanence in many of the ashes overlying the base surge and below the ignimbrites meant that careful analyses were required to separate the two components, and it was frequently the value of the component being removed during partial demagnetization that provided a more accurate definition of the lower temperature component than the component remaining. The ignimbrites and base surge deposits in the quarry were characterized by a single primary component and could be analysed more simply, although these were also subjected to both alternating magnetic field and thermal demagnetization, determination of linearity, planarity, and so on[32]. These analyses generally demonstrated extremely high stability using any of the standard measures, such as the stability index[33], although 25% of the volcanic samples had to be rejected where the different components could not be adequately separated. Most difficulty was encountered in the ashes immediately overlying the base surge deposits but excellent results were obtained from the Plinian ashfall, the base surge and the overlying ignimbrites. The geological and geochemical evidence indicates that the base surge, overlying choatic tephra and ignimbrites are essentially part of the same eruptive sequence[34] and therefore the less well-defined results from the chaotic ashes make little difference to the final conclusions.

After removal of viscous, short-term components by partial demagnetization, the directions of the component acquired at, and just below, the emplacement temperature were combined for the different volcanic units. This showed that the Plinian ashes were characterized by distinctly steeper inclinations than observed in the overlying ashes and ignimbrites, but all overlying tephra showed mutually consistent directions (Table 2, Fig. 2). The observed difference clearly indicates an age gap between the Plinian and base surge deposits, although this had not been

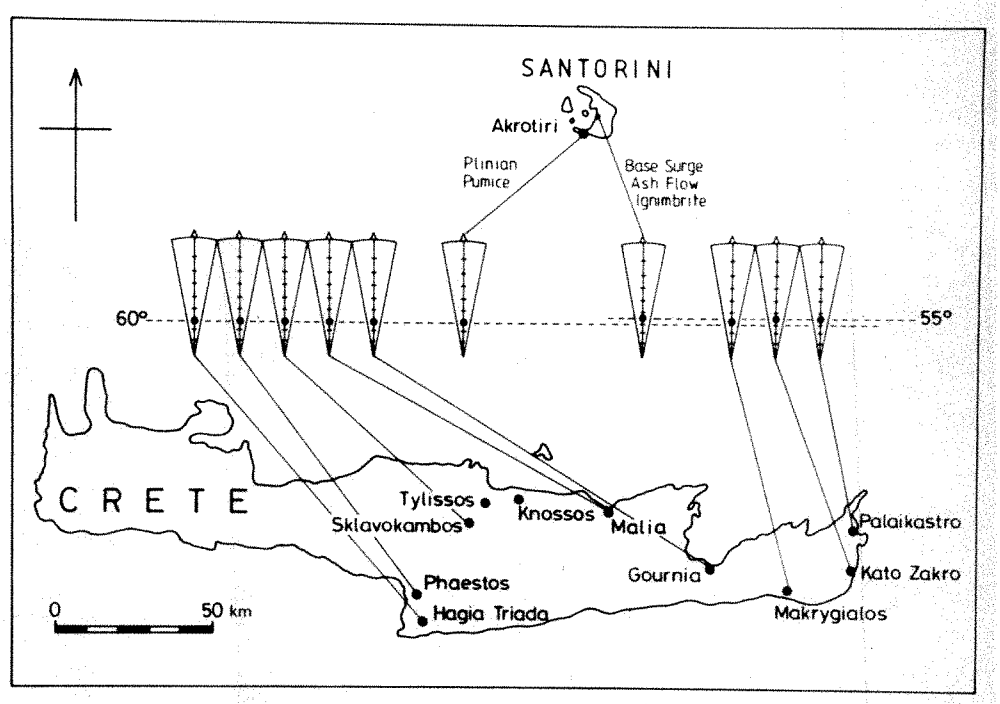

Fig. 1 Map of the sites and mean directions on Crete and Santorini. The mean directions are illustrated by means of a segment of an equal-area stereographic projection. In this projection the central line indicates north and the inclination varies from zero on the circumference to vertical at the centre. The mean direction is shown as a dot, the size of which is already greater than the 95% precision parameters associated with it. The declinations are more westerly for the projections on the left, but are not very different from those of the other projections. However, the inclinations are statistically steeper on the left than those on the right and this difference is supported by the available palaeointensity determinations (Table 2).

expected from previous geological and geochemical studies[34]. These showed little or no difference between the composition, refractive indices, and so on, of the Plinian ashes and the bottom of the base surge. Geochemical changes from within the base surge deposits into the overlying ashes were not considered significant as the base surge and overlying chaotic tephra were clearly part of the same volcanic sequence of events. Closer examination of these data indicates that the similarities between the Plinian ashes and the base surge are restricted to the very basal layers of the surge deposits and could be explained if some Plinian ashes were incorporated in the surge as it scoured across their surface. We suggest that geochemical differences may exist, consistent with the magnetic evidence for a significant time gap between the Plinian ashfall and the base surge events. (These new magnetic results differ from those originally obtained from the Plinian ash and base surge deposits[24], but previous sampling methods had restricted the collection to volcanic bombs which are now known not to be characteristic of the main tephra deposits.)

The only archaeological site which could be studied on Santorini was a small hearth structure at Akrotiri (Arvaniti 1 α 1). Unfortunately the roof over the site prevented the use of a Sun compass and the large pithoi nearby may have affected the magnetic orientations. This could account for the higher scatter ($\alpha = 3.6°$) than observed at most other archaeological sites examined in this study. The mean direction differed from those of all of the overlying ashes (Table 2), although this difference was not statistically established at a 95% probability level. However, the palaeointensity determinations on both the hearth and some pottery sherds also indicated an age difference.

Table 2 Directions and palaeointensities of geomagnetic fields recorded on Santorini and Crete

	Mean directions				Palaeointensity (10^{-4} T)		
Site	Decl. (deg)	Incl. (deg)	α_{95}	No.	Intensity	s.d.	No.
Palaikastro (block N)	355.1	55.1	1.8	59	0.530	0.030	9
Kato Zakro (palace)	355.8	54.6	1.9	49	0.607	0.024	6

Cretan results

Ten Minoan excavations were visited on Crete (Fig. 1), and their final destruction levels were sampled. To detect any deviations caused by anisotropy or magnetic refraction, samples were taken from walls in different orientations and, in the case of kilns, systematically around the wall linings (see Table 1). No evidence was found for either magnetic refraction or anisotropy. The age of each site was ascertained by consultation with local archaeologists and from literature. In all the cases, the fired levels were considered to represent the 'final' Minoan destruction levels. (At Knossos, habitation continued long after the cessation of the Minoan civilization.) These levels have largely been dated on the basis of associated pottery using, for example, Popham's classification[35] and are generally regarded as LMIB, corresponding to the presence of a 'marine' style of pottery, and therefore younger than late Minoan I A (LMIA) with a characteristic 'floral' style, although this style persisted into LMIB times. There is controversy about the stylistic classification of some isolated pots and the absence of LMIB pottery does not mean that none will be found or that the extant pottery style at one location was not contemporaneous with LMIB styles as defined at Knossos. At Malia palace, for example, few pots of confirmed LMIB have been found (O. Pelon, personal communication) while LMIB pottery is abundant at Palaikastro.

The presence of single primary magnetic components of very high stability, carried by single or pseudo-single domain magnetite, allowed very precise definition of the directions at each locality. The directions at the sites in eastern Crete (Palaikastro and Kato Zakros) were found to be identical, with the mean

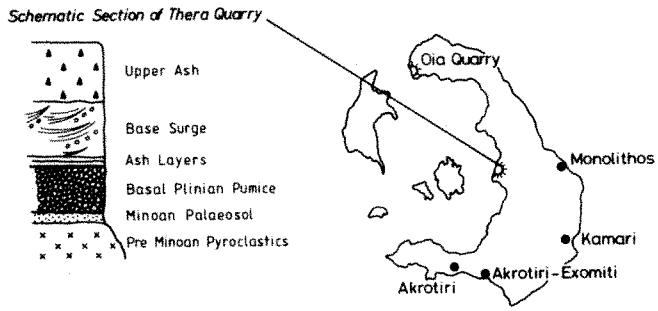

Fig. 2 Sampling sites in Santorini. Most of the tephra sampled were from the sequence exposed in the Thera quarry.

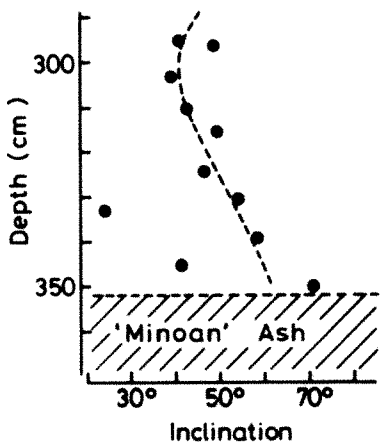

Fig. 3 Changes in the geomagnetic field as recorded in eastern Mediterranean sediments. New magnetic studies[25] of the VEMA V10-50[5] core of the eastern Mediterranean sediments show a decrease in inclination with time in the carbonates overlying the Minoan tephra, consistent with the archaeomagnetic studies on Santorini and Crete.

inclination at the other eastern Crete site, Makrygialos, being only slightly steeper. The remanent directions at sites from central Crete (Malia, Gournia, Knossos, Sklavokambos, Phaestos and Hagia Triada) were significantly different from those in the east, yet were all mutually consistent (Table 2, Fig. 2). The same differences and similarities were then confirmed by determination of the palaeointensity of the geomagnetic field (Table 2), although such determinations are less precise. These results were unexpected as it had been thought that the final destruction levels on Crete would have had similar ages. More surprising was the observation that the directions and palaeointensities determined for central Crete were the same as those of the Plinian ashfall deposits on Santorini, while the directions of the sites in eastern Crete were the same as those of the later paroxysmal tephra deposits on Santorini. The central Crete destruction levels are archaeomagnetically synchronous with the Plinian ashfall and there is a time gap before the destructions in eastern Crete and the paroxysmal eruption of Santorini.

Conclusions

The fact that the Akrotiri hearth appears to have been last fired at some time before the destructions in Crete and also before the ashfall on Akrotiri is consistent with the archaeological evidence[36,37] that this Minoan settlement was originally destroyed by an earthquake and that partial clearance had been undertaken before it was covered by ash. However, the scatter in both directions and palaeointensities needs to be improved and this is, anyway, only one structure. The determination of reliable LMIA geomagnetic field parameters, therefore, still require examination of an undoubted LMIA destruction level. While a difference in time between the Akrotiri hearth and the basal Plinian ashes can be considered as strongly indicated, rather than confirmed, there is little doubt about the difference between both the directions and palaeointensities of the Plinian ash/central Crete sites and those of the paroxysmal tephra/eastern Crete destruction levels. However, any evaluation of the actual time represented by the age difference can only be an approximation. If the central Cretan sites and the Thera basal pumice values are combined, giving equal weight to each fired or volcanic level, then their mean direction is 356.1°, 60.0° and the 95% confidence radius is 0.9°. (Knossos is excluded because the only site that was allowed to be sampled was a kiln which may not have been fired at the time of the destruction level—although its similarity in direction and intensity suggests that it was last fired within 2–3 yr of the destruction levels at other central Cretan sites.) Combining Palaikastro, Kato Zakros and the paroxysmal Minoan tephra directions gives a mean direction of 357.1°, 54.8° and a 95% confidence radius of 2.6. The difference in direction is thus 5.2° with the summation of the 95% radii as 3.5° (calculated on a conservative level of analysis as a smaller precision is obtained when these are combined at a sample level). The difference in direction, 1.7–5.2°, is small although clear and confirmed by the palaeointensity differences. However, the rate of secular variation of the geomagnetic field is not known for this time. A few records from Bulgaria[23] span the probable age of these events, but lack of information on the precise age of the Santorini/Cretan events and errors in the ^{14}C dating for this time makes any comparison uncertain. New magnetic studies[25] of the VEMA V10-50 core of sediments from the eastern Mediterranean[5] confirm that a major tephra layer, previously attributed to the Minoan eruption on the basis of refractive indices, also has identical Fe:Ti ratios and Mn, Al, Si and Mg content in its magnetic minerals. The overlying carbonate sediments show a decrease in inclination during this period (Fig. 3) but the rate can only be calculated from sedimentation rates which are themselves only estimates. Thus the change in inclination could be some $0.07° yr^{-1}$, which is slower than the present-day total change in the regional geomagnetic field of some $0.25° yr^{-1}$. The difference in time could be between 100 and 7 yr but the longer time interval seems unlikely, and it is archaeomagnetically unlikely that the time difference could be as low as 7 yr as the observations from the tephra deposits would then show some degree of smearing. A time gap of some 20 ± 10 yr therefore seems to be the most reasonable estimate for this interval.

Implications

The mere existence of a time gap is significant. The fact that it was the central Cretan destruction levels that were archaeomagnetically synchronous with the Plinian ashfall means that the ash itself can have had little direct influence on the Minoan civilization on Crete. The thickness of the ash mantle over Santorini would probably have made it essentially uninhabitable, but only 5 cm of ash is thought to have fallen on Crete[5,6] and this was mostly in the east, where civilization appears to have continued. It seems almost certain, therefore, that the central Cretan destruction levels were caused by an earthquake—the intense burning presumably resulting from oil spills catching fire, and so forth. Knossos seems to be the only central Cretan site in which habitation continued after seismic devastation, which may imply that this area is geologically less vulnerable to earthquakes. Some 10–30 yr later, the violent eruption of Santorini was probably accompanied by tsunamis and air percussion waves. It seems unlikely that tsunamis were the direct cause of the destruction of the remaining Minoan settlements on eastern Crete as extensive fire destruction is inconsistent with such an explanation. If this 'final' event was only a few years after the Plinian ashfall, with associated earthquakes, then weakened buildings are likely to have been flattened by the percussion air wave, but a time interval of 10–30 yr would suggest that this destruction level was also associated with earthquake activity, rather than being directly caused by the

volcanic eruption. Such earthquakes would obviously be related to the increase in volcanic activity but the firing was again probably due to the seismic disturbance. Firing by invading Myceneans[38,39] immediately after the seismic destruction cannot be excluded, although the extent and intensity of burning is comparable with the central Crete destructions which are not considered to be associated with invasion.

This hypothesis for the end of the Minoan civilization has little direct bearing on postulated similarities with the Atlantis legends or with *Exodus*. Plato's descriptions do not obviously refer to volcanic activity, but are consistent with the second eruptive phase, because the end of Atlantis would then relate to the sudden end of the Minoan civilization simultaneously with the disappearance of the island of Santorini as its 80 km^2 caldera formed.

Other implications of this study include the evolution of this form of volcanic activity and the determination of tephra emplacement temperatures. Another implication is the way in which earthquakes near Crete can affect different parts of this island. This seems to be consistent with the evidence for changes in sea-level[40] which also define separate tectonic units. These, and the archaeological implications clearly require study of Minoan destruction levels at other places and times, particularly at Knossos. It would be especially valuable to extend such archaeomagnetic observations to fired levels within the well-dated Egyptian sequences, as well as Mycenae, to determine both the relative and absolute ages of these events.

We thank the Greek authorities for permission to undertake this study and for their cooperation in the field. Professor C. Doumas and the British School at Athens, especially Dr H. Catling, were particularly helpful. We thank the many archaeologists who assisted in the field or offered advice on sampling. Professors P. M. Warren, J. V. Luce and S. Hood gave helpful comments on the manuscript. The VEMA core samples were provided by the Lamont-Doherty Geological Observatory. W.S.D. was in receipt of an SERC studentship.

Cells of the yeast, Saccharomyces cerevisiae, *containing disruptions of either of two genes that are members of the* ras *oncogene family are viable, but haploid yeast spores carrying disruptions of both genes fail to grow.*

THE cellular proto-oncogenes of the transforming genes from Harvey and Kirsten murine sarcoma virus (c-*ras*^{H} and c-*ras*^{K}, respectively) represent two members of a family of related genes called *ras* (ref. 1). Activated forms of these genes have been isolated from some human cancers and/or cancer-derived cell lines that are able to transform NIH 3T3 cells in a transfection assay. Point mutations at amino acid position 12 or 61 (refs 2–9) have been shown to be necessary and sometimes sufficient for the transforming phenotype[5–7].

The *ras* gene family shows extensive evolutionary conservation[10]. Cellular *ras* genes have been found in a wide variety of vertebrates. The known range of conservation has been extended to *Drosophila melanogaster*[11] and, now, to the yeast *Saccharomyces cerevisiae*[12,13]. Recently, there have been isolated from the yeast genome two DNA fragments that cross-hybridize with a viral *ras* probe[13], while a gene located near the yeast actin and tubulin genes also shares homology with the *ras* gene family[12]. A set of *in vivo*-labelled yeast proteins are specifically immunoprecipitated by anti-*ras* monoclonal antibodies prepared against the mammalian *ras*-encoded protein, p21 (ref. 14).

The DNA sequences of the two *ras*-related DNA fragments isolated by DeFeo-Jones *et al*[13] (c-*ras*^{sc}*1* and c-*ras*^{sc}*2*) have

† Present address: E.I. duPont de Nemours & Company Inc., Experimental Station, Central Research and Development, Wilmington, Delaware 19898, USA.

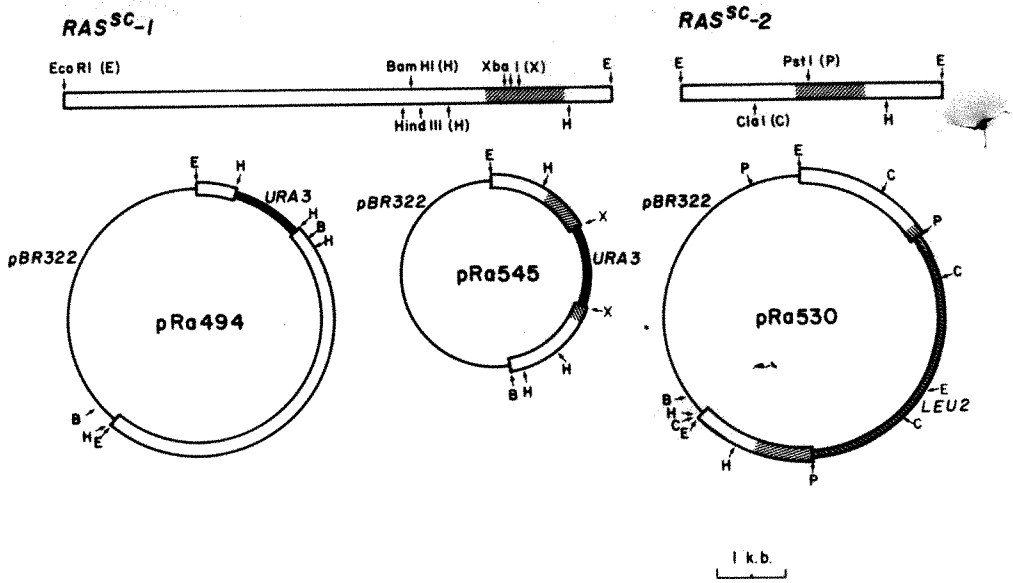

Fig. 1 *Restriction* endonuclease maps of the cloned *RAS*^{sc}*1* and *RAS*^{sc}*2* genes and recombinant plasmids used in the gene disruption experiments. The hatched portions of each map correspond to the location of the yeast *RAS* gene. The plasmids were constructed as follows: pRa545, a 1.1-kb *Hin*dIII fragment containing yeast *URA3* was ligated into the *RAS*^{sc}*1* gene, at the *Xba*I sites; pRa494, the *URA3* gene was substituted for the *Hin*dIII fragment containing *RAS*^{sc}*1* and the *Hin*dIII fragment adjacent to it; pRa530, a 4-kb *Pst*I fragment containing the yeast *LEU2* gene was ligated into the *Pst*I site within the *RAS*^{sc}*2* coding sequence. DNA restriction fragments to be subcloned were gel-purified and ligated using published procedures[34]. The *URA3* gene present in pRA545 and pRa494 and the *LEU2* gene in pRa530 were derived from YEP24 (ref. 35) and YEP13 (ref. 36) respectively. To construct pRa545, the two small *Xba*I fragments present within *RAS*^{sc}*1* were replaced by a *URA3*-containing *Hin*dIII fragment. This was accomplished by filling-in the protruding 5′ ends of the DNA fragments with DNA polymerase I (large fragment) and then flush end-ligating the fragments together. This recreates *Xba*I endonuclease restriction sites at the junctions.

been determined and are presented elsewhere[15,16]. Sequence analysis of the two genes, designated *RAS*^{sc}*1* and *RAS*^{sc}*2*, reveals open reading frames of 309 and 322 amino acids respectively. The putative proteins encoded by these reading frames are highly homologous to each other for the first 180 amino acids, at which point they diverge. Homology is again found at the extreme C-terminal end of each peptide. A striking pattern of amino acid sequence homology is also found when the putative yeast proteins are compared with the mammalian *ras* protein, p21. The NH_2-terminal 170 amino acids of the yeast and mammalian proteins are >60% homologous. The fact that such evolutionarily divergent organisms exhibit such extensive sequence conservation suggests that the *RAS* gene products fulfill an essential role in cell growth and metabolism. Here we show that the two yeast *RAS* genes isolated by D. DeF.-J. *et al.*[13] constitute an essential gene family. At least one functional member of the family is required for spore germination and probably for cell growth.

Viability of yeast strains

We have constructed null mutations in the *RAS* genes to test directly the phenotype of cells lacking these genes. These experiments use yeast transformation techniques which have been developed recently (reviewed in ref. 17). In yeast, introduction of exogenous DNA into the genome requires homology between the recipient chromosome and the donor fragment. This requirement allows one to direct DNA fragments to specific sites within the yeast genome. We have used these transformation systems to integrate disrupted *RAS* genes into the yeast genome, excluding the wild-type genes in the process.

Figure 1 shows the restriction maps of cloned *Eco*RI fragments containing *RAS*^{sc}*1* and *RAS*^{sc}*2*. Part or all of these two restriction fragments have been used to construct a series of recombinant plasmids containing the wild-type *URA3* or *LEU2* gene. Two mutations were constructed in *RAS*^{sc}*1* (Fig. 1). The first, contained in plasmid pRA494, harbours a 1.1-kilobase (kb) *Hin*dIII restriction fragment which encodes *URA3*, substituted for 2.3 kb of *RAS*^{sc}*1* DNA. This deletion lacks the entire *RAS*^{sc}*1* gene plus an additional 1.1 and 0.2 kb of noncoding sequence 5′ and 3′ to *RAS*^{sc}*1*, respectively. The second mutation, in plasmid pRA545, contains the *URA3* gene in place of two small *Xba*I restriction fragments located within the *RAS*^{sc}*1* open reading frame (Fig. 1). This deletion spans amino acids 63–150 of the putative *RAS*^{sc}*1* coding sequence. A single disruption of *RAS*^{sc}*2* was constructed in plasmid pRa530 by inserting a 3.8-kb *Pst*I restriction fragment, encoding *LEU2*, into a *Pst*I site that corresponds to amino acid 65 in the *RAS*^{sc}*2* open reading frame. These insertions should therefore disrupt the *RAS*^{sc} gene products.

Plasmids pRa494, pRa530 and pRa545 were digested with the appropriate restriction endonucleases to generate DNA fragments containing *RAS* DNA flanking the *LEU2* and *URA3* insertions. These conditions lead to replacement of the wild-type locus with the transforming sequence as outlined in Fig. 2 (ref. 18). As it is possible that the *RAS* genes encode essential functions, the restricted plasmids were introduced into a diploid strain homozygous for *ura3* and *leu2* (TX2).

To identify those transformants having the desired molecular structure, genomic DNA was prepared from pRa494, pRa530 and pRa545 transformants and analysed by the method of Southern[19] (Fig. 3*a*). Most of the transformants give hybridization patterns consistent with the simple replacement in one chromosome homologue of the wild-type locus by the null or the disruption mutation. *RAS*^{sc}*1* is contained on a 2.9-kb *Bam*HI–*Eco*RI restriction fragment. In the pRa545-derived mutations this fragment expands to 3.8 kb, due to the insertion of the *URA3* gene. In the pRa494 mutation the fragment size decreases to 1.8 kb, due to the deletion of the entire *RAS*^{sc}*1* locus. These structures are shown in Fig. 3*b*, together with analogous diagrams for the wild-type and mutant *RAS*^{sc}*2* genes. The hybridization data for transformants of pRa545, pRa530 and pRa494 (Fig. 3*a*) are consistent with the structures outlined in Fig. 3*b*. In each case, the transformants contain a wild-type *RAS*^{sc}*1* allele on one chromosome and the null or disrupted allele on the other.

The phenotypes of haploid yeast strains lacking a functional copy of either *RAS*^{sc}*1* or *RAS*^{sc}*2* were determined in haploid meiotic segregants derived from the transformants. The meiotic cell cycle in yeast is initiated when diploid strains are placed on a nitrogen-deficient medium containing a nonfermentable carbon source. The end product of each meiotic event is four haploid spores, collectively called a tetrad. As the *ras* mutations are heterozygous in the diploid transformants, two spores in every tetrad will contain the mutant *ras* allele and two will contain the wild-type allele. The *ras*^{sc}*1* mutations are associated with *URA3* and the *ras*^{sc}*2* mutation is associated with *LEU2*, so that Ura$^+$ and Leu$^+$ haploid spore clones mark those haploid segregants that lack a functional copy of *RAS*^{sc}*1* or *RAS*^{sc}*2*

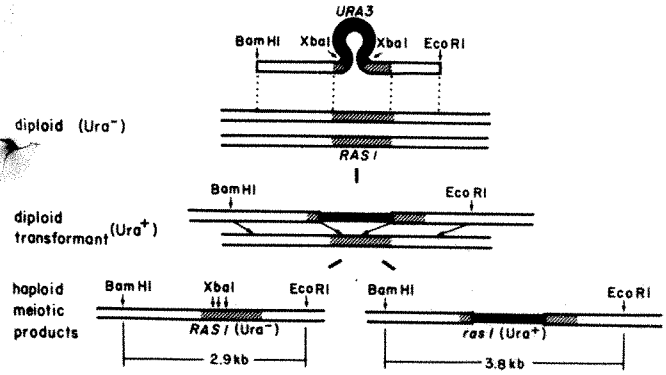

Fig. 2 Schematic drawing of the transformation of diploid strain TX2 with the *Eco*RI–*Bam*HI *RAS*^{sc}*1* fragment of pRa545. The linear fragment integrates into the yeast chromosome at *RAS*^{sc}*1*, giving rise to a heterozygous mutation in *RAS*^{sc}*1*. Sporulation of this diploid gives rise to haploid spores containing either the wild-type or mutant *RAS*^{sc}*1* locus. Strain TX2 was transformed with linear restriction fragments by the method of Beggs[37]. Gene disruptions 494 and 530 were created in a similar manner by transforming TX2 with *Eco*RI-restricted pRa-494 or *Xba–Hin*dIII-restricted pRa530 and selecting for uracil or leucine prototrophy, respectively.

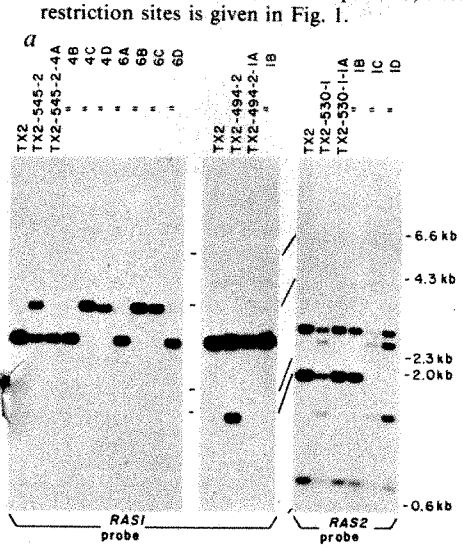
respectively; this is outlined schematically in Fig. 2. The recovery of Ura$^+$ and Leu$^+$ segregants from TX2-545 and TX2-530, respectively, indicates that the *ras*^{sc}*1-545* and *ras*^{sc}*2-530* mutations do not result in cell inviability. The Ura$^+$ and Leu$^+$ phenotypes segregate normally through meiosis and Ura$^+$ or Leu$^+$ spores have no apparent growth disadvantage on the rich medium used for the analysis. It seems, therefore, that neither *RAS*^{sc}*1* nor *RAS*^{sc}*2* is separately essential for ascospore germination and growth. Southern analyses of tetrads from TX2-545 or TX2-530 (Fig. 3*a*) show that the Ura$^+$ and Leu$^+$ spore clones contain only the mutant copy of *RAS*^{sc}*1* or *RAS*^{sc}*2*, respectively.

The fact that both *RAS* genes are not required for vegetative growth (mitotic cycle) does not exclude the possibility that both are required for meiosis. To test this, we have constructed diploid strains homozygous for either the *ras*^{sc}*1-545* or *ras*^{sc}*2-530* allele. In both cases these diploids sporulated normally, giving rise to a high proportion of asci with four spores. This indicates that meiosis is normal when the products of one or other of the genes *RAS*^{sc}*1* and *RAS*^{sc}*2* are absent.



Unlike TX2-545 and TX2-530, transformants derived from pRa494 are heterozygous for a lethal mutation, as only two viable spores in each tetrad of TX2-494 are recovered. Those spores containing the deletion, marked by *URA3*, do germinate, but undergo only one to three rounds of cell division. The fact that the deletion in TX2-494 includes >1 kb of DNA upstream of the *RAS*^{sc}*1* gene, and the observation that internal disruptions in the *RAS*^{sc}*1* and *RAS*^{sc}*2* open reading frames are not lethal, suggests that some essential function separate from *RAS*^{sc}*1* lies at least partially within the *ras*^{sc}*1-494* deletion.

Spore viability

Our results suggest that neither *RAS*^{sc}*1* nor *RAS*^{sc}*2* separately has an essential function, since no phenotypic change is associated with haploid strains lacking either a functional *RAS*^{sc}*1* or *RAS*^{sc}*2* gene. Neither gene alone is absolutely required for either the mitotic or the meiotic cell cycle. But it is possible that the two *RAS* genes may code for proteins with overlapping but not necessarily identical functions. To test this possibility, we constructed a diploid, EG53, that is heterozygous for both the *RAS*^{sc}*1* and *RAS*^{sc}*2* disruptions by mating a Ura$^+$ haploid segregant from TX2-545 (*RAS*^{sc}*1* disruption) with a Leu$^+$ haploid segregant from TX2-530 (*RAS*^{sc}*2* disruption). Tetrad analysis was performed on the resultant meiotic progeny.

Because *RAS*^{sc}*1* and *RAS*^{sc}*2* are unlinked (see below), the two genes should segregate independently in meiosis, and give rise to recombinant spores (Ura$^+$, Leu$^+$ and Ura$^-$, Leu$^-$) frequently. However, no Ura$^+$ Leu$^+$ recombinants were recovered in 60 tetrads analysed, although Ura$^-$, Leu$^-$ segregants were frequently observed. Moreover, as shown in Table 1, a peculiar pattern of spore germination was observed in the dissected tetrads. Relatively few tetrads with four viable spores were recovered (7/60), whereas ascopore germination in related crosses was good (Table 1). These seven tetrads are parental with respect to *URA3* and *LEU2* in the sense that none of the spores was recombinant. Similarly, many more asci with three viable spores per tetrad are recovered in EG53 (30/60) relative

Fig. 3 *a*, Southern blot analysis of gene disruptions in *RAS*^{sc}*1* and *RAS*^{sc}*2*. The 10 lanes in the first panel correspond to genomic DNA from parent (TX2), heterozygous transformant TX2-545-2 and haploid spore clones from two tetrads of TX2–545-2. Haploid spore clones 4A, 4B, 6A and 6D were Ura$^-$, while spore clones 4C, 4D, 6B and 6C were Ura$^+$. The four lanes in the second panel correspond to DNA from parent, transformant 494-1, and two haploid spore clones from a tetrad of TX2-494-1. Only haploid spores containing the wild type *RAS*^{sc}*1* gene grow into colonies. DNA in the first two panels was digested with *Bam*HI and *Eco*RI and probed with nick-translated *RAS*^{sc}*1* DNA (*Eco*RI–*Bam*HI fragment). In the third panel the six lanes correspond to DNA from the parent, pRa530 transformant (TX2-530-1), and spore clones from a tetrad of the transformant. DNA was restricted with *Cla*I and *Hin*dIII and probed with *RAS*^{sc}*2* nick-translated DNA (*Eco*RI fragment). Spore clones 1A and 1B are Leu$^-$ while spore clones 1C and 1D are Leu$^+$. The migration positions of the phage λ-*Hin*dIII restriction fragment are indicated to the left of the third panel. *b*, Restriction endonuclease maps of *RAS*^{sc}*1*, *RAS*^{sc}*2* and gene disruption present in *a*. The key to the restriction sites is given in Fig. 1.

Methods: Genomic yeast DNA was isolated using a published procedure[38], restricted with the appropriate restriction enzymes, electrophoresed through 0.7 agarose in Tris-borate EDTA buffer[39], and blotted onto nitrocellulose[40]. The nitrocellulose was hybridized with ^{32}P-labelled nick-translated DNA in a solution of 6× SCP (1× SCP = 0.1 M sodium chloride, 0.03 M sodium phosphate, 0.001 M EDTA, *p*H 6.2), 0.1% *N*-lauroyl sarcosine, 0.06 mg ml^{-1} sonicated calf thymus DNA for 16–24 h at 65 °C. The filter was washed sequentially twice for 10 min each at 60 °C in 2× SCP, 0.01% SDS and 2× SCP. Autoradiographs of filters were made using Kodak X-omat R film.

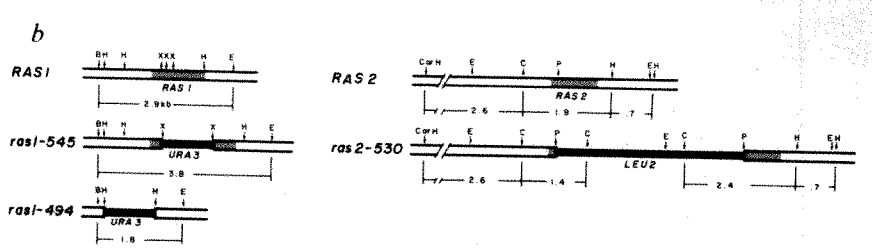


Table 1 Lethal segregation patterns of *RAS* disruptions

Disrupted *RAS* gene	Strain	Viable spores per tetrad: 4	3	2	1	0	% Germination of spores with *RAS* disruptions
—	TX2	27	3	0	0	0	
RAS1	TX2-545-2	24	2	1	0	0	48 (Ura^+ spore clones)
RAS1	TX-545-3	6	0	0	0	0	50 (Ura^+ spore clones)
RAS2	TX2-530-1	16	5	3	1	0	48 (Leu^+ spore clones)
RAS2	TX2-530-2	4	2	1	0	0	50 (Leu^+ spore clones)
RAS1	TX2-494-2	0	0	65	11	4	0 (Ura^+ spore clones)
RAS1, RAS2	EG53	7 (7PD)	30 (29T)	20 (13NPD)	3	0	0 (Ura^+, Leu^+ spore clones)

Spore viability of diploid strains heterozygous for *ras* disruptions. EG53, heterozygous for *RAS1* and *RAS2* disruptions, was constructed by crossing Ura^+ and Leu^+ haploid segregants from TX2-545 and TX2-530 respectively. In EG53 all asci containing four viable spores were parental ditype (PD) for Leu^+ and Ura^+, 29/30 asci containing three viable spores were tetratype (T) and 13/20 asci containing two viable spores were non-parental ditype (NPD). The seven asci with two viable spores that are not non-parental ditype are the result of nonspecific spore lethality.

to the related crosses. In most of these tetrads (29/30), *URA3* and *LEU2* are in the tetratype configuration (one of each parental and one of each recombinant type). By inference, the inviable spore is always the Ura^+, Leu^+ recombinant. There is also a disproportionately high number of tetrads with only two viable spores (20/60), and most of these asci (13/20) are non-parental (all of the spores are recombinant) with respect to *URA3* and *LEU2*. Again the inviable spores in these 13 tetrads are inferred to be those with both disrupted *RAS* genes (the Ura^+, Leu^+ spores). The results of this analysis demonstrate a striking correlation between the observed lethal segregation pattern and the segregation of the two mutant *RAS* genes, and provide strong evidence that the double mutant (Ura^+, Leu^+) causes lethality in haploids. These data, therefore, indicate that the *RAS^{sc}1* and *RAS^{sc}2* genes encode an essential function.

Visual inspection of the inviable spores reveals that not only do they fail to undergo a single round of cell division, but they also fail to form buds. Since bud emergence in vegetatively growing cells and germinating spores occurs early in the S phase of the cell cycle[20], this observation suggests that the inviable spores may be blocked quite early in the cell division cycle. The inviability, however, does not distinguish between a function for *RAS* that is specifically related to the cell cycle *per se* as opposed to a general role in cell growth and/or spore germination. Note also that this lethal spore phenotype is quite different from that observed for the lethal segregants of TX2-494. In the latter case, the spores were able to germinate and undergo one to three rounds of cell division before mitotic growth ceased. This phenotypic difference further supports the notion that the lethal mutation in TX2-494 is not in the *RAS^{sc}1* gene.

RAS^{sc}1 is located on chromosome XV

During the genetic analysis of the *RAS^{sc}1* mutants, we observed genetic linkage between *RAS^{sc}1* and *ade2*, 13 recombination units, on the right arm of chromosome XV. Additional mapping data between *pet17* and the mutant *ras^{sc}1* locus place the *RAS^{sc}1* centromere proximal to *ADE2* (see Table 2). A temperature-sensitive (ts) lethal mutation *tsm8740*, has recently been mapped to chromosome XV, 13 centimorgans from *ade2* (ref. 21).

Table 2 Mapping data for *RAS1* and strain list

Strain	Map interval	Ascus type: PD	NPD	T	Map distance (centimorgans)
TX2-494-2	Lethal-*ade2*	34	0	12	12.4

Results of tetrad analysis on strains containing the *ras^{sc}1-494* allele. Genetic procedures are standard[31] and the sporulation plate media are described elsewhere[32]. DCX102 and DCX103 were derived from mating haploid segregants of a *ras^{sc}1-494* strain to K381-9D and K382-19D immediately after dissection. This lethal rescue technique is described elsewhere[33]. The *tsm8740* allele in EG45-7D was derived from Be326.

Although we find that this mutation is tightly linked to *RAS*^{sc}*1*, less than 1 map unit distant (unpublished observations), it is not allelic to *RAS*^{sc}*1*. This has been determined by mating a haploid strain bearing *tsm8740* (EG45-70) with a haploid containing the large *RAS*^{sc}*1* deletion from TX2-494. (Although spores containing the *ras*^{sc}*1-494* deletion fail to grow into colonies, they can be mated immediately after germination.) The resulting diploid strain, doubly heterozygous for *tsm8740* and the *ras*^{sc}*1-494*, is not temperature-sensitive for growth, indicating that *tsm8740* is complemented by the wild-type allele on the ras^{sc}*1-494* chromosome. Similar mapping experiments indicate that *RAS*^{sc}*2* is unlinked to *ADE2* and *RAS*^{sc}*1*; its precise location has not yet been determined.

Conclusions

The data presented here demonstrate that *RAS*^{sc}*1* and *RAS*^{sc}*2* encode an essential function in yeast. The viability of yeast cells containing disruptions of either of these genes indicates that the function(s) specified by either is sufficient to support both mitotic and meiotic cell division cycles, but that at least one wild-type gene is required for viability. There is no apparent correlation between the rates of spore germination or growth and the disruption of either *RAS* gene.

The inability to recover ascosporal clones that contain both mutant *RAS* genes indicates that the two genes encode proteins with similar if not identical functions. Our results do not exclude the possibility that *RAS*^{sc}*1* and *RAS*^{sc}*2* have separate functions as we have observed growth rates only under a limited set of conditions. However, these results do show that the *ras*-related sequence identified by Gallwitz and colleagues[12] does not specify the same function as *RAS*^{sc}*1* and *RAS*^{sc}*2*, as the sequence fails to complement the defect of the double *RAS* mutant. A situation in which two unlinked genes have nearly identical functions exists for several other yeast genes. Histones H2A (ref. 22) and H2B (ref. 23), and the ribosomal protein p51 (ref. 24) are encoded by two unlinked genes. Disruption of only one of the gene pair generally causes no phenotypic change while disruption of both genes has severe consequences on cell viability. Although untested, it is likely that histones H3 and H4 (ref. 25), glyceraldehyde 3-phosphate dehydrogenase[26], and several other ribosomal proteins which have two structural genes[27] may fall into this category of duplicated essential genes.

The results obtained from the analysis of one of the *RAS*^{sc}*1* mutations, *ras*^{sc}*1-494*, suggests that another essential cellular function is tightly linked to *RAS*^{sc}*1*. That this essential gene is not *RAS*^{sc}*1* is suggested by several lines of evidence. First, the deletion defined by this mutation extends 1.1 kb 5′ and 0.2 kb 3′ beyond the *RAS*^{sc}*1* coding sequence, and therefore includes more than just *RAS* DNA. Second, an internal *RAS*^{sc}*1* deletion in the highly conserved region of amino acid homology does not by itself result in cell lethality. Spore inviability is observed only in cells that carry this internal mutation in conjunction with the *ras*^{sc}*2* disruption. Third, the lethal phenotype of *ras*^{sc}*1-494* spores is quite different from that of the *ras*^{sc}*1 ras*^{sc}*2* double mutants. Spores containing *ras*^{sc}*1-494* germinate and undergo one to three rounds of cell division before growth is arrested, whereas *ras*^{sc}*1 ras*^{sc}*2* spores fail to divide or initiate bud formation. Although these data do not exclude other explanations, the most likely interpretation is that another essential gene resides in close proximity to *RAS*^{sc}*1*.

Comparison of the presumed amino acid sequences of *RAS*^{sc}*1* and *RAS*^{sc}*2* reveals a very large region of non-homology that is flanked by highly homologous amino acid sequences. The NH_2-terminal 180 amino acids are 83% conserved but the next 100 amino acids show only 20% conservation[15,16]. The proteins again show a high degree of homology at their C-terminal nine amino acids. Despite this large divergent region, however, the two gene products complement each other. This lack of selective pressure can be accounted for if the diverged portions of the *RAS* polypeptides are removed proteolytically, an event that is known to occur in the C-terminal region of the mammalian *ras* genes[28,29]. Alternatively, these portions of the yeast proteins may encode a function not particularly dependent on primary sequence. It may be noteworthy that the divergent region of each putative *RAS* polypeptide does show a similar amino acid composition.

Judging from the extreme evolutionary conservation of the *ras* genes, it is not surprising to find that their products have a vital role in cell growth or metabolism in yeast. What does this analysis suggest this role might be? The failure of *ras*^{sc}*1 ras*^{sc}*2* double mutants either to germinate or to form buds suggests that the *RAS* gene products are required early in the cell division cycle. These data are also consistent with the proteins being quite rare and/or highly susceptible to proteolysis during the sporulation process. More extensive knowledge about *RAS* function(s) awaits the isolation and analysis of conditional mutations in *RAS*.

We thank Drs Francois Hilger and Kathy Wadell for providing some of the yeast strains, and Donna Lane for expert typing. This work was supported in part by a grant from the General Medical Council of the NIH (GM29473) to K.T.

Recent studies of dwarf novae in the UV and X-ray regions have suggested that much of the energy produced in a dwarf nova is emitted in the far-UV and extreme-UV regions (100–1,200 Å). We report here on observations of SS Cyg and U Gem obtained with the Voyager UV spectrometers (UVS) in the 500–1,200 Å region. SS Cyg has been detected in quiescence at a flux level of 9×10^{-13} erg cm^{-2} s^{-1} Å^{-1} at 1,000 Å. U Gem was not detected in quiescence. No emission shortward of the Lyman limit (912 Å) is detected in either star. Observational upper limits to the extreme-UV flux in the 540–740 Å band from SS Cyg and U Gem correspond to 2×10^{-13} erg cm^{-2} s^{-1} Å^{-1}. A far-UV (λ_{eff} = 1,050 Å) light curve for an outburst in SS Cyg is presented. The slope of the far-UV flux distribution during the rise to maximum is observed to be correlated with the UV brightness. The nature of this correlation supports the suggestion that the outburst begins at the outer edge of the accretion disk and moves inward. The far-UV flux distributions of SS Cyg and U Gem in outburst were found to be remarkably similar, both exhibit a substantially flatter ($F_\lambda \propto \lambda^{-0.5}$) distribution than that observed in the IUE–UV ($F_\lambda \propto \lambda^{-2.3}$). This result is contrary to current disk models which predict a continued rise in flux in the far-UV. Evidence for a wind in the Lyman lines of hydrogen is seen in SS Cyg. No evidence of a wind was observed in U Gem.

The UVS[1] on board Voyagers 1 and 2 are nearly identical objective grating instruments having maximum sensitivity in the 500–1,200 Å region and a dispersion of 9.26 Å per detector channel (resolution ~20 Å). Previous stellar observations and the absolute calibration have been discussed by Holberg *et al.*[2]. A decline in detector sensitivity towards longer wavelengths establishes ~1,200 Å as a practical long wavelength limit for observing sources of the brightness of SS Cyg and U Gem. We have therefore restricted analysis of Voyager data to wavelengths shortward of 1,175 Å.

SS Cyg has been observed with the UVS during two outbursts and U Gem during one outburst. Table 1 lists the dates of observation and the characteristics of these outbursts. In quiescence, SS Cyg has been detected at the 2σ level in the 1,000 Å region at a flux level of 9×10^{-13} erg cm^{-2} s^{-1} Å^{-1}. U Gem has not been detected in quiescence with the Voyager UVS. During the intervals listed in Table 1, the Voyager scan platform was fixed in the direction of the target, while the spacecraft limit cycle motions allowed the field of view of the spectrometer to wander on and off the target to obtain both source and background signals. Except for the investigation of the change in the slope of the flux distribution in SS Cyg during the rise to maximum on JD 2444373, only on-axis (±0.02°) source spectra are discussed here. For that investigation marginally off-axis (±0.04°) spectra were combined with adjacent (in time) on-axis spectra. Tests of UVS spectra show that the relative distribution within a spectrum is unaffected by it being obtained off-axis. Thus, this technique results in an improved signal-to-noise ratio within the spectrum at the expense of absolute photometry.

The far-UV light curve of the first outburst (JD 2444373) in SS Cyg is presented in Fig. 1. The light curve was generated by averaging the 925–1,175 Å flux for on-axis spectra. Whenever possible, spectra closely spaced in time were combined. During the rise to maximum this time 'window' was set at 1 h. For the remainder of the outburst, time bins up to 12 h were used. Also plotted in Fig. 1 is the ratio of the flux in the long wavelength channels (1,090 ± 40 Å) to the short wavelength channels (960 ± 40), Lyβ is excluded from both bands. The second outburst observed with the UVS exhibited no significant change in flux throughout the 4 days of visual light curve. A mean 1,050 Å flux of $3.00\pm0.10\times10^{-11}$ erg cm^{-2} s^{-1} Å^{-1} was measured with a $F_{950}/F_{1,090}$ ratio of 0.97 ± 0.05. The observations of U Gem during maximum also showed no significant change during the 5 days of observation. The mean 1,050-Å flux and $F_{950}/F_{1,090}$ ratio were respectively $1.42\pm0.10\times10^{-11}$ erg cm^{-2} s^{-1} Å^{-1} and 1,03 ± 0.05. The U Gem data were also explored for variability coupled to the orbital period of 4.25 h (ref. 3). No variations in flux >5% were detected.

The far-UV light curve is similar in shape to the observed visual light curve (J. A. Mattei, personal communication)[4]. The rise in the far-UV seems to be delayed by 0.5–1.0 days with respect to the rise in the visual. Large uncertainties in the times of the UV and visual rise to maximum preclude any discussion of the possible delay. However, it is clear that in the earliest stages of the outburst the rise in flux at shorter UV wavelengths (960 Å) is delayed relative to that at longer UV wavelengths (1,090 Å). This is consistent with the observations of VW Hyi by Hassall *et al.*[4] and strongly supports their suggestion that the outburst is initiated at the outer edge of the disk and moves inward. During the decline to quiescence there is a suggestion in the Voyager data that the drop at 960 is more rapid than that at 1,090 Å. The difference is less pronounced than that observed during the rise and will require further observation to confirm its existence.

Figure 2 shows composite outburst flux distributions for SS Cyg and U Gem. The far-UV data for SS Cyg are from the

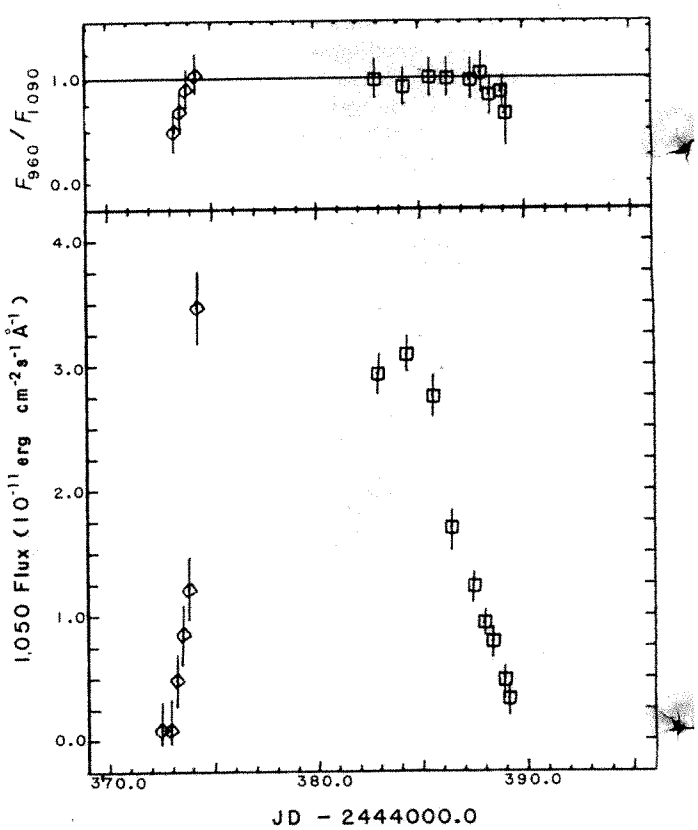

Fig. 1 Far-UV light curve and hardness curve for SS Cyg. Error bars indicate $\pm2\sigma$. ◇, Voyager 1; □, Voyager 2.
